The table is notched at *H*, to let in one side of the pipe. This notch is also seen at *R*, in fig. 24. The pipe is fastened in this place by an iron plate *c f*, fig. 31, about one eighth of an inch thick, which is fixed upon the table by two flat-headed screws near *c* and *f*. This piece is represented by itself in fig. 32, *m n*; fig. 31, is a piece of iron, at least one sixth of an inch thick, fastened by two screws, at *N*, against the side of the piece of wood *A B*, into which the thickness of this iron is let, as may be seen at *m*, in such manner that the outward surface of this piece *m n*, is level with that of the piece of wood *A B*. The pipe is fastened against this piece of iron *m n*, by a belt fixed by two screws to the piece of iron *m n*. This belt is represented by itself in fig. 33.

Of the Standards, Plate XI.

In the notches *Æ W* at the two ends of the table, fig. 2, Plate X. are placed two standards, represented in perspective in fig. 34, Plate XI. with the two ends of the table, of which the middle is suppressed, as needless in this representation. These two standards being exactly alike, it will be sufficient to describe one of them.

In each standard may be distinguished three parts, namely, the head, which reaches from the line *p a* to the top of the moulding *b d s*; the base, which extends from the top

b d s of the moulding, to the under part of the shoulder *f u q*; and the tail or tenon, which begins at the bottom of the shoulder.

All the sides of this standard are at right angles to each other, excepting only the two indentures *p* and *a* in the head, and the mouldings at the base. The inner surface *A B*, which faces the other standards, is every where an even plane.

The head is three inches and a quarter wide, from *b* to *d*; two inches and one sixth thick, from *d* to *s*; and seven inches high, from the line *b d* to the line *p a*.

The base is four inches and five sixths wide from *f* to *u*; two inches and five sixths thick from *u* to *q*; and two inches and a half in perpendicular height from *f u* to *b d*.

The tail or tenon, which proceeds from the lower middle of the base, is equal in breadth *g h*, to the breadth *u q* of the base, that is to say, it is two inches and five sixths wide. Its length, *t g*, is six inches and a quarter. Its thickness is the same as the width *P L* (fig. 24.) of the notch in the end of the table, which receives the tenon; that is to say, one inch and seven twelfths. The hole or mortise *k n* is in the middle of the breadth of the tenon, and forms a right angled parallelogram, two inches long from *m* to *k*, and eleven twelfths of an inch wide from *n* to *m*. The height of this hole is determined by the thickness of the table, in such manner, that the distance between the bottom *f u q* of the base, to the top *n m* of the hole, is somewhat less than the thickness of the table.

Each standard is fastened to the table, as may be seen in the figure, in the same manner as a common turning lathe is fastened, by a key *D*, about eight inches and a half long, driven tightly up to its middle, in that part of the mortise which is under the table; and for greater solidity, one of the keys is put in at the fore part of one mortise, and the other at the hind part of the other.

A round hole, one inch and five twelfths in diameter, is bored through the head of the standard, near *A*. The center or axis of this hole is exactly in the middle of the breadth of the head, and the hole is made through it exactly horizontal to the upper surface of the table, or, in other words, perpendicular to the side of the standard. The pipe *n o* of the ferule, fig. 35, is put into this hole. The diameter of this pipe is the same as that of the hole. The pipe *n o*, is of one piece with its scutcheon *a b d*, which is one-third of an inch thick: its breadth *a b* is one inch and five-sixths, and its length *b d* is three inches. All its surfaces are at right angles, and parallel to each other. The axis of this pipe is in the middle of its scutcheon, and perpendicular to its surface. Both the scutcheon and the pipe (being but one piece) are bored through with the same hole, which is five-sixths of an inch in diameter; and in the upper surface of the inside of this hole is a groove, which reaches from one end to the other. One end of it is seen at *n*, and its use will soon then be shown. The end *n o* of this pipe is put into the hole *A* of the standard (fig. 34.) At the inner side *A B* of this standard, and the scutcheon *a b d* (fig. 35.) is let into this surface at *c i* (fig. 34.) where it is fastened by two screws, of which the end s are seen at *c* and *i*, in this figure, and at *c* and *r* in the adjoining representation of the outside of the other standard. The two small holes in the scutcheon are female screws, to receive the ends of the screws before mentioned, which are one-third of an inch in diameter, and their heads are two-thirds. The outer surface *c i* of the scutcheon is made to lie exactly even with the inner surface of the standard, and the center of its pipe is at the perpendicular height of five inches, and seven-twelfths above the surface of the table. These two pipes (one in each standard) are destined to receive the two pivots *a b*, *g h*, of an iron axis; and the groove *n*, (fig. 35.) then becomes useful, by affording the means of introducing a little oil, to keep the pivots from losing their temper by their friction, and to make them turn with the greater ease.

The scutcheon and its pipe should be cast in one piece of good metal, sufficiently hard, but by no means brittle.

Of the Axis, and the Pieces which are fastened to it, Plate XII.

The pivots are of the same diameter as their holes; and their shoulders *b* and *h* (fig. 36.) are at the same distance from each other as the inner surfaces of the standards, that is to say, two feet.

The axis is represented naked in fig. 36; but the several

pieces represented separately in figures 37, 38, 40, 41, 42, 43, 44, 45, and 46, are to be fastened to it.

Fig. 39 represents all these pieces fixed upon the axis. It is to be observed here, that the long pivot *c* (fig. 39.) goes through the hole of the standard which is on the left-hand side of the drill, and the pivot *r* through the standard on the right-hand; so that all these figures exhibit a front view of the axis and its pieces.

The pivot *a b* (fig. 36.) on the right-hand side, is one inch and a quarter long; and that on the left, *b g*, about two inches. The diameter of the axis towards the shoulder *b* and *h* is one inch and a twenty-fourth part of an inch. From thence it thickens gradually to near the middle of its length, in order to facilitate the fixing of the pieces which are to be slipped on, over its two ends. In the middle, its diameter is one inch and an eighth.

The first piece which is slipped over its end *g* (fig. 36.) is represented in perspective in fig. 37: a section of it is seen in fig. 38, and it appears in profile at *g a b q* in fig. 39. It is a hollow cylinder, of which the outer diameter *a b* (fig. 37.) is one inch and thirteen twenty-fourths of an inch. It has a shoulder, of which the total diameter *e d* (fig. 38.) or *g q* (fig. 36.) is three inches and five twelfths. Its thickness from *a* to *b* (fig. 31.) is seventeen twenty-fourths of an inch; and the thickness *n m* of the shoulder is one-sixth of an inch. This hollow cylinder and its shoulder are made of the same piece of brass, cast in a mould, and afterwards turned. The diameter of the hollow of this cylinder is the same as that of the middle of the axis, upon which it goes very tightly, and is fastened, as in fig. 39. by a riveted pin *n*, one-sixth of an inch in diameter, which passes through the axis and the cylinder. This cylinder is placed in such manner that its rim *a b* is eight inches and fifteen twenty-fourths of an inch distant from the shoulder *e* of the axis, fig. 39, or from the shoulder *b* (fig. 36.)

After this cylinder is firmly fixed, another hollow cylinder, represented in perspective in fig. 40, is forced over the end *g* of the axis fig. 36. Its end *g* is put on first, and forced forward, till the edge of its other opening *a b* (fig. 40.) is about a twelfth part of an inch beyond the shoulder *h* of the axis fig. 36. The reason for putting it thus a little beyond the shoulder *h*, is, that it may not touch the pipe of the standard when it turns.

This cylinder (fig. 40.) has, nearly in the middle of its length, a shoulder, of which the flat side *f d*, which is also represented in full view in fig. 41, forms a circle perpendicular to the axis of the cylinder. This circle or shoulder is four inches in diameter, and a quarter of an inch thick towards its edge; but it is thicker towards the middle, as is seen in its profile at *d* (fig. 39.) The whole length of the cylinder between its two ends *a b* and *g* (fig. 40.) is three inches; and the diameter of its thickness at each end, *a b* and *c*, is one inch and five-twelfths: the length *n a*, from the end *a b* to the flat side *d f* of the shoulder, is one inch and nine twenty-fourths.

This cylinder and its shoulder are of one piece of brass, cast in a mould, and turned in a turner's lathe. When put upon the axis, over which it goes very tight, in such manner that, as was said before, its end *a b* (fig. 40.) is placed about a twelfth part of an inch within the shoulder *h* of the axis (fig. 36.) It is fastened by a pin which goes in at the hole *c* (fig. 40.) and passes through the axis. This pin, which is of iron, and one-sixth of an inch in diameter, goes tight through the cylinder and the axis, without projecting at either of its ends. The cylinder is represented as pinned at *N* (fig. 39.)

Fig. 42, is a wooden pulley, of which a part is seen at *P*, (fig. 1, Plate X.) and of which the hole in its center is of the same diameter as the end *a b* of the cylinder (fig. 40, Plate XII.) This end of that cylinder is put through this pulley; which is every where one inch and a quarter thick, that is to say, somewhat less than the length of the end *n a* of the cylinder (fig. 40); so that when the pulley is put upon the cylinder, and its side is placed against the shoulder *d f*, the end *a b* of the cylinder projects a little beyond the other side of the pulley, to prevent its rubbing against the adjoining standard. This pulley is represented in profile at *l m* (fig. 39.) Its extreme diameter, *j k*, is eight inches; and its groove *l m*, which is square, is an inch and a quarter deep, and three quarters of an inch wide. This pulley is placed close to the brass scutcheon, to which it is fastened by three screws *A*, *B*, *C*, (fig. 42.) which screws into the

the three holes *a*, *b*, *c*, (these being female screws) in the flat part of the shoulder (fig. 41.) of the cylinder (fig. 40.) Each of these screws (fig. 42.) is from a quarter to a third part of an inch in diameter; and their head, which is flat, is about a quarter of an inch thick, and two-thirds of an inch in diameter. These heads are screwed into the holes *a*, *b* and *c*, till they lie even with the surface of the pulley on that side.

To the other end *b* of the axis (fig. 36.) is fitted exactly, though so as to slip on with ease, a third hollow cylinder (fig. 43.) of which the profile is seen at *b* (fig. 39.) It is like that which is marked *N* *d* at the other end of the axis; with this only difference, that the extreme diameter of the end *b* *c* of the cylinder (fig. 43.) is about two inches. This cylinder is fastened to the axis by a thumb-screw *e*, which goes through a female screw in the cylinder, and of which the end enters into the hole *l* in the axis (fig. 36.) which is not a female screw: and that the end of the screw may be directed to this hole, without any difficulty, when the cylinder is upon the axis, this last is provided with a small tongue *k*, which goes exactly into the notch *f*, (fig. 43.) as is seen at *e*, (fig. 39.)

A pulley exactly like the former is fastened to the shoulder of this cylinder, by three similar screws, and in the same manner: observing equally here, that the outer surface of this pulley does not rub against its adjoining standard. This pulley is seen at *Q*, (fig. 1, Plate X.)

It is sometimes necessary to take this pulley and the cylinder off from the end *r* of the axis (fig. 39.) which is the reason why this cylinder is fastened by a screw, and not by a pin, like the other. They are taken off, to make room for putting upon the axis the cellular cylinder, which is of cast brass, and turned in a lathe.

Of the cellular Cylinder, Plate XII.

This cylinder is seen in profile, upon the axis, at *p*, *y*, *g*, *q*, *t*, *z*, (fig. 39.) and in perspective in fig. 44. Fig. 45, represents its longitudinal section. The part of this cylinder which is between the two lines *y* *t* and *p* *z*, (fig. 39.) is exactly like the above described cylinder, fig. 37 and 38, and *g*, *a*, *b*, *q*, (fig. 39.)

The only difference between them is, that the one is fixed permanently to the axis, by a pin *n*, (fig. 39.) and the other is fastened by a screw *v*, which passes through a female screw near the end of the cylinder, which is strengthened there for that purpose, by a moulding or collar *p* *z*. The end of this screw enters into a hole *m* in the axis (fig. 36.) but this hole is not a screw. The other part of the cellular cylinder included between the two lines *y* *t* and *g* *q*, (fig. 39.) is three inches and five-twelfths long; its outward diameter, throughout this length, is two inches and twenty-one twenty-fourths of an inch; and its inner diameter is two inches and a third. This inner diameter is a little wider towards the end *b* *c* of the cylinder, (fig. 44 and 45.) It is exactly the same as the outer diameter of the projecting part *c* *d* of fig. 37, which is to go into, and fit closely to the end *b* *c* of the cellular cylinder, (fig. 44.) so that the edge of this end *b* *c* may run quite up to the flat side of the shoulder of fig. 37. The pricked lines in fig. 45 and 38, are intended to express the correspondence of the parts of these two cylinders, which are to be united, by putting the end of one into the end of the other. Fig. 39 shows the cellular cylinder joined to the shoulder of the other cylinder: in which position it is that the cellular cylinder is fastened to the axis by the screw *v*, as before said: and that the end of this screw may be directed straight to the hole in the axis, whenever this cylinder is put on, two contiguous lines or marks may be made, one upon the edge *p* *z* of the cylinder, and the other upon the axis.

Of the Cavities of the cellular Cylinder, Plate XII.

On the surface of this cylinder, between the lines *y* *t*, and *g* *q* (fig. 39.) are scooped hollows or cavities, represented at large in fig. 47, N° 1. and seen in profile in fig. 47, N° 2. They are shaped nearly like a niche, which terminates in a cone at its top, and is rounded gradually deeper and deeper down to its bottom, which is a flat, perpendicular to the lowest part of the cavity.

To conceive and fix the position of these cavities upon the cylinder, the two pricked lines *i* *x*, *o* *s* (fig. 41.) must be drawn round the cylinder, at equal distances from the lines

y *t* and *g* *q*, and distant from each other two inches and one third, which is the inner breadth of the seed-box in which the cylinder is placed, as will be more particularly explained in the description of it.

The breadth between the lines *i* *x*, and *o* *s*, must then be divided into six equal spaces, by five other parallel lines drawn round the cylinder. Each of these spaces marks the width of each row of cavities; and these six rows of cavities must face exactly the six valves of the bin, which will soon be spoken of.

After this, the places must be marked for twelve similar cavities, placed at equal distances from each other, in each of the breadths traced round the cylinder; observing, that the length of the cavities is to be in the same direction as those breadths; and also, that the flat end of each cavity must be undermost, and the rounded end uppermost, when the cylinder fronts the fore-part of the drill, which is the view represented fig. 39; for it is the flat end of the cavities that is to go foremost, when the cylinder turns and drops the seed.

It is likewise to be observed, that each cavity should be opposite to the interval between two cavities in the next adjoining rows, as they are placed in fig. 39, 44, and 47.

It will be right to have two or three, or even more, cellular cylinders, equally fitted to the axis (fig. 39.) but with cavities of different sizes, in order to be thereby enabled either to sow more or less seed, or smaller or larger seeds, such as barley, lentils, pease, beans, millet, oats, &c. for each of which its proper cylinder should be used.

The cavities in fig. 47, N° 1 and 2, are of a size fit for wheat, barley, lentils; for millet, they must be much smaller; for pease, somewhat deeper; for oats, there should be but eight or nine cavities in each row, in order that those cavities may be made longer than for wheat, on account of the length of the oat, which is the only seed that I have found less easy to sow than wheat: the reasons are, the lightness of the oats, their not slipping easily between each other, and their having at one end of the grain a pretty long, flexible, and elastic point. These obstacles sometimes hinder the grains from entering into the cavities, and the seedman must be more careful when he sows oats, than when he sows any other kind of grain; though, notwithstanding these difficulties, I have had them sown pretty well.

To sow beans, the cylinder must have but three rows of cavities, of a length, breadth, and depth proportioned to the size of the beans. The bin, which has six valves for wheat, should have but three for beans, and these valves should be proportioned to the breadth of the cavities, which must be placed exactly opposite to them, as for wheat.

The following rule will determine the proper size of the cavities, by applying, as may easily be done, what is here said of wheat to any other kind of grain.

The cavities must be large enough to contain three or four grains of wheat, and their depth must be such that these grains do not rise above the surface of the cylinder, in order that when the cavities filled with seeds, pass under the valves of the bin, the grains may not fall out of the cavities. This will be still better understood, after reading the description of the seed-box.

Of the Seed-Box, Plate XII and XIII.

After unscrewing and taking off from the axis, the pulley *A* *B* (fig. 39.) its cylinder *b*, and the cellular cylinder *p* *z*, *g* *q*; the seed-box (fig. 48.) is placed upon the axis, by running the barred end of this last, through a round hole in each of the two parallel sides of the seed-box. The diameter of these holes is the same as that of the cellular cylinder, which is then to be put over the axis, by passing its proper end through the hole to the side of the seed-box, which it traverses, and fastening it in the manner before directed. The pulley is also then to be replaced. The front of this box is seen at *B* (fig. 1, Plate X.)

Fig. 49 represents the box and the cellular cylinder placed upon the axis, where it is to be observed that the outer breadth of the box, expressed by the interval between the lines *d* *e* and *k* *l*, is exactly the same as the length of the cylinder expressed in fig. 39, by the distance between the lines or shoulders *y* *t*, and *g* *q*; so that the box is held between these two shoulders *y* *t*, and *g* *q*. It is also to be observed, that the inner breadth of the box, expressed by the interval between the lines *f* *g*, and *h* *i*, in fig. 49, is exactly the

the three holes *a*, *b*, *c*, (these being female screws) in the flat part of the shoulder (fig. 41.) of the cylinder (fig. 40.) Each of these screws (fig. 42.) is from a quarter to a third part of an inch in diameter; and their head, which is flat, is about a quarter of an inch thick, and two-thirds of an inch in diameter. These heads are screwed into the holes *a*, *b* and *c*, till they lie even with the surface of the pulley on that side.

To the other end *b* of the axis (fig. 36.) is fitted exactly, though so as to slip on with ease, a third hollow cylinder (fig. 43.) of which the profile is seen at *b* (fig. 39.) It is like that which is marked *N d* at the other end of the axis; with this only difference, that the extreme diameter of the end *b e* of the cylinder (fig. 43.) is about two inches. This cylinder is fastened to the axis by a thumb-screw *e*, which goes through a female screw in the cylinder, and of which the end enters into the hole *l* in the axis (fig. 36.) which is not a female screw: and that the end of the screw may be directed to this hole, without any difficulty, when the cylinder is upon the axis, this last is provided with a small tongue *k*, which goes exactly into the notch *f*, (fig. 43.) as is seen at *e*, (fig. 39.)

A pulley exactly like the former is fastened to the shoulder of this cylinder, by three similar screws, and in the same manner: observing equally here, that the outer surface of this pulley does not rub against its adjoining standard. This pulley is seen at *Q*, (fig. 1, Plate X.)

It is sometimes necessary to take this pulley and the cylinder off from the end *r* of the axis (fig. 39.) which is the reason why this cylinder is fastened by a screw, and not by a pin, like the other. They are taken off, to make room for putting upon the axis the cellular cylinder, which is of cast brass, and turned in a lathe.

Of the cellular Cylinder, Plate XII.

This cylinder is seen in profile, upon the axis, at *p*, *y*, *g*, *q*, *t*, *z*, (fig. 39.) and in perspective in fig. 44. Fig. 45, represents its longitudinal section. The part of this cylinder which is between the two lines *y t* and *p z*, (fig. 39.) is exactly like the above described cylinder, fig. 37 and 38, and *g*, *a*, *b*, *q*, (fig. 39.)

The only difference between them is, that the one is fixed permanently to the axis, by a pin *n*, (fig. 39.) and the other is fastened by a screw *v*, which passes through a female screw near the end of the cylinder, which is strengthened there for that purpose, by a moulding or collar *p z*. The end of this screw enters into a hole *m* in the axis (fig. 36.) but this hole is not a screw. The other part of the cellular cylinder included between the two lines *y t* and *g q*, (fig. 39.) is three inches and five-twelfths long; its outward diameter, throughout this length, is two inches and twenty-one twenty-fourths of an inch; and its inner diameter is two inches and a third. This inner diameter is a little wider towards the end *b e* of the cylinder, (fig. 44 and 45.) It is exactly the same as the outer diameter of the projecting part *c d* of fig. 37, which is to go into, and fit closely to the end *b e* of the cellular cylinder, (fig. 44.) so that the edge of this end *b e* may run quite up to the flat side of the shoulder of fig. 37. The pricked lines in fig. 45 and 38, are intended to express the correspondence of the parts of these two cylinders, which are to be united, by putting the end of one into the end of the other. Fig. 39 shows the cellular cylinder joined to the shoulder of the other cylinder: in which position it is that the cellular cylinder is fastened to the axis by the screw *v*, as before said: and that the end of this screw may be directed straight to the hole in the axis, whenever this cylinder is put on, two contiguous lines or marks may be made, one upon the edge *p z* of the cylinder, and the other upon the axis.

Of the Cavities of the cellular Cylinder, Plate XII.

On the surface of this cylinder, between the lines *y t*, and *g q* (fig. 39.) are scooped hollows or cavities, represented at large in fig. 47, N° 1. and seen in profile in fig. 47, N° 2. They are shaped nearly like a niche, which terminates in a cone at its top, and is rounded gradually deeper and deeper down to its bottom, which is a flat, perpendicular to the lowest part of the cavity.

To conceive and fix the position of these cavities upon the cylinder, the two pricked lines *i s*, *o s* (fig. 41.) must be drawn round the cylinder, at equal distances from the lines

by *t* and *g q*, and distant from each other two inches and one third, which is the inner breadth of the seed-box in which the cylinder is placed, as will be more particularly explained in the description of it.

The breadth between the lines *i s*, and *o s*, must then be divided into six equal spaces, by five other parallel lines drawn round the cylinder. Each of these spaces marks the width of each row of cavities; and these six rows of cavities must face exactly the six valves of the bin, which will soon be spoken of.

After this, the places must be marked for twelve similar cavities, placed at equal distances from each other, in each of the breadths traced round the cylinder; observing, that the length of the cavities is to be in the same direction as those breadths; and also, that the flat end of each cavity must be undermost, and the rounded end uppermost, when the cylinder fronts the fore-part of the drill, which is the view represented fig. 39; for it is the flat end of the cavities that is to go foremost, when the cylinder turns and drops the feed.

It is likewise to be observed, that each cavity should be opposite to the interval between two cavities in the next adjoining rows, as they are placed in fig. 39, 44, and 47.

It will be right to have two or three, or even more, cellular cylinders, equally fitted to the axis (fig. 39.) but with cavities of different sizes, in order to be thereby enabled either to sow more or less seed, or smaller or larger seeds, such as barley, lentils, pease, beans, millet, oats, &c. for each of which its proper cylinder should be used.

The cavities in fig. 47, N° 1 and 2, are of a size fit for wheat, barley, lentils; for millet, they must be much smaller; for pease, somewhat deeper; for oats, there should be but eight or nine cavities in each row, in order that those cavities may be made longer than for wheat, on account of the length of the oat, which is the only seed that I have found less easy to sow than wheat: the reasons are, the lightness of the oats, their not slipping easily between each other, and their having at one end of the grain a pretty long, flexible, and elastic point. These obstacles sometimes hinder the grains from entering into the cavities, and the seedsman must be more careful when he sows oats, than when he sows any other kind of grain; though, notwithstanding these difficulties, I have had them sown pretty well.

To sow beans, the cylinder must have but three rows of cavities, of a length, breadth, and depth proportioned to the size of the beans. The bin, which has six valves for wheat, should have but three for beans, and these valves should be proportioned to the breadth of the cavities, which must be placed exactly opposite to them, as for wheat.

The following rule will determine the proper size of the cavities, by applying, as may easily be done, what is here said of wheat to any other kind of grain.

The cavities must be large enough to contain three or four grains of wheat, and their depth must be such that these grains do not rise above the surface of the cylinder, in order that when the cavities filled with seeds, pass under the valves of the bin, the grains may not fall out of the cavities. This will be still better understood, after reading the description of the seed-box.

Of the Seed-Box, Plate XII and XIII.

After unscrewing and taking off from the axis, the pulley *A B* (fig. 39.) its cylinder *b*, and the cellular cylinder *p z*, *g q*; the seed-box (fig. 48.) is placed upon the axis, by running the barred end of this last, through a round hole in each of the two parallel sides of the seed-box. The diameter of these holes is the same as that of the cellular cylinder, which is then to be put over the axis, by passing its proper end through the hole to the side of the seed-box, which it traverses, and fastening it in the manner before directed. The pulley is also then to be replaced. The front of this box is seen at *B* (fig. 1, Plate X.)

Fig. 49 represents the box and the cellular cylinder placed upon the axis, where it is to be observed that the outer breadth of the box, expressed by the interval between the lines *d e* and *k l*, is exactly the same as the length of the cylinder expressed in fig. 39, by the distance between the lines or shoulders *y t*, and *g q*; so that the box is held between these two shoulders *y t*, and *g q*. It is also to be observed, that the inner breadth of the box, expressed by the interval between the lines *f g*, and *b i*, in fig. 49, is exactly the

same as the length of the cylinder expressed by the lines $i x$, and $o s$, in fig. 39.

This brass-box has neither cover nor bottom, but is formed of four plates, each five twenty-fourths of an inch thick. Fig. 50 represents the inside of the plate F G, (fig. 48.) which is on the left-hand side of the drill, with the pieces which the box contains, and a section of the cylinder, lengthways of one of the rows of cavities. Fig. 51 represents the outside of the plate opposite to the former, and which consequently is on the right-hand side of the drill.

These two plates (fig. 50 and 51.) are exactly equal. Each of them forms a parallelogram, of which the length A B (fig. 50, and 51.) is four inches and eleven-twelfths, and the breadth B E four inches and fifteen-twenty-fourths. Both of them are perforated by a large round hole, of the same diameter as that part of the cylinder in which are the cavities. The center of this hole is in the middle of the breadth of these plates, and the upper extremity b , of this hole (fig. 50 and 51.) is an inch and one-sixth distant from the upper edge, D A, of the plate. Both the plates have four mortises, G, H, K, L; (fig. 51.) the breadth of which is equal to the thickness of the plates, and the length about half an inch; though this last is almost arbitrary. Both of them have also, directly facing each other, a hole at n (fig. 50, and 51.) three-twenty-fourths of an inch diameter, and of which the center is at the distance of five-twenty-fourths of an inch from the line D A, and half an inch from the line A B. The inner surface of both the plates is even; and lastly, each of them has, on its outer surface, a shoulder which projects round the rim of the great hole. One of these shoulders is seen in perspective in fig. 48. The profile of one of them is seen between the lines $d c$ and $f g$ (fig. 49.) and that of the other between the lines $b i$ and $k l$. Fig. 54 represents a section of them both. The thickness of this shoulder, that is to say, the distance to which it is to project, has already been determined by the total distance between the lines $y t$ and $g q$ (fig. 39.) When the inner surfaces of these two plates (fig. 50, and 51.) are laid against each other, their edges and holes, now described, should coincide exactly.

What they differ in is, first, that one of them (fig. 51. has a small opening M N, which the other has not, and which will be described in its proper place: and secondly, that the hole n (fig. 50 and 51.) is a female screw in fig. 50, to receive the end of a screw which traverses the box, but is not wormed in that manner in fig. 51, where the outside of the plate is hollowed a little around this hole, to make room for the flat head of this screw, which will be spoken of hereafter.

The two plates now described are fixed in their proper places by means of two others (fig. 55, and 56.) which last are of equal size with each other. D E (fig. 50.) is the profile of fig. 55, which is the back of the box; and A B (fig. 50.) is the profile of fig. 56, which is the front of the box represented at A (fig. 48 and 49.)

The two tenons A and B (fig. 55.) enter into the two mortises which are hid near G and H in fig. 50. The two other tenons C and D (fig. 55.) are expressed near G H in fig. 50, and receive the mortises G and H of fig. 51. In like manner the two tenons E and F of fig. 56, enter into the mortises hidden near K and L in fig. 50, where are marked the two other tenons, likewise seen at G and H in fig. 56, which are to receive the mortises K and L of fig. 51. The distance between the tenons of the same side of a plate, and consequently between their mortises, is arbitrary; as is also the length of the tenons, which are pierced, in order to their being fixed very tightly by pins about the twelfth part of an inch thick. These two plates (fig. 55 and 56.) when rightly placed between the other two plates, should be perpendicular to them, and parallel to each other, as well as to the lateral edges of those other plates, and the distance between them, from inside to inside, should be four inches. The upper edges of the four plates, when they are put together, should be horizontally level; by which means the bottom of the two largest plates will reach lower down than the smaller. These two smaller plates (fig. 55, and 56.) are shaped like a parallelogram two inches and a third wide, and four inches and thirteen twenty-fourths long. This breadth answers exactly to the space between the lines $i x$ and $o s$, (fig. 39.) and between the lines $f g$ and $b i$, (fig. 49.)

The plate (fig. 55.) which is seen in perspective in fig. 52, has, quite across its inner surface, a solid plint $x L$, which is of the same piece as the plate, and runs parallel

to $f g$, (fig. 52, and 55.) The bottom of this plint is flat, and its top is arched like a portion of a circle. Its thickness from i to n is nine twenty-fourths of an inch, and its projecture $i x$, (fig. 5.) is such that its edge $x L$ meets the surface of the cellular cylinder, as in the profile d (fig. 50.)

The use of this plint is to strengthen the assemblage of the plates; for which purpose its ends $x L$, (fig. 52.) should join exactly to the larger plates: and it serves likewise to prevent the grains of corn from slipping down between the plate and the cellular cylinder.

To the top of the inside of this plate is fastened, by two screws a and p (fig. 52.) a plate of brass, one-twelfth of an inch thick. Its extent, $a p$, $d b$, is a rectangle parallelogram, of which the breadth $a p$, or $d b$, is the same as that of the plate to which it is fastened; so that its edges $a b$ and $p d$ lie close to the insides of the two largest plates (fig. 50 and 51.) The profile of this plate is seen at $a l b$, (fig. 50.) where it is inclined from l to b , in such manner that the whole length of its edge $b d$, (fig. 52.) is almost close to the surface of the cylinder, directly above its axis, as in the profile b , (fig. 50.) But this plate must not quite touch the cylinder, because it would then obstruct its motion, or at least occasion a needless and detrimental friction. Its use is to hinder the corn which fills the space F, from falling down into the space M, and to make it pass only under the piece $r q$ (which will soon be described) to drop from thence into three pipes, which begin near e , as will be seen hereafter.

The plate fig. 56, (seen in perspective in fig. 53, with some pieces fixed to it) has, rising upon its inner surface, four exactly similar small partitions, which are of a piece with the plate. These four partitions $c p$, $d e$, $f g$, $b i$, (fig. 56.) are seen in perspective at $m s$, $o t$, $q v$, and $r x$, in fig. 53. The top $r x$ of all these partitions is rounded like the quarter part of a circle, and the bottom $x v$ is flat, and at the same height as the axis of the cylinder, as may be seen in the profile e of one of these partitions (fig. 50.) The two outer partitions $c p$ and $b i$, (fig. 56) are at the edges of the plate, and the two others $d e$, $f g$, divide the space between c and b into three equal parts. These partitions are about a twelfth part of an inch in thickness, and their rounded part terminates in an edge, that the grains which may chance to fall upon it may not lodge there. The height $u r$, (fig. 53.) or $i b$, (fig. 56.) of all these partitions, is nine twenty-fourths of an inch. The lower ends $s w$, $t o$, $v a$, $x u$, (fig. 53.) of all these partitions, are in a plane perpendicular to the plate, and parallel to the edges $b a$, $q r$, of this plate (fig. 56.)

This plate has also upon its outer surface a small cylinder, which is seen in profile at K, (fig. 50.) in front at A, (fig. 49.) and in perspective A, (fig. 49) and B, (fig. 1. Plate X.) Its whole length is two-thirds of an inch, and its diameter is half inch excepting its shoulder at the plate, which is a little more.

This cylinder is pierced lengthways with a female screw, which goes through the plate perpendicularly to its surface, and through which passes a screw C q, (fig. 50.) five twenty-fourths of an inch in diameter, of which the end is seen at q , and the head at C. This head is also seen at B, (fig. 1. Plate X.) The hole is seen at k (fig. 56.) in the inner surface of the plate. The center of this hole k is in the middle of the breadth of the plate, and at the distance of five twenty-fourths of an inch from its edge $a b$. This fixes the place of the screw and of its cylinder; the only use of which last is, by its length, to give the greater stability and firmness to the screw, which keeps the bin at a greater or less distance from the cellular cylinder.

Of the Bin and its Valves, Plate XIII.

The bin, which has six valves, is seen in profile at $q n$, (fig. 50.) The outside of this bin is seen in perspective at $g h n$, (fig. 53.) with the ends of the valves a , b , c , d , e , f , separated from each other by partitions. It is suspended in the box by the axis or screw before mentioned (fig. 50, and 51.) which goes in at the hole n in the end (fig. 51.) of the box, then passes through the hole n of the bin (fig. 50, and 53.) runs quite through the length of the bin, and screws into the female screw in the plate (fig. 50.) which, as was said before, is directly opposite to the hole n in the plate (fig. 51.) The head of this screw, at n (fig. 51.) lies even with the outer surface of this plate.

Fig. 57, represents in perspective the bin alone and its parti-

partitions, all made of one piece, or plate of brass. Fig. 58, represents geometrically the fore-part of the bin, which is here turned towards the seedman. Fig. 60 represents its back. Fig. 62 its bottom. Fig. 59 one of its utmost sides, or largest partitions, both of which are equal and alike. And fig. 61 the side or profile of one of the smaller partitions; which are all equal and like to each other.

The whole length of the bin from outside to outside, that is to say, from a to c , and from b to d , (fig. 58.) or from c to d , and from e to f , (fig. 60.) is the same as the breadth of the inside of the box, or of the space between the lines $i x$ and $o s$, (fig. 39.) or $f g$ and $h i$, (fig. 49.) The bottom of the bin is a parallelogram i, k, d, b , (fig. 58.) or $a b d c$ (fig. 60.) eleven twenty-fourths of an inch wide at $a c$ and $b d$. This bottom is of the same thickness as the largest partitions or sides $a b, c d$, (fig. 58.) and the five smaller partitions; that is to say, three twenty-fourths of an inch. These partitions, both great and small, are at equal distances from each other, and all their sides are perpendicular to the bottom of the bin.

The whole length of the two largest partitions, (fig. 59.) from b , to the pricked line $g d$, which is perpendicular to $a b$, is one inch and seventeen twenty-fourths. Their breadth at $a i$ and $b c$ is five-ninths of an inch. The line $c m$, parallel to $b a$, is eleven twenty-fourths of an inch long. The notch $l m$ is one-twelfth of an inch deep. The angle a, b, c , is of eighty-five degrees. The perpendicular distance from the center of the hole s , to the line $g d$, is a quarter of an inch; and the perpendicular distance from the same center to the line $a b$, is five-twelfths of an inch. The diameter of this hole is a full twelfth of an inch. The perpendicular distance from the center of the hole r , to the line $g d$, is very near, but not quite, one-sixth part of an inch; and the perpendicular distance from this same center to the line $a b$, is five twenty-fourths of an inch. The diameter of this hole is one-sixth of an inch. These two main partitions, $a b$ and $c d$, (fig. 58.) which have now been described in the account of fig. 59, are exactly alike, and pierced in the same manner; so that if they could be laid flat together, inside to inside, their dimensions and holes would tally perfectly.

It is through the hole r , (fig. 59.) that the screw or axis is passed which keeps the bin suspended to the plates, and which was mentioned before. These two holes $r r$ are seen in fig. 57, where their axis is indicated by two prick-lines. And it is through the hole s , (fig. 59.) that the screw or axis is passed which goes through the valves, next to be spoken of, and by which they are suspended in the bin. These two holes $s s$ are seen in fig. 57, with their axis, which is indicated by two pricked lines.

Fig. 61, represents the profile of the small partitions. Its total height from $a b$ to $c d$, is equal to the breadth $d b$ of the bottom (fig. 60.) as is shewn in fig. 58. The shape and size of these small partitions is exactly alike, and equal to that part of fig. 59, which is included between the lines e, f, b, c ; so that their edges would tally in all respects, if they were laid one upon the other. The line $c d$, (fig. 61.) is perpendicular to $c a$.

The edge $m c$, (fig. 59.) is a bevil, sloped towards the inside of the bin, as at $e f$, (fig. 57.) and $a d$, (fig. 62.) The like edge $z b$, (fig. 57.) and $b f$, (fig. 62.) is sloped in the same manner. All the similar edges $e b$, (fig. 61.) of the small partitions, which are included between the lines $e f$ and $b d$, (fig. 58.) are bevils on each side, and form as many acute edges, as is seen in fig. 62, between the lines $a b$ and $d f$. The distance between the lines $a b$ and $g b$, is five-ninths of an inch.

Fig. 58, is repeated in fig. 64, with only the addition of the six springs $a b, c d, e f, g h, i k, l m$, each of which is fastened by a small screw, a, c, e, g, i, k , at one of their ends, next to the bottom of the bin, and in the middle of the interval between two partitions. The breadth of these springs is nearly equal to two-thirds of this interval, and their thickness is the same as that of a common spring of a watch, which is the stuff they are made of. Fig. 63, exhibits a front view of one of these springs. Their length and bending, when in a state of rest, is represented in the profile $e d$, (fig. 65.) $b a$ (fig. 66.) the profile of these springs in a state of contraction.

Fig. 64, is represented in fig. 67, with only the addition of the six valves $c d, e f, g h, i k, l m, n o$, seen in profile in fig. 65 and 66. Each of these six valves is, at most, one-

twelfth of an inch thick, and their total length, $a b$, (fig. 65.) is one inch and thirteen twenty-fourths. The six valves, put together, weigh twenty penny-weights, or five-sixths of an ounce. When put into their proper places (fig. 67.) each of them covers one of the before-mentioned springs. The breadth of each of them is equal to the whole width of the interval between two partitions; between which they must only be able to move. They are all fastened to the same axis, $a b$, which, as was said before, passes through the holes $s s$, (fig. 57 and 50.) The diameter of this axis is a full twelfth part of an inch. One of its ends screws at a , (fig. 67.) into one of the aforesaid holes s , and the other end, which has a flat head, is buried at b ; in the other hole s ; for which purpose the outside of the plate is pared away a little, around this hole. One of these holes is seen at p , in fig. 50 and 53. The valves are laid flat in fig. 67, with their springs contracted, as in the profile (fig. 66.) When the springs are at liberty, they push the valves out of the partitions, as far as is represented in the profile (fig. 65.) But they are kept within partitions, by a cover $a b$, (fig. 69.) which is put into the notch $f m$, (fig. 59.) and $c d$, (fig. 60.); and, in short, into all the notches, which are upon a level with each other, from $i e$ to $f k$, (fig. 58.)

Fig. 67, is repeated in fig. 69, with only the addition of the cover, which is three quarters of an inch wide; as long as the whole breadth of the bin, and not quite a twelfth part of an inch thick. It is fastened by two screws a and b , which go into the upper edge of the large partitions, as appears in the profile (fig. 66 and 70.) Fig. 70 represents one of the large partitions of the bin, with the end $e d$ of its cover, and the head of one of the screws which fasten it. Fig. 66, represents the profile of one of the small partitions of a valve $e f$, of its spring $a b$, and of the cover $d c$. This figure shews also, that the end of the valve closes with the lowest edge of the partitions; as may be seen more distinctly at $d o$, (fig. 67 and 69.)

Fig. 68, represents the back of these six valves fastened to their axis.

The end of each valve, d, f, h, k, m, o , (fig. 67.) is bent a little outward; as in fig. 71, which is only a repetition of fig. 62, with the addition of the springs of the valves, and their cover.

The whole bin, furnished with the six valves and their axis, the six springs and their screws, and the cover and its two screws, but not the axis or screw which suspends the bin in the box, weighs four ounces and a half.

The bin thus completed, and suspended in the box, as was said before in speaking in fig. 50 and 53, is again covered by a thin plate of brass represented in perspective at i, A, k, N, P , (fig. 53.) and of which the profile is likewise seen at i, A, s, k , (fig. 50.) This plate is bent at $A P$, (fig. 53.) in such manner that its bended part turns inward, over the upper edge of the front of the brass-box; and its edge, which is seen in profile at $A i$, (fig. 50 and 53.) and fully at $e n$, (fig. 48 and 39.) is fastened to the upper part of the outer surface of this plate of the box, by two screws c and n , which go into the holes l and m , in fig. 56. This plate, from its bending $A P$, (fig. 53.) projects over into the box, inclining down to the bin, which it covers as low as $N k$, where the cover of the bin before mentioned ends. This plate performs the office of a spring, and should therefore be screwed on very tight. It presses the bin against the end q of the setew $q C$, (fig. 50.) The breadth $A P$ and $k N$ of this plate, (fig. 53.) is the same as the breadth of the inside of the box; so that its two edges, $A k$ and $P N$, lie close to the inner surfaces of the two large plates, (fig. 50 and 51.) which form the ends of the box.

Of the three Pipes of the Seed-Box, Plate XII. and XIII.

Fig. 72, represents a perspective view of the three pipes, which are seen partly at B, D, E , fig. 48 and 49, Plate XII. and at $a b$, fig. 1, Plate X. They are made of plates of brass, about a twelfth part of an inch thick, and are separated from each other only by a simple partition. Their front is seen in perspective, and on the right hand side of the drill, in fig. 72. Their back is shewn in perspective, and on the right hand side of the drill, in fig. 53. Their front is represented geometrically in fig. 49 and 73; and their back in fig. 75. Fig. 74, represents geometrically, the side or profile of the middle pipe, which is inclined with

the piece that fastens it to the plate. The profile of the pipes on each side of this is indicated by pricked lines.

These three pipes, (fig. 72.) are set against the plate (fig. 56.) in such manner that the edges a, b, c, d , (fig. 72.) are applied close to it, and in the same order, at i, r, v, g , fig. 56. The edges g, h, f, e , (fig. 72.) are applied in like manner at p, q, s, e , (fig. 56.) The line b, h , (fig. 72.) is set exactly even with r, q , (fig. 56.) By this means the anterior surfaces b, c, k, i , and f, h, l, m , of the two outer pipes, (fig. 72.) exceed the bottom of the box, as at B, D , (fig. 48 and 49;) and the upper edges a, n, d, o, e, p, g, q , (fig. 72.) join to the lower edges of the four partitions (fig. 56.) as i, g, e, p , as is seen in perspective in fig. 53, at x, u, v, a, t, e , and s, w .

These three pipes, which hold together, are fastened to the plate by means of a single brass scutcheon A , (fig. 72.) which is seen directly in front at H , (fig. 49.) and at A , (fig. 73.) Its fore-part and right hand side are seen in perspective at A in fig. 72; and its fore part and left-hand side at H (fig. 48.) fig. 75 shews a full view of the back part of it at A ; and the whole profile of it on the right-hand side, is seen at N, u, B, L , (fig. 50.) and at b, d, l, f , (fig. 74.) This scutcheon is bent at d and at m . Its breadth is the same as that of the middle pipe, which is the interval between the other two, as is seen in fig. 48, 49, 72, 73, 75. Its part b, d , (fig. 74.) is foldered or riveted to the lower surface of the middle pipe: from thence it takes an horizontal direction from d to m , and then ascends perpendicularly from m to f . This length m, d is one inch, and the thickness of the scutcheon, throughout, as about a sixth part of an inch, or somewhat less. The thickness of the plate, fig. 56, of which the profile is here at q, l , fig. 74, is exactly embraced between the extremity r, i of the pipe, and the scutcheon f, l . The bottom q, r , (fig. 56.) of this plate, rests upon the horizontal part o, l of the scutcheon, (fig. 74;) and this scutcheon is fastened to the plate by a screw p, g , which goes into the hole n , (fig. 56.) It is to be observed, that the line r, o , (fig. 74.) is equal to the edges a, b, c, d, e, f, g, h , (fig. 72.) of which it expresses the profile; that its farther extent o, a , (fig. 74.) is equal with lines q, i, c, k, f, l, b, m , (fig. 72.) of which it expresses the profile: and that the line d, l , (fig. 74.) is in the same horizontal plane as the line b, h , (fig. 72.)

The angle r, i, e , (fig. 74.) is of one hundred and twenty-six degrees; and the distance from o to i is one third of an inch. The outside breadth of these three pipes, taken together, is the same as that of the plate; and each of them occupies a third part of that space, as in fig. 53, 46, 73 and 75. Each of them is square. The length of the two outer pipes, from the line b, h , (fig. 72.) or from the bottom q, r , of the plate, (fig. 56.) to the line i, m , (fig. 72.) or x, o , (fig. 56.) is one inch and a twelfth: the length of the middle pipe, (fig. 74.) from i , where it joins to the plate, to its other end e , is four inches and five twelfths.

These three pipes are fastened to the plate, as in fig. 53. The edges $x, z, v, T, E, t, l, D, s, y$, of their upper openings, are circular, that they may fit exactly, and fit close to the circumference of the cylinder, which is there indicated by pricked lines, and is shewn in fig. 50, by the line t, v, f , which expresses the profile of these edges, against which the cylinder rubs lightly when it turns.

Manner of working the Seed-box, and of the Pieces which it contains, Plate XIII.

The line or edge g, h of the six valves, (fig. 53.) must be very near to the surface of the cellular cylinder, through not quite so close as to occasion a friction when the cylinder turns; and the lower end of each valve must answer to a row of cavities; so that the part F of the seed-box, (fig. 50.) being filled with corn, and the cylinder turning from b to r , this last carries with it the grains that fall into the cavities which pass under the edge of the corresponding valves: those that fall from the two valves a and b , (fig. 53.) are dropped, by the cavities, into the pipe G , in the space between the pricked lines g, s and b, t , and are conveyed to the back of the share which is on the left hand side of the drill: those that fall from the two next valves, c and d , are dropped between the pricked lines b, t and d, v , into the pipe H , and are conveyed to the back of the share which is in the middle of the drill: and those that fall from the two last valves, e and f , are dropped between the pricked lines d, v and b, x , into the pipe M , and are conveyed to the back of the share which is on the right side of the drill.

If it happens that several grains press together at the same time, at the outlet of any one of the valves, so as to choak it, that valve immediately gives way, lets them pass, and is instantly replaced as before, by means of its spring which pushes it back. No grain is ever broken by the valves: so that if this accident does sometimes happen to a few, it is not during the time of actually sowing the seed, but only when the drill is turned, in order to begin another bout, or when the seedsmen, instead of drawing the drill forward, drags it towards himself, and makes the cylinder turn backward.

By loosening the screw C, q , (fig. 50.) which is at B in fig. 1, the bin, before pressed against this screw by the spring or plate A, s, k , (fig. 50.) is moved farther from the cylinder, the space between the cylinder and the end of the valves is increased, and a greater quantity of corn then passes at a time. By turning the screw C, q farther in, the bin is pushed nearer to the cylinder, and fewer seeds are dropped.

To know exactly how much the bin should, at any time, be set nearer to, or farther from the cylinder, there is, at one of the sides of the bin, a small screw, of which the head of m passes through a circular opening M, N , (fig. 51.) in the largest plate of the box, where it becomes a certain guide, by means of a few equal divisions engraved and numbered at the edge of that opening. The center of the arch of this opening is the same as that of the hole n , upon which the bin moves.

Of the Hopper, Plate XIII.

Fig. 67, represents in perspective the hopper which is seen at A in fig. 1, and of which the bottom covers the top of the seed-box. D , (fig. 76.) is the front, and A the right-hand end of the hopper. The boards which form the ends A and B are three quarters of an inch thick; those of the sides D and C are seven-twelfths of an inch thick; and the thickness of the cover is five-twelfths of an inch. The sides and ends, which are at right angles to each other, and to the bottom, are joined together by dove-tail tenons; and the bottom is joined to the ends A and B by tenons which go into mortises in these ends, as may be seen on the line b, g . The four tenons G, H, E, F , enter into the mortises Q, R, S, T , in fig. 24, of which the dimensions have been given. Those dimensions fix the length g, e , or k, d , of the hopper (fig. 76.)

Its breadth from outside to outside, at a, k , or b, g , is seven inches; and its outside depth k, g , or d, e , is eight inches and a half. The height of the legs of the hopper, from the line b, l , where it rests upon the upper surface of the table, to the line b, g , which is the under surface of its bottom, is determined by the distance between the top of the seed-box and the top of the table: it is here eight inches and a sixth. In the middle of the breadth of the two legs, are two openings, N and P , rounded at their top, to let through them the iron axis which bears the cellular cylinder, and keeps the seed-box steady under the hopper. These two openings are seven inches high, and one inch and three quarters wide. The hopper is fastened to the table by two hooks, one of which is seen entire at L, N, M , and part of the other at P, Q . Each of them moves upon the rivet L , just above the opening of the foot, and is bent from thence to N to make room for the passage of the axis; after which it hooks into a ring M and Q , fixed upon the table, but not mentioned before.

Towards D is a square opening, an inch and a half wide, cut immediately above the bottom, and through which the hopper may be emptied. This opening is shut by a small plate of iron or brass, which turns like a latch upon a screw n , which fastens it at that end, whilst the other end r is slipped down to the small piece of brass or iron v, x , which is fastened to the box by a screw at x , in such manner, that the pricked part of the latch, near r , is covered by the end v of this last small piece, which is bent for that purpose, so as not to lie quite close to the box, and the edge r, q of the farther part of the latch rests upon the edge x of this small piece.

Of the Fore-Carriage, Plate XIV.

Fig. 77, is a perspective view of the fore-carriage without its wheels. It is seen with its wheels in fig. 1, Plate X. Fig. 80 represents a geometrical plan of the inside of one of the wheels of the fore-carriage, which is seen at t fig. 1, Plate X. and fig. 81, Plate XIV. represents a section of it. P and Q (fig. 77.) are the two fore ends of the beams, to

to which the fore-carriage is fastened by hooks and rings.

In fig. 77, *a d*, and *D E*, are the two exactly similar pieces which are seen at *S s* and *V r* in fig. 1. Their length *a d*, (fig. 77.) is two feet eight inches; their breadth *d A*, is two inches and two thirds, and their thickness is two inches. They are parallel to each other, and connected by two traverses, *g, h, f, l*, of which the ends are tenons pinned into mortises in the pieces *D E, a d*. These two traverses are omitted in fig. 1, Plate X. in order to render that drawing the more simple. The length of these traverses, exclusive of their tenons, is two feet, their breadth is two inches and a quarter, and their thickness one inch. These two traverses are perpendicular to the two other pieces. Their distance from each other, between the farthest outside edge *g h* of the one fig. 77, and the farthest outside edge *f l* of the other, is seven inches and a half. The edge *g h* is one foot six inches and a third distant from the two ends *B* and *D*.

F G is an axle-tree, of which the middle part *n s* is two inches and seven-twelfths square, and of which the upper angles are cut off as in the drawing. The square shoulders of the two ends *s n*, from whence the spindles proceed, project a very little beyond the outside of the pieces *D E*, and *a d*, in order that the nave of the wheels may not rub against these pieces. The spindles *s G, n F*, are eight inches and a third long, and one inch and five-twelfths in diameter. This axle-tree is placed upon the pieces *D E, a d*, parallel to the traverses *g, h, f, l*, in such manner that the distance from the lines *s n* to the ends *E* and *A*, is a foot and a half. This axle tree is fastened to the two pieces *D E, a d*, by two iron pins and nuts, *b q*, an inch and a sixth square, of which the screw, which is seven-twelfths of an inch in diameter, has a head an inch and a half in diameter, which lies close to the under surface. This screw is represented with its nut in fig. 68. Upon this axle-tree are fixed two wooden pins, five or six inches long, and five-tenths of an inch, or a whole inch in diameter. These pins are perpendicular upon the upper surface of the axle-tree; the space between them is four inches, and this space is in the middle of the length of the axle-tree. This axle-tree is pierced perpendicularly between the two pins, to admit another pin, which will soon be spoken of.

The two wheels, which are placed at *F* and *G*, are exactly alike. Fig. 80, represents the inside of one of these wheels, with a pulley fixed round its nave, and fastened to its spokes by four screws, each of which goes through the pulley and one of the spokes. This pulley is seen in profile at *b d*, (fig. 81.) with two of its screws.

The total diameter, *g h*, of each wheel, exclusive of its iron hoop, is two feet and a half; that of the nave *p q* is four inches and one sixth; that of the pulley *b d* is one foot two inches and a sixth; the thickness of the pulley is an inch and one third; its groove, which is cut down square, is two thirds of an inch wide, and two thirds of three quarters of an inch deep. The length *p r*, or *q s* of the nave, is six inches; the thickness of the wheel at *i n* is an inch and two thirds, and at *i b* two inches and a quarter. Of the four hooks *R, H, T, K*, (fig. 77.) which serve, by means of two rings, to fasten fore-carriage to the ends of the beams *P Q*, the two, *H* and *K*, are fastened in the usual way, by nailing them, at their flat end, upon the two pieces of the fore-carriage: but the other two, *R* and *T*, are shaped like a carpenter's square of which one end is screwed upon the beam, in order to facilitate the putting on or taking off the ring. At *T*, this hook is placed in its proper situation for holding the ring: at *R*, it is turned the other way, that the ring may be taken off easily.

Of the Pieces which support the Drill upon its Fore-carriage Plate XIV.

Fig. 82, represents in perspective a piece of wood which supports the drill upon its fore-carriage, when there is occasion to turn it in sowing. This piece may be called the pole. It is seen at *x x d* in fig. 1, Plate X. Its end *A*, (fig. 82.) enters into the two bridles or belts *g r b* and *a c b*, (fig. 26.) which have been spoken of before, and of which one is seen near *d* in fig. 1. Its other end *q r*, (fig. 82.) rests upon the axle-tree (fig. 77) between the two pins, as is expressed by pricked lines in fig. 82, and as may be seen at *x* in fig. 1.

The breadth *q r*, (fig. 82.) of the lower surface of this piece is an inch and a quarter, throughout its whole length, to its end *A*; and its thickness throughout its whole length *q s* is an inch and a half. Its upper angles are taken off from the end *q r* to *s*; but from *s* to *A*, this piece is shaped like the two bridles or belts into which it is to enter.

Its length from *q* to *s* is one foot seven inches and five sixths; and from *s* to *t*, it is two inches and seven-twelfths. At *t*, the thickness of a quarter of an inch is taken off from its under surface, as at *t v*; and from *v* to *A*, its length is five inches and five-twelfths. It is the length *s A*, that goes into the two belts or bridles *g r b*, and *a c b*, (fig. 26, Plate XI.) and the notch or shoulder *t* is made in order to insert a wedge whenever it is necessary to make the end *q r*, (fig. 82.) rest upon the middle of the axle-tree, in order to convey the drill the more easily to any distant part, without putting it upon its hind-carriage. This wedge saves the seedsmen the trouble of holding up the handles of the drill so high as he would otherwise be obliged to do, to make the end *q r* of this piece (fig. 82.) rest upon the axle-tree. It is by a help of this piece, that the seedsmen, when he comes to the end of each bout of the drill, is enabled very easily to turn it in order to begin another, by lifting the drill up by its handles; for as the end of this piece rests upon the middle of the axle-tree, he makes the drill follow the fore-carriage, which is drawn by a horse; and as the distance, in this case, is but five or six feet, there is no occasion for his making use of the wedge. By this means the drill is turned conveniently, and without any loss of time.

The lines *A v, t, s* are even: but *q s* is inclined at *t s*, and makes with it an angle *t s q* of 166 degrees. *s a* and *g n* are two square pins, fastened by tenons into the middle of the breadth of the under surface *r q s*, perpendicularly to the lower surface *t s*. The pin *s a* is placed near the bending *s*, and the distance between the edges or lines *s a* and *g n*, is fourteen inches and two thirds. The breadth *a o* and *n p* of these pins, is an inch and a quarter: their thickness is two thirds of an inch; the length of *s a* is three inches and a half, and that of *g n* five inches. This pin *g n* is rested against the axle-tree *F G* of fig. 77; and the other, *s a*, (fig. 82.) is placed near the table of the drill. The use of these two pins is only to hinder this piece of wood from slipping out of the two belts before described.

Fig. 83, represents in perspective the piece of wood which supports the drill upon its fore-carriage, when it is placed upon its hind-carriage, in order to be removed from one place to another. This piece neither is, nor can be, seen in fig. 1, which represents the drill in the state of actual sowing, and without its hind-carriage. The end *A*, (fig. 83.) goes into the belts *e f, g h*, (fig. 21.) before described, like which it is shaped; and the end *B*, (fig. 83.) rests upon the axle-tree, (fig. 77.) between the two pins. This part of the axle-tree is covered before and beneath by a slip or hook of iron *B E C*, (fig. 83.) which is nailed under the end of the piece *A B*, as in fig. 84. The axle-tree, the bar, and its hook, are traversed by an iron pin, *D E*, (fig. 83.) and *d e* (fig. 84.) which passes through the hole in the axle-tree, between the two pins, (fig. 77.) The length of this piece, *A B*, (fig. 83) is three feet and four inches: its breadth is two inches and a half, and its thickness is one inch and a third. The pin *F G*, which is suspended here, is put into the ring or bridle *L*, (fig. 22.) and goes through the hole immediately underneath it.

Of the Hind-Carriage.

This hind-carriage is so simple that it would be needless to give a drawing of it. It consists only of two common wheels, unshod with iron, two feet eight or nine inches in diameter, set upon a very simple axle-tree, in the upper surface of which are two holes, into which are put the two pins before-mentioned, which are under the beams of the drill. One of them is seen at *f b*, (fig. 3) and likewise at *Δ*, (fig. 1.) Plate X.

It is necessary to fix, by proper marks, the respective places of the several screws and mortises of the whole machine, in order that when it is taken to pieces and put together again, none of these pieces may be misplaced, or any of the helixes (or spiral lines) which the flat-headed screws have formed in the wood, be spoiled.

It is better to make the teeth of the harrow bend a little more

more than those before described; and represented in fig. 5, Plate X. They should bend so that the point *e* of the tooth may project about four inches beyond the pricked line *f*.

Figures 85 and 86, Plate XIV. compared with Figures 2 and 31, Plate X. and XII.

The mortise A, in fig. 85, is the same as that which is marked Q in fig. 2. But the end of each beam should be made about two inches wider on the inside, and a second mortise B, (fig. 85.) should be cut through it, similar and parallel to the former, and at the distance of five-sixths of an inch, or an inch from it, that the share may be fastened in the one or the other, according as it may be found proper to place the two fore-shares nearer to, or farther from each other, in order to sow the rows closer than they would be by the situation of the mortises Q and R, (fig. 2.) but then the pipes which answer to the back of these two shares should be fastened in the manner which will be explained hereafter.

The middle piece K L, (fig. 2.) should project beyond the table, from C to D, (fig. 85.) about nine inches or a foot, and the belt or bridle L, (fig. 2.) should be suppressed. This same piece should have, in its parts E F, (fig. 85.) nearly the same breadth as the end of the beams H, I; and two mortises, E, F, instead of one, in which the share, thicker than was said before in its upper part, is to be fastened by two tenons and a key. The pipe which terminates behind this share, instead of passing sideways, as in fig. 31, will go straighter and more easily through the hole G, (fig. 85.) which is seen at K, (fig. 86.) and from thence through the thickness of the share, which will be pierced for this purpose from K to G. The sole of this share, from this hole to its bottom, will be of the same thickness as was mentioned before.

Figures 87 and 88, Plate XIV. compared with Figures 29 and 30, Plate XI.

The upper opening, *f d, h o*, (fig. 29.) of the two foremost pipes should be joined by a good hinge A, (fig. 87.) well soldered to them, and of which the pin, ending with a ring at one end, may easily be taken out. By means of this hinge, these two pipes may be set closer together or farther asunder, like the legs of a compass, and be fitted to the different situations of their shares. The fastening of the lower end of these pipes will be nearly the same as was described in fig. 30; with this difference, that instead of bending the square *k i g* of that figure only at *i*, upon its upper surface, and making its part *k i* run lengthways of the beam E F; here fig. 88 is twisted as it were in the bending, in order that the part *s n* may lie across this beam, and lengthways of the table. In this case, if the share A be put into the mortise B, the parts *s n* must be slipped farther, till the hole *s* can be fastened at *n*, by the thumb-screw which is at *n*: and as this part, being held only by a single screw, might be apt to loosen and jog, a piece or slip of iron, *a v*, is permanently fixed at its edge, so as to keep it tight in either of its situations. The screw *n* fastens in a nut sunk into the upper surface of the beam, where this nut is permanently fixed, and covered by the table. There should likewise be two holes in the other part of the square, towards *q*, to serve for the two different situations of the share. The pipes of the shares are more easily made round, as is here represented, than square, as was directed before.

Figure 89, Plate XIV. compared with Figure 35, Plate XI.

Instead of the small groove *n*, (fig. 35.) in the brass cylinder, intended for introducing a little oil to that part, a more simple way will be to bore a perpendicular hole *p*, (fig. 89.) through the head of the standard, down to the spindle; and this hole may be covered by a small plate A, made to turn upon a screw or rivet.

Figures 90, 91, 92, 93, and 94, Plate XIV. compared with Figures 50, and 53, Plate XIII.

As the three pipes or funnels, G, H, M, (fig. 53.) embrace at their upper opening only a small part, *f, t*, (fig. 30.) of the cellular cylinder, some grains may chance to be lost on the side where this cylinder is not covered from *d* to *f*. To prevent this inconvenience, they may be made

so as to embrace the whole lower semi-diameter *d f t*; of the cylinder in the manner represented in fig. 90, 91, 92, 93, 94.

The first funnel, which is seen geometrically at A, B B, (fig. 90.) is represented in perspective, and of a small size, in fig. 93; where its corresponding parts are marked with the same letters, *a, b b*. This is the funnel M of fig. 53. The second large funnel; of which a part appears at D, (fig. 90.) is seen entire and in perspective, in fig. 92, where the same part is marked *d*. This is the funnel H of fig. 53. Two scutcheons *g* and *p* are soldered to this funnel, and fasten it, by screws, to the fore and hind inner surfaces of the box, as at P, G, (fig. 90.) The third funnel, which does not appear in fig. 90, and which is like the first, is represented in fig. 91. This is the funnel G of fig. 53. These three funnels are made separately, of very thin plates of brass, bent, and well soldered; and are afterwards firmly riveted to each other, side to side, as in the perspective, (fig. 94.) They are so tightly joined, that the scutcheons *g p*, (fig. 92 and 93.) are alone sufficient to hold them all in their proper places.

Figures 95 and 96, Plate XVI. compared with Figures 66, Plate XIII.

In the representation of this part in fig. 66, the valve *e f* is actually closed by its spring *a b*, to the cover *d c*, and in this situation it is shut: but when the corn presses against this valve, and forces it into the situation *a b*, (fig. 95.) a grain may jump so as to get between the valve and the cover, and thereby hinder the valve from closing again; so that more corn would continue to run out. To guard against this accident, each valve must have a small tongue *p* immediately below the cover, and the cover must be bent in that place, to receive the tongue when the valves close. Both of these are represented separately in perspective, in fig. 96.

Fig. 97, Plate XIV. compared with Figures 50 and 51, Plate XIII.

Instead of the index *m*, (fig. 50.) and the graduated opening M N, (fig. 51.) an easier and more simple way will be, to fasten the end A of a graduated limb or border of a circle, A B, (fig. 97.) to the bin, in such a manner that its other end B may project through a hole in the front of the brass box. This will mark exactly the situation of the bin.

Figure 98, compared with the Figures 82, 85, Plate XIV. 21, 26, Plate XI.

When the middle piece is lengthened, as at C D, (fig. 85.) there is no occasion for the ring or bridle L, (fig. 2.) and *f k*, (fig. 26.) or for the pieces *s a* and *g n*, (fig. 82.) and then the pole A, of this fig. 82, will pass through the belt A, (fig. 98.) and through another belt B, which last goes round it and the piece D. This belt is fixed by two screws under the piece B D. The pin C, which penetrates into the table, will complete the fixing of this pole. The hole K, (fig. 85.) receives the pin F G (fig. 83.) which goes through the two pieces C D, (fig. 85.) and A B (fig. 83.)

M. de Chateauxvieux's Instructions concerning the Manner of using his DRILL PLOUGH.

This drill is represented in fig. 1, Plate X. with all its parts put together, in a state fit for working. When the thongs which encompass the grooves of the pulleys Q P of the axis in fig. 1, and those of the fore-carriage *u t*, are stretched properly, and the hopper is filled with corn, a horse is to be harnessed to the spring-tree bar, and an intelligent man, who can walk a good pace, should guide this horse, which should be a mild tractable creature.

"The seedsmen will hold the handles of the drill, in order to direct it: and he will warn the guide whenever he deviates from the straight line in which he ought carefully to keep. He will also observe from time to time whether the distribution of the seed is not stopped by some unexpected accident; for he can see the end of the pipes through which the grain should drop; besides which, the corn makes a little noise in passing through the pipes, and he may easily hear it. The seedsmen will take particular care that the

the thongs do not slip out of the grooves of the pullies; and if they do, he will replace them instantly: but this accident is very rare; nor, indeed, does it hardly ever happen, unless the thongs are new, and have not yet been sufficiently stretched. It is proper to observe here, that we have tried hempen ropes, and small iron chains; but thongs of leather are much better than any other thing.

"Care should be taken that the seed-corn be free from grit, dirt, or little stones; for either of these might damage the valves of the bin. If the corn has been steeped in lime-water, as is the practice of some farmers, in hopes of preserving their crops from smut, it must not be sown till it is so dry that the grains will slip easily over one another.

"The seedsmen will be particularly careful to replenish the hopper before it is quite empty.

"He will oil the spindles of the axis once or twice a day; observing, that they require most frequent oiling when the drill works in dry ground, which sends up a very fine dust: and he must cleanse the spindles and the pipes in which they turn, every morning, by rubbing off the old oil, and putting on new. He will also, from time to time, cleanse the spindles of the axle-tree of the fore-carriage, and rub them with soap. If any rain happens to fall during the time of sowing, he must wipe the drill very dry, as soon as he has got it home, and particularly about the axis, to prevent its rusting. It is even highly proper to have a leather covering to put over the table and all the parts upon it, and likewise over the standards, the axis, and the hopper. It is easy to conceive the proper cut of this covering.

"The prudent husbandman should always have with his drill, a small box, containing a hammer, a pair of pincers, a turn-screw, thongs, ropes, nails, iron rings and buckles, a little bottle of oil, and other such like things, in order that, if any of them should be wanted in the field, he may not lose time by being obliged to send home for them.

"The seedsmen will observe, when he is going to sow, not to leave the wedge *t*, (fig. 24, Plate XI.) under the pole, in order that the end *c*, (fig. 1, Plate X.) may not press upon the axle-tree of the fore-carriage. The only use of the pole, at the time of sowing, is to turn the drill when a second bed is to be sown after the first is finished, and so of others. It is easy to conceive, that if this end of the pole should make the drill rest upon the axle-tree, it might often happen, that, by its being thereby too much subjected to the motions of the fore-carriage, the stones or clods which the wheels may meet with, would, by raising them higher than the general surface, throw the shares out of the ground, or at least occasion the furrows to be shallower in those places, things which ought by all means to be avoided.

"We have represented but one spring-tree bar, in fig. 1, because we think a single horse may be used, without any inconvenience, when the ground is not too much loaded with wet: but if the land be too full of water, two horses must be put to the drill, which, in that case, must have a double bar, the manner of ordering which is too well known to need any description. Each horse will then go in a furrow, and they will not poach the bed, as would be the case in wet land, if the drill was drawn by only one horse, whose steps are determined by the middle of the bed.

"For want of horses, oxen may be used, and the sowing may be performed equally well.

"It is proper to observe, that the quantity of seed distributed by the drill is exactly the same, whether the horses or oxen go fast or slow. If, for example, one bed is sown in ten minutes, and twelve or fifteen minutes are employed to sow another, of equal dimensions, neither more or less seed will be dropped in one than in the other; because the revolutions of the cylinder, (fig. 39.) are invariably regulated by those of the wheels of the fore-carriage, whose circumference, be it turned quick or slow, will always describe a line of equal length, and the cylinder turns exactly with these wheels. The only difference that can arise from the greater or less speed of the horse, is the gain or loss of time: but the quantity of seed sown will be constantly the same, so long as the drill remains set in the same manner.

"The greater or less goodness of the soil, its having been well or ill prepared for sowing, its state of dryness or humidity, and several other circumstances which should be carefully attended to, will oblige the husbandman sometimes to vary the quantity of seed. The drill is accordingly made to distribute more or less, by the means before-mentioned,

of placing the bin nearer to, or farther from the cellular cylinder, by turning the screw *L*, (fig. 50, Plate XIII.) By setting the bin farther off, a greater quantity of seed is dropped; and by bringing it nearer, a less proportion is sown. It will be easy to find the proper distance at which to fix it, in order to its giving out exactly the desired quantity of seed.

"Though this method affords a pretty wide latitude, it may sometimes not be sufficient. This is a case which will very seldom happen, and which we have not yet met with; but if it should any time take place, the drill may easily be made to distribute still more or less seed, by changing the pullies of the axis, (fig. 39, Plate XII.) for others of a larger or smaller diameter, which will either accelerate or retard the motion of the axis, in proportion to their size.

"We will suppose, for example, that the pullies are but of half the diameter of those before described. It is evident that these smaller pullies will make the axis turn round twice, where it turned but once with the former, and that double the quantity of seed will consequently be dropped on the same length of ground. By the same rule, pullies twice as large, will turn the axis but half the number of times, and but half the quantity of seed will of course be let fall in the same space. The proportion of the seed sown may likewise be increased or diminished by a greater or less number of cavities in the cellular cylinder; and the changing of this cylinder is soon and easily performed: but, as was said before, there will very seldom be any occasion for these alterations.

"The furrows opened by the shares of the drill, and in which the seeds are deposited, should be of different depths, in different cases; and this may be effected by means of the rings which fasten the drill to its fore-carriage at the hooks *R H*, *T K*, (fig. 77, Plate XIV.) For general use, the diameter of about three inches, from inside to inside, will be sufficient for these rings, and then the furrows are made about three or four inches deep. They will be opened deeper by using rings, about four inches in diameter; and it is immaterial whether they are round or oval. With smaller rings, the furrows will be made shallower; and their depth may also be diminished, by making the horse draw with longer traces, or by using a lower horse.

"If very shallow furrows are wanted, or only just the surface of the ground is intended to be opened, the wedge *t*, (fig. 24.) must be put under the pole. In short, a little practice will soon shew the husbandman how to manage this drill in every respect, and make him thoroughly acquainted with all that is necessary to be known in regard to the distribution and proper covering of the seed, which last part is perfectly well performed by the teeth of the annexed harrow.

"If any thing should still seem obscure to those who have read attentively, and studied the description of each part of this drill, let them but set actually to work, and their ideas of it will soon be perfectly clear. Each part taken separately, may be made with great ease: their sizes, shapes, and proportions, are pointed out in such manner, that no workman of common understanding can mistake; and when the parts are constructed, there can be no difficulty in putting them together, if the foregoing directions are but observed.

Description of a Harness to yoke Oxen one before another, Plate XIV.

"The utility of being able to put oxen to this drill, in such manner as to make them go one before another in the furrow, without treading upon the places which are to receive the seed, first put me upon contriving a harness proper for these cattle: for I was not satisfied with those I had seen in different countries. Two of my teams of oxen, harnessed in my new manner, have worked the whole year; several persons have adopted the method; and I am more and more pleased with it. The harness is very simple, and very light, and does not subject the oxen to any irksome confinement.

"Fig. 99 and 100, represent the whole of this harness, that is to say, its plan and a view of it. Fig. 99 shews it to be composed of a yoke *A*, which the ox bears upon his head, and which is there fastened to his horns by long thongs. The rest of the harness is of leather. The piece *B*, is the principal part, and that by which the ox is to draw

draw. It rests against his neck, a little below the withers, and sits extremely close to the neck when the ox draws. If it is made of double leather, there is no occasion for the piece of leather D, which serves only to strengthen it when it is single. The thong C fastens in the buckle Q R, which is fixed to the yoke by another thong. The use of these is to hinder the large piece of leather B, from rising above the withers, when the ox tosses his head, or raises his neck. Care should be taken not to stretch the thong C too much, for the ox must not draw by it.

"The thong E E, with their buckles to lengthen or shorten them, serve to make the oxen draw by the yoke, by putting them through the large iron buckles F F, and the leather buckles G G, which must be nailed to the yoke. The length of these thongs is suited to the purpose for which they are intended.

"My traces are made of ropes, and I find them convenient. At one end of them is part of a leathern trace, about fifteen inches long, like the end of the harness of a coach horse. This end is put through the large buckles F F, where it is fastened by the tongue a a: so that the trace may easily be shortened or lengthened."

The best sort of harness for oxen, is the same that is used for horses. In this manner, the oxen are enabled to exert their strength to much more advantage, than in yokes, and bows, as has been proved by experience; and that two oxen can, in harness, perform as much work as three of the same strength in yokes. They are not so speedy as horses, and therefore not so proper for harrowing, and other business that requires a quick motion: but for a hard steady draught, and in harness, will do their work as well as horses, allowing them some more time.

DRILL-RAKE, an instrument invented by M. Vandusfel, for drilling pease, &c.

This instrument is chiefly calculated for light grounds, in small inclosures, not exceeding four or five acres. It is a sort of strong plough-rake, with four large teeth at a a, b b, (Plate XV. fig. 1.) a little incurvated, as represented in the figure. The distance from a to a, and b to b, is nine inches. The space, or interval, between the two inner teeth, a and b, is three feet six inches, which is sufficient room for the cultivator or hoe-plough to move in, if conducted with care, before the pease have branched much. To the piece of timber c c, forming the head of the rake, are fixed the handles d, and the beam e, to which the horse is fastened.

It is evident, that when this instrument is drawn over a piece of land made thoroughly fine, and the man who holds it bears upon the handles more or less according to his discretion, four channels or small furrows f, g, h, i, will be formed; that the distance between the furrows h i, and f g, will be nine inches: and that the interval e, or space contained between the furrows g, h, will be three feet and a half. It is also evident, that these distances may be preserved with great truth, provided the teeth a, a, return (when the ploughman comes back, after having ploughed one turn, or a bout, as they call it) in two of the channels formed before, marked b b; so that though he cuts four drills at the first bout, yet, in effect, he only forms two drills each turn, because there are always two drills to be passed over twice, or re-ploughed, being, in fact, not much more than guides, or marks of directions. Yet even this small work of supererogation repays itself, because it makes the drills more open, distinct, and clear.

If the first four channels, formed at one motion by this instrument, are straight and true, all the lines in the field will partake of the same regularity. It will therefore be proper to mark out this first trace of the drill-rake by exact measurement, fixing into the ground, at every distance of ten feet, little flat sticks, labelled with paper; which being finished, the rest may be left to the ploughman.

When the ground-plot of an acre is thus formed into drills (which may be completed in four hours, by one ploughman, a horse, and a boy to lead the horse) you must send two or three women and children into the field in order to sprain the pease, or scatter them by a single motion of the hands; at a certain distance one from another, into the channels. Use no harrow, which will be apt to draw the seeds out of the lines; but cover them with the flat part of the head of a hand-rake, and press them down gently.

The great excellence of this drill-rake consists in its simplicity; for after the measurement of the parts is once

laid down, the meanest carpenter and smith in England can either make or repair it; and if the first four inches formed by it are true, the rest of the lines or rows must be geometrically exact, which is an elegance none can feel, but such as take delight in correct husbandry. *Essays in Husbandry, Essay II. p. 212.*

DRILL-ROLLER. The late lord Orford put in many acres of barley, pease, &c. with a machine not long invented in Norfolk, which has done much work so well, that many have been made, and are highly approved. It is a roller about seven feet long, around which are cutting wheels of cast iron, that turn round each independently of the others, around one common cylinder, weighing about a ton. It is drawn by four horses; the cutting wheels being moveable, may be fixed at any distance, by means of washers; but the most common and favourite distance is four inches. I enquired, but in vain, for the inventor of this machine: it was improved by a Mr. Sillis, at Hertford Bridges, near Norwich.

The mode of working it is this: a layer being ploughed which the owner intends for setting or dibbling, this roller is used to save the expence. It is drawn across the furrows, and cuts the whole field into little drills, four inches asunder; the seed is then sown broad-cast in the common quantity, and the land bush-harrowed; by which means the seed is deposited at one equal depth, as in drilling; that depth a better one than in setting, and the crop rises free from the furrow-seams, which are the ill effects of common broad-cast sowing on a lay, ploughed once. Lord Orford's crops, sown with this roller, I viewed with great pleasure: they are perfectly regular, and of a beautiful appearance. This machine promises to banish dibbling. *Young's Annals, vol. XII.*

DRINKING CISTERN. In his Rural Economy of the Midland Counties, Mr. Marshall makes the following observation:

"In an open yard, belonging to one of the first managers of the district, I saw a drinking-cistern on an admirable plan. It is formed by a watertight wall, raised high enough above ground, to prevent the cattle from stepping into it, and low enough to let them drink freely. The brick-work, which forms a cistern about four feet square, is guarded by a post at each corner, with rails passing from post to post, over which rails the cattle drink. It is fed by a covered pipe (of pipe bricks) reaching to a large drinking-pool, at some distance from the yard; so that while this is full (which it is in winter) the cistern is so likewise to the brim. If it overflow, (which it generally does at that season) a waste-water pipe conveys the surplus out of the yard.

"Cisterns of this kind, when they can be formed at an easy expence, are much preferable to pits, in farm-yards."

DRINKING-POOLS. Mr. Marshall, in his Rural Economy of Norfolk, says, "In this country there are three species of artificial drinking-places:

- "Standing pools,
- "Artificial rills,
- "Field wells.

"**STANDING POOLS**, or the art of pond-making, ranks among the most useful arts in Rural Economy. In many high situations, no other expedient can be practised with propriety: rills cannot be raised, nor wells sunk and worked, but at too great an expence for the purpose of watering stock.

"On the hills of Surry and Kent, ponds are made to hold water tolerably well with chalk beaten firmly together.

"Experiments have, it is said, been tried with chalk upon the Yorkshire Wolds without success; owing, probably, to the too great hardness of the Wold-chalk. A soft chalk is no doubt fittest for this purpose.

"In Norfolk, I apprehend, they have been formerly made with marl. In all countries where unfathomed beds of clay are common, drinking-pools sufficiently retentive, may, at a small expence and without much art, be formed, and are in general sufficiently abundant.

"But the art of making retentive pools with clay, in loose absorbent soils, is a recent discovery which has been hit upon in this district; in which it has made a rapid progress, and is now in universal practice among farmers of every class. Indeed, for a country like this, where upland soil is kept principally in grass, it may well be considered as the most valuable discovery which has lately been made in rural economy.

"Francis and Robert Gardiner, well-diggers and fish-pond makers, of Driffeld, are entitled to much more than the credit of this discovery. The York Agriculture Society voted them a premium of ten pounds: were the nation to grant them ten thousand, it would not be more than they merit."

DRONE, the male bee, one that makes no honey. See the article **BEES**.

DROPSY, a disease incident to horses, and generally called the water-farcy. See **WATER-FARCY**.

DROPWORT, the name of a perennial weed common in pasture lands, having winged leaves; the divisions of which are all regular, and sharply indented about the edges. The flowers are white, growing in a bunch like an umbel. Its roots are very remarkable, consisting of a bunch of knobs hanging upon threads: from whence it has the name of filipendula, and dropwort. The flowers have an agreeable smell.

DROUGHT, dry weather, want of rain. It also signifies thirst, or want of drink.

DUB, a pool, or pond of water.

DUCK, the name of a well-known fowl, very necessary for the husbandman's yard, as they require no charge in keeping; for they live on lost corn, snails, &c. for which reason they are very proper for gardens. Once in the year they lay a great number of eggs, especially a sort of duck which turns up its bill more than the common kind. When they sit, they require no attendance except they have a little barley or offal corn near them, that they may not straggle far from their nests to chill their eggs. They are reckoned to be better hatched under a hen than a duck; because while they are young, the hen will not lead them so often into the water. Some reckon it very proper to cut off the feathers from their rumps; because when their tails are wet, it often occasions their drowning. As to the fattening of them, you may do it in three weeks time, by giving them any kind of corn or grain, and plenty of water. Ground malt, wet either with milk or water, is best. *Mortimer's Husbandry*, vol. I. p. 257.

DUN, a colour partaking of brown and black.

DUNG, the excrements of animals, putrefied vegetables, &c. used in improving land.

Dungs are intended either to repair the decay of exhausted worn-out lands, or to cure the defects of other soils, which are as various in their qualities, as the dungs used to meliorate or restore them. Some lands are too cold, moist, and heavy; whilst others are too light and dry. To answer this, some dungs are hot and light, as that of horses, sheep, pigeons, &c. Others again are fat and cooling, as that of oxen, cows, hogs, &c. And as the remedies which are used, must be contrary to the distempers they are to cure, so the dung of oxen, cows, and hogs, should be applied to lean, dry, light earths, to make them fatter and closer; and hot and dry dungs to cold, moist, and heavy lands.

Dung has two peculiar properties. The one is to fatten the earth, and render it more fruitful; and the other, to produce a certain sensible heat, capable of causing some considerable effect; which last is seldom found but in the dung of horses and mules, while it is newly made, and a little moist.

Horse-dung, the least fat of any, is the most fiery, if taken fresh as it falls, and the most apt to excite a sudden fermentation; for which reason it is then fit only for the hot-bed. When this heat is past, it may be spread on fields where we would have a rank grass to spring: but it should not by any means be admitted into the garden, or where we would wish to have good roots, unless the ground be very stiff, cold, or wet, and then too it should be well rotted, lest instead of correcting the soil, it leaves couch, and other pernicious weeds, worse than the disease itself; the seeds of hay, and of other plants, which horses eat, coming oftentimes entire from them: for those vegetables which cattle chiefly eat, commonly spring up from their dung; as long knot grass from this beast; short, clean, and sweet pasture from sheep and cows; the sow-thistle from swine. Ground mucked with horse-dung is always the most infected of any; and if it be not perfectly consumed, it makes your roots grow forked, fills them with worms, and gives them an unpleasant relish: but if laid on at the beginning of winter, and turned in at spring, it succeeds sometimes with pulse.

Horse-dung is greatly improved by being mixed with its opposite, cow-dung, which is cold and fat; and this mix-

ture is considerably meliorated if mixed with a proper earth, with mud, or with ashes and urine. Cow-dung alone is the worst of all dungs to endure wet, because it is the most easily dissolved. But either of these dungs, either singly, or mixed as above, should not be used till it is old; nor should it be laid abroad, exposed to the sun and wind, as is the practice of several injudicious farmers, who let it lie spread on their field-lands during three or four of the summer months, till the sun and air have exhausted all its virtue: whereas, if it be laid in heaps, mixed with earth, and left in that state till it be rotten, it will be the sooner brought to a proper temper, will produce a sweeter grass when laid on pasture grounds, and will go much farther than in the common way when spread before the plough for corn, of which it will then greatly promote the growth.

Mr. Miller says he has frequently seen new horse-dung buried as it came from the stable in very cold, moist land, and always observed that the crops have succeeded better than where the ground was dressed with very rotten dung.

Sheeps-dung and deers dung are nearly of the same quality, and are generally esteemed the best of all dungs for cold clays. Some recommend beating them into powder, and spreading them very thin over autumn or spring crops, about four or five bushels to an acre, in the same manner as ashes, malt-dust, &c. are strewed. But this light dressing does not last long. The most common way of conveying it upon the land is by folding of the sheep themselves upon it, by which means their urine is saved as well as their dung, which ought to be turned in with the plough as soon as possible, that it may not lie exposed to the heat of the sun. In Northamptonshire, they think it best to fold sheep after July, and to fold them the latest upon dry land. In some parts of France, where they likewise fold their cows and oxen, the place of folding is changed twice every night. In Flanders, they house their sheep at night in places spread with clean sand, about five or six inches thick, which being laid on fresh every night, is cleared out once a week. This mixture of sand and dung makes an excellent dressing for strong land; for the dung and urine of the sheep is a very rich manure. M. Quintinie thinks it the greatest promoter of fruitfulness in all sorts of ground. This method of folding sheep in a covered fold, and of mixing their dung with earth, sand, &c. according to the nature of the soil it is intended for, is likewise, very properly recommended by Mr. Mortimer; who adds, that he has known vast crops of rye upon barren lands that have been old warrens, well dunged by rabbits; and large oak and ash upon the same, though the soil was very shallow.

Next to sheeps-dung, the preference is generally given to that of swine, one load of which will go as far as two loads of other dung. The laying it on too thick may perhaps have occasioned the old mistaken notion of its breeding more weeds than any other dung: for all dungs will make weeds shoot up: whether they contain within themselves seeds of those plants, not so thoroughly digested by the animal as to be deprived of their vegetative power, as may sometimes be the case, or by the additional fertility which they communicate to the earth. This dung is best when carried from the sty directly to the field, where it is a rich manure both for corn and grass, especially the latter, and for almost any sort of land. Hot sands and gravel are particularly benefited by it; and it is reckoned a very great fertiliser of fruit-trees. Many good husbandmen prefer this dung before most ordinary sorts of manure, and to take great care not only to have their hog-yards well paved and paved with pebble, or other stones, or with chalk, which is much the best; but also to increase the quantity of the dung as much as they can, by throwing into the sty all the straw, fruit, roots, beans, plants, weeds, &c. which are the refuse of the garden, with the offals of the kitchen, and every kind of trash; all which is not only very good for the hogs, themselves, but increases their dung to such a degree, that ten or twelve swine have yielded sixty or eighty loads of excellent manure in a year. Some notable farmers will make their hog yard produce them an annual profit of twenty or thirty pounds. Mr. Worlidge thinks this the best of dungs to prevent or cure the canker in trees; and Mr. Mortimer esteems it best for manure, when mixed with horse-dung: for which reason he advises placing the hog-sty as near the horse dung-hill as can conveniently be. The farmers in Staffordshire frequently sow on poor light shallow land, a small white pea, which they never reap, but turn in as many hogs as they think the crop will fatten, and let them lie upon it day and night. The dung

and urine of these animals enrich the land so much, that it soon acquires a thick sward, and continues to be good grazing ground for several years.

In this light, of reaping a double advantage from the manuring of land, the author of the new System of Agriculture advises husbandmen to sow ten or fifteen acres of their ground with turnip-feed, a little before they sow clover, which he thinks is best done in September: then, towards the beginning of March, to take the best opportunity to buy three hundred sows, all such as will farrow in about a month. Let little sties, formed of boughs and reeds, be made for them in the most convenient parts of the clover ground, either in the corners, or under the hedges of these fields; and let the sows be kept up, and fed daily with the turnips which were sowed the autumn before. At first, it will be necessary to take the trouble of boiling them, tops and all, and of giving them in the troughs with the water not yet cold: they may afterwards be only scalded; and in a week or ten days the swine will eat them raw, with the greatest greediness and pleasure. In the beginning, or towards the middle of April, these sows will farrow: after which they must not be fed with turnips any longer than till the clover is pretty high, when they and their pigs may be turned in among it. It is impossible for one who had not seen it, to imagine how eagerly the swine will graze on clover, which increases their milk to such a degree, that the pigs shoot forward at a double rate, and as they leave off sucking, they too take to feeding on the clover, by which they prosper so fast, that by the end of October, every pig will fetch twenty or five and twenty shillings, in any market. The treading of great cattle is apt to break the stalk of clover grass, and they spoil, by trampling it down, a much greater quantity than they eat; but swine are never hurtful this way; and if there be any fear of their rooting up the ground, that may be easily prevented by a ring in their noses; though our author says, he never knew a hog break up an inch of clover. They graze upon it with more pleasure than they could root.

Human ordure is a very fat and hot manure, full of fertilizing salts, and therefore extremely proper for all cold four soils, especially if it be mixed with other dung, straw, or earth, to give it a fermentation, and render it convenient for carriage. Some do not like to use it on account of its bad smell; and others imagine that it gives a fetid taste to plants; but in this they seem to carry their delicacy rather too far. It is used with great success in many parts of France, all over Flanders, and, I believe, not less profitably round about London. Mr. Bradley says, it is kept in pits, made on purpose, in foreign countries, till it be one, two, three, or four years old: that of four years old is accounted the best; that of three years tolerable; but the others not so fit for use; and that the persons concerned in these pits pay great regard to the place from whence they have it, preferring that which comes from towns where the most flesh is eaten, as the strongest and richest manure. It certainly should not be laid on too new, nor in too great quantities, because it is of a very hot nature, but when that heat is tempered by age, putrefaction, and a due mixture with other soils, it becomes a rich and excellent manure. Perhaps it may owe great part of this richness to the urine with which it is mixed; for though human urine be destructive to vegetables, whilst it is new, by reason of its burning sal-ammoniacal spirit, as Glauber terms it, yet, as in many other moist things, subject to putrefaction, time will correct that defect, digest the urine, take off its fiery quality, and so alter its nature, as to render it an extraordinary fertiliser of every kind of soil. Columella certifies, that old urine is excellent for the roots of trees. Mr. Hartlib commends the Dutch for preserving the urine of cows as carefully as they do the dung, to enrich their lands, and instances a woman he knew near Canterbury, who saved, in a pail, all the urine she could; and when the pail was full, sprinkled it on her meadow, the grass of which looked yellow at first, but afterwards grew surprisingly. Similar to this is what Mr. Bradley relates, as of his own knowledge. Human urine was thrown into a little pit constantly every day, for three or four years. Two years after some earth was taken out of this pit, and mixed with twice as much other earth, to fill up a hollow place in a grass walk. The turf which was laid upon this spot, grew so largely and vigorously, besides being much greener than the rest, that by the best computation he could make, its grass, in a month's time, was above four times as much in quantity as that of any other

spot of the same size, though the whole walk was laid on very rich ground. The author of the English Improver is therefore very right in saying, that human urine is of great worth, and will fatten land more than is generally imagined by our farmers, whom he advises to take all opportunities of preserving this, and every sort of urine for their ground, as carefully as is done in Holland.

The dung of all poultry is of a very hot nature, full of volatile salts, and therefore extremely proper for cold lands, being light of carriage, and a little of it going a great way. It is most commonly used for distant grounds, where it is sprinkled on wheat or barley, after they are come up, or upon the latter at the time of sowing. Mr. Mortimer thinks forty bushels sufficient for an acre. It is used to most advantage when dried and powdered, and is very efficacious in keeping frost out of the earth. Its effects are sudden, but they do not last long. Hens dung is very rich, though not so hot as pigeons dung, nor is it so easy to sow, because it hangs more together, neither can it be so easily collected. The opinion that goose dung is rather hurtful than beneficial to corn or grass, is an ancient error, as is proved by Mr. Worlidge, who says, he was credibly informed that a flock of geese having made a track across a field of wheat during the winter, and nibbed the corn clear from the ground in their daily passage in such a manner, that the wheat upon it proved the next year much finer than any other part of the field. He also mentioned a field which had been given to the town of Sutton in Northamptonshire, for feeding geese, whose dung rendered it one of the richest pastures he ever saw, inasmuch that all sorts of cattle fed on it very greedily; nor could we hear from any of the inhabitants, that so much as one beast received the least injury from it. He adds, that his own horses, kept in a piece of pasture on which geese lay very much, eat the grass barest where the fowls had dunged most, and that he never found it do them any hurt, except making them too fat.

Perhaps the reason why the dung of geese has been said to occasion barrenness, flowed from observations where it had been laid too thick; for being of a hot fiery nature, it will, if laid on in too large quantities, destroy the grass; but if spread thin in the winter, it will prove a very rich and valuable manure, especially if mixed with cooling earth, and left for some time to putrefy.

DUNG-HILLS, heaps of dung collected in the yard, and other places, belonging to a farm.

They are made up of the dung of different animals, of different kinds of straw, and other vegetable substances; and they have frequently different animal substances in their compositions. See MANURE.

Compost, or compound dunghills, are a collection of different matters, as earth, mixed with dung from an ordinary dunghill, lime, and other manure.

Some persons make dung-hills of this kind, and are of opinion, that the dung and other manures with which they are compounded, are thereby made to enrich a greater quantity of land, than if not mixed with earth; and besides, do not produce the bad effects which sometimes are produced by dung, when taken directly from a dung-hill, and laid upon land.

It will not be amiss that we enquire into the advantages of this kind of dunghill, which will be a means not only of recommending them, but also of pointing out the most proper method of constructing them.

The first thing to be enquired into, is the advantage arising from the mixing lime, marle, or other manures, with the earth and dung. Lime, as it is a dissolver of all vegetable and animal substances, when mixed with dung, will help to dissolve it; and as it communicates an absorbent power to earth, will enable the earth with which it is mixed to attract the vegetable food in greater plenty from the air. But in order to make it produce these effects, it is necessary to mix it with dung and earth: for if the lime is laid in a kind of stratum above the dung, and below the earth, it will absorb the water that falls upon the dung-hill, and thereby will prevent the dung from receiving a sufficient quantity of water to make it putrefy; and will also occasion such a heat as to burn the dung, and render it useless; and besides, can have but little influence in dissolving the dung, and communicating to the earth its absorbent quality. If the lime is laid above the earth and exposed to the air, it will be attended with the same consequences: it will absorb the water; and though it will attract the vegetable food from the air, yet will be of no more use for this end, than if spread upon

as much land as the surface of the dung-hill extends to.

The same thing may be said of marle, if used instead of lime; but if marle is used instead of earth, it is probable that the compost will become very rich; as the marle has a very strong absorbent quality; and would be greatly exposed to the influence of the air. A much smaller quantity than is used in the ordinary way, it is probable, would be found sufficient, and its effects would be sooner discovered. If this is tried, it will be necessary to carry the dung to the marle-pit, and there form the dung-hill; for marle is so heavy a body; that it would be too expensive to carry it first to the dung-hill; and then to the field.

The advantage of mixing dung with the earth is next to be considered. This, it is probable, is the principal advantage of the compound dung-hills, and that the advantages arising from lime are but trifling. They are often made without lime, and their effects, it is said, are equally good.

Dung, in the ordinary dung-hills, has its vegetable food sometimes washed away by rain, when it falls in large quantities. Now this is prevented by the earth in the compound dung-hill, which absorbs the water, and all the vegetable food which it carries from the dung.

It is very bad management to suffer the water which falls immediately upon dung, to drain from it wastefully; but infamous, to suffer that which is extraneous to drain through it; though the latter is too frequently the practice.

In the ordinary dung-hills, the dung on the surface, it is generally supposed, loses a part of its vegetable food, which is exhaled by the sun, or carried off by the wind. This is prevented by covering the dung with earth in the compound dung-hill.

But it is probable, that the compound dung-hill receives its principal advantage from the earth being exposed to the influence of the air; and if this be true, the more absorbent that the earth is which is used, and the larger that the surface of the dung-hill is, in proportion to its bulk, and the quantity of dung contained, it will be the richer.

This directs us to the proper method of constructing it, to make it long and narrow, with as many divisions in it as can be made conveniently; for thereby a larger surface is exposed in the same quantity, and the more vegetable food acquired.

Mr. Marshall recommends dung-hills to be made not less than 14, nor more than 18 feet wide, as this size will admit room for two men behind, and one on each side. If it is narrower, the men at the wheels have not sufficient employment; if it is wider they have too much, nor can they reach the cart without moving their feet; and making a step takes up as much time as throwing in a shovel-full of compost. The sides of a dung-hill should not be upright, nor too high, that the men may stand on the steps to fill. Perhaps one rod wide, and a quarter of a rod high, when settled, is the best form of a dunghill.

It is proper to observe further, that earth should always be in the bottom of the dung-hill, to receive any of the juices of the dung which the rain may carry downward; that the dung should be immediately covered with earth, to prevent the juices from being exhaled, or carried off; and that the earth should be exposed for a considerable time, before any more dung is laid on, that so it may receive all the benefit from the air which it is capable of, before it is covered.

This kind of dung-hills is made with least expence upon the field for which the dung is intended. The head-ridges are commonly high raised, by the turning of the ploughs upon them, and contain the richest earth in the field. These are very proper places for the dung-hills. The earth is at hand, and can easily be thrown upon the dung.

Those that treat of dung-hills of this kind, commonly recommend earth as opposite as possible to the nature of the soil upon which the dung is to be laid. They recommend clay for a light soil, and light earth for a clay soil. But these the farmer cannot always command; and though he can, will frequently find it very expensive to carry them. It is probable, that there is not so much in adapting the earth of the dung-hill to the kind of soil, as persons at first sight are apt to imagine. It is certain that there cannot be so much in it as to answer the expence of fetching the earth. It is true, that in many farms, there are different soils, and therefore the dung may be carried to a soil different from the soil of the field for which it is intended; there

the dunghill may be formed, and from thence carried to the field; but still this is an additional trouble and expence; and therefore this method is not to be followed, till, upon a comparative trial, the advantages are found to do more than answer the expence.

It is a practice in some parts of Scotland to lay clay upon clay land. This practice, it is said, succeeds very well, which makes it probable that it is not very material what kind of earth is used for the compound dung-hill, provided it is of the absorbent kind; and, therefore, the farmer need not be anxious about getting earth different from his soil, but may make his compound dung-hill of the earth of the field which he intends to manure.

Dung, and other manures are very important articles in farming: but though they are universally used, the manner of their operation upon land, whereby it acquires a greater degree of fertility, is but imperfectly known. It is, however, generally agreed, that they ferment in the soil, whereby it is opened and pulverised. Manures are of different qualities, which adapt them to different sorts of land; but by mixing them together, as in composts, they are correctives of each other, and by that means become a more general manure, than any one of them can be singly; and their jarring qualities seems to be a means of prolonging their fermentation in the earth, which is one of the acknowledged benefits of manure.

In regard to mixing and preparing composts, it is frequently recommended, and commonly practised by farmers, to place the several materials in layers, six or eight inches, and sometimes a foot thick: but when they are laid so thick, especially clay, or strong earths, the fermentation in the compost is seldom strong enough to penetrate such thick layers of strong close earth: and if it does not when the compost heap is turned, these layers come out whole as laid in; they receive but little benefit by the fermentation, and require almost as much labour to break and mix them as they would have done at first. It is therefore much the best way to break the strong earth and other materials at first, and to employ several labourers to throw them upon the compost heap in such manner as to mix them well at first. By this method a fermentation quickly commences, the whole is intimately mixed and incorporated; so that much less turning than common is necessary, and the compost is ready for use in a much shorter time. It comes out of the heap in such a condition as farmers desire to have it, that is, it is dry and crumbly, and fit to spread equally upon the land. And if the owner finds the compost too dry in the heap, he may make holes with a pole, from the top to near the bottom of it; which holes being repeatedly filled with the running of a dunghill, or other liquid manure, it will spread and penetrate through the whole body of the compost, renew the fermentation, and improve the quality of the manure.

With respect to the quality of the earth to be used for composts, where several sorts can be had at nearly the same expence, there is little doubt to be made that some are preferable to others. All writers on agriculture, ancient and modern, agree in recommending the superinductions to be of a different quality from the land to be improved; to lay sand and light earths upon clays and strong land, and the contrary; and, as experience has shewn this to be the most beneficial way of improving land, there is little room to doubt of the propriety of observing the same method, in making choice of some earths, preferably to others, to mix in composts suitably to the kinds of land to be manured. The dung and other putrescent parts in such compositions, are dissolved and lost in a short time: but the earths, consisting of hard solid parts, remain, and become a part of the soil.

Farmers, especially if they live in countries that do not abound in cattle, may be apt to ask, where they are to get sufficient quantities of dung necessary for carrying the practice of agriculture still nearer to perfection? M. de Fourbilly answers this question, by pointing out the following method of making an artificial manure.

"Before the winter sets in, says he, that is about the middle of November at farthest, husbandmen should cleanse all the yards, and out-lets belonging to the farm-house; lay them smooth, and, if necessary, dig away a little of their surface till it is about a foot lower than the floor of their buildings; then if they have any common or waste land, let them bring from thence fern, thistles, and other coarse weeds, cut down in full sap, at which time they are best, or occasionally as they are wanted, and lay a bed of them,

about two inches thick, upon the places thus prepared. If weeds cannot be got, coarse wheat or rye straw may be used in their stead, in beds about half as thick. A layer of earth, about six inches deep, should be spread upon this bed of weeds, or straw. Earth of a quality proper for the improvement of the soil intended to be manured is undoubtedly the best; though any earth, which in this case the farmer will dig as near to the house as he conveniently can, is preferable to the mistaken practice of paring off the upper soil, or turf, of the nearest common or waste land, to mix with the artificial manure: for when poor ground has lost its surface or sward, it long remains a barren spot, before a new soil, capable of affording root and nourishment for grass, can be formed upon it. If no proper earth lies nearer at hand, the farmer may take off the surface of any part of his ploughed ground which lies too high, and is not at too great a distance. But, as much as possible, he should adapt the earth mixed with this manure to the nature of the land for which it is intended.

"This bed of litter and earth should be let lie about a fortnight, during which time all sweepings and filth of the kitchen and house should be thrown upon it, that nothing may be lost, which can be converted into manure. The wetness of the season, and the passing of men, cattle, and carriages, over this bed, will greatly contribute to rot it; to complete which, let the farmer turn in all his cattle of every kind, and drive them backward and forward over it, after rain has fallen. This will soon render it a kind of coarse mud mixed with litter, which may be cleared away at the end of another fortnight. If it be too liquid, as it often is in rainy seasons, it should be laid up in little heaps, upon the same place, till it be drained. Let it then be carried to a sufficiently capacious hole, or pit, dug for the purpose in or near a corner of the farm-yard. This pit must be in a dry place; for no manure should ever be laid in water, which would wash away its unctuous parts, destroy its heat, dissolve its salts, and even lessen its bulk considerably, if it run off elsewhere. One load of stable and other dung should be mixed with every two loads of this artificial compost, as it is laid in the pit. The next day another bed of litter and earth may be spread in the yard, &c. as before; and, being managed in the same manner, will be fit for carrying to the dung-pit in about another fortnight. Thus two supplies of this artificial dung may be had every month, during the whole winter, and part of the spring.

"This work will not be expensive: every body, even women and children, may be employed at it, and it is done at a time of the year when labourers are least wanted in the field. It may be continued in the summer: though the beds do not rot near so soon in dry weather; two or three months being sometimes requisite then to bring them to a proper state, in the above method. However, this may be considerably hastened, and much improved, by bringing cattle to lie upon them in the night, unless they are in folds. The earth and other substances of this manure will be greatly enriched by their dung and urine, before it is carried to the stercorary.

"As this last made dung will not be sufficiently rotted by the next sowing season, the best way is to lay it in a separate pit, to mellow, for the ensuing year: and it will be still better, if kept two years. The other dung, made in a wetter season, and more thoroughly putrefied at first, should remain about six months in the pit to ripen; and be wetted now and then in dry weather. During this time, it heats, ferments, and acquires an excellent quality. It may be made to suit any soil, and agrees with many lands better than pure dung taken from the stall or stable, than which it is milder, less fiery, and more lasting. Farmers who have not a large yard belonging to their house, may make this compost in any other place that best suits their convenience; and the poorer sort of peasants may do the same. By mixing with it a third part of other dung, they triple their quantity of manure." *Memoirs sur les Desfrichemens*, p. 78.

This easy and profitable method of making artificial dung is likewise recommended by the ingenious author of the *Dissertation on Agriculture*, published in the *Memoirs of*

the truly laudable society established at Berne, for the Improvement of Rural Economy.

"There are, says he, two ways of meliorating land. One of them may be called natural, and the other artificial. The former consists in a well proportioned mixture of two or three different kinds of earth, the result of which is a new sort, more favourable to vegetation; and the latter in dung.

"Dung consists of animal or vegetable substances, either actually putrefied, or in a state of putrefaction. It operates two ways upon the earth: first, by conveying nourishment to the plants which grow in it, as the air and water also do; and secondly, by opening its pores and separating its parts, by a kind of fermentation, till at last it is itself converted into a kind of fine black mould.

"The only way to have plenty of this useful matter, without much expence, is by a mixture of straw or litter with the excrements of animals. Manure may be obtained from every part of animals or vegetables; but a quantity sufficient for a large extent of ground would cost too much. I therefore shall not here speak of sawdust, tanner's bark, ashes, foot, linen or woollen rags, shavings of horn, &c. of which quantities can be had only in the neighbourhood of populous towns; but shall content myself with pointing out the means of increasing dung in countries distant from great cities.

"Agriculture affords an ample field, and very abundant matter, for the most useful of all experiments. Nothing would contribute more effectually to its improvement, nay, to the reducing of it to fixed and certain rules, than for proper persons to try upon different pieces of ground, of similar size and soil, some of the principal methods pointed out by the most intelligent in this art, and compare the issue of their trials, and the several incidents attending them, during a course of years. This is particularly wanted in order to determine the effects, and the quantity most proper to be used, of different manures. To this end, two or three fields for experiment might be set apart, to be cultivated exactly according to a well-chosen and well-digested plan. An exact account should also be kept of every occurrence, disbursement, and produce. Regularity is the soul of all business. Such journals, properly methodized, would give us a clear insight into rural economy, and set order, assiduity, and frugality in so advantageous a light, that every one would be forced to acknowledge them to be the source of riches, and as such would be induced to practise them." *Tome II. Part III. p. 651.*

Another way, and often less expensive, of providing manure is, instead of fallowing and resting the land, at certain intervals of time, to sow it thick with the seeds of the most succulent plants, such as pease, tares, buck-wheat, &c. these ploughed into the land, when in full sap, make an excellent dressing to it, equal to dung, and make it fit to yield good crops of wheat. Red clover is also excellent for this purpose, sown with barley or oats in the spring. It will yield a good mowing crop, and afterwards a crop fit to be ploughed in, as a dressing for a crop of wheat to succeed.

For more particulars respecting dung, see *WHEAT*.

DURZ'D, or *dorzd out*, an epithet applied in the northern counties to corn beaten out of the ears by the wind turning it in the field, or other accidents.

DWARF-OAK, the name of a shrub common in many parts of North America, where it is planted for making hedges and fences. It grows very fast, and becomes so thick by cutting with sheers, that hardly a bird or mouse can creep through it when in full perfection. The acorns are sown in rows or drills, where the hedge is proposed to be made, which admits of being made of a considerable height. Such a fence as this would be a screen from the winds in winter, as well as a security to the inclosure, and therefore a hedge of this kind would be very useful here: and the plant would, perhaps, on further examination, be found capable of being serviceable in some other ways. *Museum Rusticum*, vol. VI. p. 293.

DYER'S-Weed. See the article *WEED*.

E.

EADDISH, or *Eddish*, roughings, or grafs growing among the stubble, after the corn is cut.

EARING, or *Aring*, ploughing, tilling, cultivating.

EARNING, cheese-rennet.

EARS of an horse, should be small, narrow, straight, and the whole substance of them thin and delicate : they ought to be placed on the very top of the head, and their points, when stiled, or pricked up, should be nearer than their roots.

When a horse carries his ears pointed forwards, he is said to have a bold, hardy, or brisk ear ; also when a horse is travelling, he should keep them firm, and not (like a hog) mark every step by the motion of his ear.

To cure a pain in a horse's ears, first cleanse them well, for fear the horse should run mad, and then put in some honey, salt-petre, and very clean water : mix the whole together, and dipping a linen cloth therein to attract the moisture, continue the application till the cure is effected.

To take out any thing incommodious in a horse's ear, put in an equal quantity of old oil and nitre, and thrust in a little wool : if some little animal has got in, you must thrust in a tent fastened to the end of a stick, and steeped in glutinous rosin ; turn it in the ear, that it may stick to it.

If it be any thing else you must open the ear with an instrument, and draw it out ; or you may squirt in some water ; and if it be a wound, you must drop in proper medicines to cure it.

EARTH, the ground, consisting of different modifications of terrene matter.

The earth, which generally presents itself first to the eye, is no particular kind of soil, but, usually, a mixture of the soil underneath, with every adventitious substance, either purposely brought to, or accidentally lodged upon it. From these causes, this superficial earth, commonly called mould, grows and increases yearly in depth ; oftentimes to such a degree, as to form even considerable eminences, especially where there has been a fall of woods and trees, such as birch and beech, which, not being of a constitution to remain long in the ground without rotting, as fir, oak, elm, and some other timber will do, are pretty soon reduced into mould as soft and tender as that in which they were sown or planted.

This surface-earth, and also the natural under-turf earth, to the depth of about a foot, is generally the best and sweetest, being enriched with all that the air, dews, showers, and celestial influences can contribute thereto : for that earth is best, and it is the same with water, which is most exposed to the influences of the sun and air. The fatness of the under-turf earth, drawn up to the surface by the kindly warmth of the sun, spends but little of its vigour in the grafs and tender verdure which it produces, provided no rank weeds be permitted to grow and perfect their seeds ; but maintain its natural force, and is therefore, of all uncultivated moulds, the most grateful to the husbandman.

As the rest of the subjacent earths approach this in virtue, so are they to be valued. Of these there are several kinds, distinguishable by their several constitutions. The best of them is black, fat, and at the same time porous, light, and sufficiently tenacious, without any mixture of sand. It rises in pretty large pieces, and falls into dust, of its own accord, after a short exposure to the air ; but without crumbling altogether into dust, which is the defect of a less perfect sort.

This excellent black mould is fit for almost any thing, without much manure. The farmer is not always so happy as to meet with it : or if there be a small depth of it, other less fertile soils lie underneath, such as clay, gravel, sand, &c. which require different treatment, according to their various qualities. These soils often appear on the surface ; and may be said to be almost barren, till brought by art to answer the purposes of the husbandman. In clays and stiff soils, the component particles have too

close an adhesion to admit the roots of plants with the ease requisite for them properly to seek their food : and, on the other hand, sand, and soils of a light nature, are too loose to give the proper stability to plants, or to retain the mixture necessary to convey their nourishment into them. It will therefore be right, first, to shew how these extremes may most properly be corrected, and then point out the means of keeping the superficial mould in constant heart, to use the language of farmers.

EARTH-BOARD, that part of a plough which turns over the earth. See the article **PLOUGH**.

EATING off wheat in Autumn. See **WHEAT**.

EAVES, the edges of the roof that over-hang the walls of a building.

EAVES-GUTTERS. The troughlets made use of to catch rain-water dripping off the eaves of roofs, are usually formed by nailing two narrow slips of board together : but eaves-troughs made in that manner are liable to warp, and become leaky at the joint ; the bottom ; the most essential part.

Indeed they are pretty universally hollowed out of one triangular piece of wood, with a round-mouthed adze. A piece six to eight inches square, slit diagonally, affords two triangular pieces fit for this purpose. The hollowing is not a work of so much labour as theory may suggest. They are usually made of deal. Gutters thus made are stiffer, and more easily supported, are less liable to warp, and much less subject to leak than those made in the usual manner.

EDDER, the small shoots of ash, hazle, oak, &c. used for binding the tops of hedges.

EDDISH, the same with eaddish. See **E**ADDISH.

EEDGE, the extremity of a border.

EEDGE-GROWN, come up uneven, not ripening all together.

EDIFICE, a fabric, a building.

EFT, a newt, or evet.

ELBOW, a name given by horsemen to the hind-part of the fore-leg, pointing towards the brisket.

ELDER, fuel for fire.

ELDER, the udder.

ELDER, is also the name of a well-known tree, and is often used in making fences, which may be done by taking elder-sticks, or trunchcons, ten or twelve feet long, and sticking them in the bank sloping both ways, so as to form a kind of chequer-work. By this means a fence may be sooner raised than by any other, as the elder is a very quick grower. The wood when large is very useful for turners and mathematical instrument-makers, being nearly equal to the best box, and for many uses surpassing it. *Mortimer's Husbandry vol. I. p. 7.*

ELM, the name of a tree too well-known to need any description, being common in almost every part of England.

Elms are very proper to be planted in hedge-rows, upon the borders of fields, where they will thrive much better than when planted in a wood, or close plantation, nor will their shade be very injurious to whatever grows under them ; but when these trees are transplanted out upon banks after this manner, the banks should be well wrought and cleared from all other roots ; otherwise the plants, being taken from a better soil, will not make much progress in these places. About Michaelmas will be a good time for this work, for the reasons before assigned ; but when they are planted, there should be some stakes fixed in by them to which they should be fastened, to prevent their being displaced by the winds ; and part of their heads should be taken off, before they are planted, which will also be of use in preventing their being easily overthrown by winds ; but by no means should their leading shoots be stopped, nor their branches too closely cut off ; for if there are not some shoots left on to draw and attract the sap, they will be in danger of miscarrying.

These trees are also proper to plant at a distance from a garden or building, to break the violence of winds, for which

which purpose there is not any tree more useful ; for they may be trained up in form of an hedge, keeping them cut every year, which will cause them to grow very close and handsome, to the height of forty or fifty feet, and be a great protection against the fury of winds : but they should not be planted too near a garden, where fruit-trees, or other plants, are placed ; because the roots of the elm run superficially near the top of the ground to a great distance, and will intermix with the roots of other trees, and deprive them of nourishment. Nor should they be planted near gravel or grass walks, which are designed to be well kept, because the roots will run into them, and send forth suckers in great plenty ; which will deface the walks, and render them unsightly.

But, for large gardens, where shade is required, there is scarce any tree so proper for that purpose, being easy to remove, when grown to a considerable size ; so that a person who is willing to have his plantations for shade, in a short time, may procure trees of one foot circumference in their trunk, which will be in no danger of succeeding, provided they are removed with care. And these will take root, and grow again, almost as well as young plants, which is what few other sorts of trees will do ; but then they should be such trees as have been thus regularly trained up in a nursery, and have good roots, and not such as are taken out of hedge-rows, as is by some practised, which seldom rise with any tolerable roots, and consequently often miscarry ; and this has been the occasion of so many plantations of these trees failing : for although some of them may live a few years, yet few of them are of long duration, and they rarely increase much in their stems, but frequently grow hollow, their heart decaying first ; so that they are supported only by their bark or shell, for a few years, and the first severe winter, or very dry summer, they are generally destroyed.

In planting of these trees, great care should be taken not to bury their roots too deep, which is very injurious to them, especially if they are planted on a moist loam or clay ; in which case, if the clay is near the surface, it will be the best way to raise the ground in an hill, where each tree is to be planted, which will advance their roots above the surface of the ground, so that they will not be in danger of rotting in winter with moisture.

When these trees are propagated by suckers taken from the foot of old trees, they are commonly laid into the ground very close in beds, where, in dry weather, they may be frequently watered, to encourage their putting out roots. In these beds they are left two years ; by which time, those that live will be well rooted, though a great many of them generally die ; then they should be transplanted into the nursery.

There are some who raise the witch elm from seeds, which it generally produces in great plenty, and are ripe in April. These should be sown upon a bed of fresh loamy earth, and gently covered ; in dry weather they should be watered, and if the bed is shaded from the violent heat of the sun, it will be of great service to the seeds, for I always observe the plants to come up better in the shade, than when exposed to the sun. When the plants come up, they should be carefully cleared from weeds ; and after they have stood two years in the seed-bed, they will be fit to plant out into the nursery.

Sometimes the common English elm will produce seed ; but it is not so constantly fruitful as the witch elm which seldom fails to produce great quantities, when they have arrived at due maturity : which seeds will fall to the ground, and when they light upon a spot which is not disturbed, the plants will come up in great plenty.

The timber of the common English elm is generally preferred to the rest ; though that of the witch elm is often as good, and is the largest tree, when planted on a kindly soil ; but the Dutch elm affords the worst timber, and never will grow to the stature of either of the other sorts ; so that this should not be cultivated for the timber ; therefore the best way to be sure of the kinds which a person would chuse to propagate, is to have a nursery of stools, in order to furnish layers ; for when they are grubbed up from hedge-rows, there will often be many sorts intermixed, especially if the people who go about to gather them, furnish them ; because they take them indifferently wherever they can procure them ; so that when they are planted out thus blended together, there will be a considerable difference in their growths, which will deface the plantation. *Miller's Gard. Dict.*

ENEMIES of Fruit-Trees. See ORCHARDS.

ERSH, the stubble after corn is cut.

ERGOT, a sort of stub, like a piece of soft horn, placed behind and below the pastern joint.

ESCALLION. See the article SCALLION.

ESPARCET, the same with saintfoin. See the article SAINTFOIN.

ESSE, a provincial word used in Cheshire, to signify ashes.

ETCH, the same with erth. See ERSH.

EVERLASTING PEA, or broad-leaved chickling-vetch, a perennial plant, which grows naturally in some parts of England, is easily cultivated, and the root yields every year a great burden of excellent provender.

These are great inducements for encouraging the cultivation of this plant, which seems adapted to any soil.

" I sowed three years ago, says a writer in the Museum Rusticum, a rood of land, light, and but poor in quality, with this seed : this work was done early in the spring, the land being prepared as for barley.

" I sowed it not in the broad-cast way, as I should have found much more difficulty to keep down the weeds ; but I caused a slight furrow to be drawn the length of the land with a light plough ; and when the seed was thinly sown, or rather dropped into this, another was drawn at a foot distance, in which the seed was dropped in like manner.

" An interval, or fallow space, was then left at least two feet wide ; then two more rows of the vetches, till the whole land was sown. I must observe, that I covered the seed by means of a light harrow with wooden tines, drawn backward and forward across the land.

" When the plants came up, I had them well hoed, to clear the ground of weeds ; and when they grew a little strong, they were set out with the hoe to about a foot distance in the rows, that they might have room to spread and branch.

" The first year they yielded no great quantity of fodder, but they have since made me ample amends.

" The second spring they came up very strong and vigorous, branching out much ; and when I turned a couple of hories in to feed, they were very fond of it, eating it very greedily, though they were taken out of a good natural upland pasture.

" This last summer the land was almost entirely covered, and it yielded a great deal of seed indeed. For experiment sake, I caused a few rods to be mowed just before it flowered, and it made good hay, sweet, without being sticky.

" Before I conclude, give me leave to observe, that when I had cut a few rods of the everlasting pea, to make into hay, a small quantity of it was, by accident, spread thin upon the ground, so as to receive the full action of the sun's rays : this was in a manner spoiled, becoming quite dry, insipid, and brittle, and almost all the leaves dropping off ; but the remaining part, which was dried either in small cocks or thick swarths, made excellent hay. I am, however, persuaded that the last method is by much the best." *Museum Rusticum, vol. I. p. 468.*

EWE, the female sheep. See the article SHEEP.

Mr. Ellis, in his Treatise on Sheep, has given us the following secret, which he positively asserts will make ewes take ram at any time of the year. " Separate, says he, six or more of your ewes from the flock, and give to each half a pint of strong ale, or the same quantity of good October, mellow, silky beer, and not that which is sharp by staleness ; and for giving it in the easiest and safest manner, you may run the ale or beer through a funnel into the ewe's mouth ; and when the ewes have been all thus served, put them into a proper place, not too large, nor too narrow, that the ewes may be confined with one or more rams, that have been a little better kept than ordinary for this purpose. Out of six ewes, that I have known to take ram in this manner, not one of them has failed proving with lamb. By the above method, and the assistance of a sufficient number of hands, an hundred ewes may be thus dosed with strong drink, and if rams enough are provided, they will all presently take ram." *Ellis on Sheep, p. 297.*

EXERCISE, a proper agitation given to an animal body, in order to produce salutary effects.

Exercise duly given to horses that are well fed, is not only the best means of all others to prevent ill habits, but to preserve them in a perfect state of health : for exercise converts the food into good and wholesome nourishment, it

it promotes the circulation of the blood, and all the glandular discharges, so as greatly to enliven the body, and to make way for fresh supplies of aliment. It invigorates the spirits, gives strength and firmness to the muscles and sinews, and enables a horse to endure labour. And when exercise is given abroad, in an open free air, it adds greatly to a horse's vigour, and prevents any disposition to putrid coheions in the blood, which a close stagnated air often produces, and this especially when horses are young, and their appetites strong; for indeed when horses grow old, their appetites are more moderate, and rest is oftentimes more agreeable to them than labour. Nevertheless, exercise is, more or less, absolutely necessary for all horses, young or old: for we may observe, even old horses, when they lie much still, though they are not apt, as young horses, to turn directly sick, and fall into fevers: yet as their blood grows poor, and languid with age, they become subject to many infirmities; as swellings of their sheath and bellies, with other dropical symptoms, and sometimes to obstinate eruptions on their skins, which exercise in a proper degree often prevents.

Horses, by their natural activity, are every way suited to exercise and labour, and in that respect are more useful than any other of the brute creatures; only it depends on us, how they are to be treated, both for their own preservation, and our benefit; and their food ought always to be proportioned according to their exercise. But the time and manner of a horse's exercise is also to be regarded; for if he happens either to be worked at an unseasonable time, or beyond his strength, it will be more injurious to him than if he had not been worked at all. Therefore this general caution is always needful, viz. never to ride a horse hard, or put him upon any violent exercise when he hath been newly fed, and has his belly full of meat or water; but should be moved out at first gently, and he will naturally mend his pace, as his food and water begins to assuage; when his rider may urge him on to further speed, as his business may require.

I need not tell any one, that when a horse is hot with riding, or any other sharp laborious exercise, he should be cooled by degrees, this being known to almost every stable-boy, from custom and use, though it is often neglected through ignorance or idleness, or done with little judgment. And, therefore, when a man has travelled hard upon a journey, or when horses have been driven hard in a coach or chaise, it is not sufficient, after they come to their baiting place, or to the end of their day's journey, to walk them about in hand for half an hour or more, which is usually done, but their pace should also be slackened for a mile or two before they come in, and after that, should also be walked some time in hand, that they may cool gradually before they are brought into the stable, with a thin cloth laid over each, if they have been used to it. This is the safest way with young horses, that have been kept well, and have worked but little. And when such horses come late to the end of their day's journey, or when the weather is so bad, that they cannot be walked about in hand, they should then be well rubbed all over their bodies and limbs, till they are quite cool, without taking off their harness and saddles, and then clothed; for when all the smallest blood-vessels are replete and full, as they must unavoidably be in all strong, and especially in long continued exercise, and the blood extremely heated, and running like a torrent, any sudden chill or damp will produce stoppages and obstructions, where the vessels are the most minute and small, or wherever there is the greatest weakness and relaxation, sometimes inwardly in the lungs, sometimes in the liver and kidneys, and sometimes in the stomach and guts, and other membranous parts; and this is usually followed with inward pain, and inflammation, or with great dullness and heaviness, which, in the end, often produce many untoward disorders; or if the limbs happen to be weak and relaxed, the blood and juices will soon drop down and stagnate there, so as to produce swellings, and sometimes ulcerations, that are troublesome enough to remove, especially in those that have been little accustomed to such kind of labour; for habit and use, in continued exercise, alters the case very much, because that strengthens and invigorates the nerves and sinews, as we observe in some hackney or job-horses, which are so seasoned to their work, that scarce any thing can hurt them. Indeed some of the job horses, that we see endure so much labour, are naturally strong and very hardy, and have at first been carefully managed by their owners, who are not able to

bear the loss of cattle, as gentlemen or men of fortune; and, therefore, we see them generally both begin and end their work with great coolness; and when they chance to meet with horses that they find unable to go through their hard work, they usually make their business only a mere play, that they may not loose their flesh, until they can dispose of them to the best advantage. Another necessary caution for the preservation of our horses, is never to feed them too soon, after they have been heated with exercise. *Gibson's Farriery, vol. I. p. 182.*

EXPERIMENT, a trial of any kind; an essay made in order to discover an uncertain, or unknown effect.

For the several experiments made on wheat, barley, &c. see the proper articles WHEAT, BARLEY, &c.

EYE, the organ of sight in an animal body; or that which represents objects to the mind.

The goodness or badness of the eyes of horses is a thing wherein the best judges are sometimes mistaken; for most people regard the clearness and transparency of the eye, which indeed ought to be considered: but it is worth observing, that horses, before they are six years old, have not that transparency in their eyes which they arrive at afterwards, because, while they are young and growing, their juices are viscid and balsamic; so that their eyes look thicker or clearer, in proportion as their blood and juices happen to be more or less in a good state. The same may be observed in all horses that have colds, when the vessels of the eyes are full: the eyes at that time look thick, and sometimes inflamed; and a blow on the eye, or a bite will have the same effect, when there is not the least danger of blindness.

It is not, therefore, always the clearness of the eye that denotes its goodness; but a man is also to form his judgment from other indications, particularly from the form and manner of the eye, which includes not only the body of the eye, but the eye-lids, eye-brows, and all the parts belonging to it. Many good-eyed horses have a heaviness in their countenance, with a lowering brow; yet great numbers of this aspect go blind with cataracts when they are about seven years old, or between seven or eight, and sometimes later. These are the most suspicious where there is a bunch or fullness between the upper eye-lid and the eye-brow, with a fullness round the under eye-lid; so that the eye appears as if it was environed in a ring. Such horses are often fleshy about the head and jaws, which, upon every cold, or rather slight accident, exposes them to defluxions in their eyes.

When the eye is extremely flat, or sunk within its orbit, it is always a bad sign, even though there be no defluxion or humour upon it: a small pig-eye is none of the best, nor a large goggling eye. The one often perishes for want of nourishment, occasioned by some defect in the nerves or the arteries that supply it with blood; the other by being too much exposed to accidents, and by having too great supplies of nourishment.

That eye is almost always weak which is of a longish oval figure, especially when the two corners are narrow, like the shape of an almond. When the coat or membrane, that rises from the under part of the eye happens to be large and thick, so as to press the eye-ball, and the caruncle or kernel on the inward corner next the nose is spongy and moist, though there is sometimes a remedy for this defect, yet such horses in the end generally go blind.

When the eyes are bad, the muscles or movers of the eyes are generally weak: so if the eye looks dead and lifeless, the best way of trial is to hold up the horse's head, in the same manner as when a drench is to be given, which will draw the eye upward; and if it remains there, fixed and immoveable, or has a languid motion, it is a pretty sure sign the eye is bad. And this trial will, for the most part, hold good, whether the eye be moist or dry.

Some regard the colour of the eye, which, however, is different, according to the difference of colour in horses; and indeed we are so far to regard the colour, that if the iris or circle that surrounds the pupil or sight of the eye be distinct, and of a pale variegated cinnamon colour, it always denotes a good eye. For the iris is always most distinct, where the humours of the eyes are most clear and pellucid; and those horses have the best eyes, which in colour resemble the eyes of a sheep or a goat; but few horses arrive to that perfection of colour and transparency, till they are at least six years old or upwards. On the other hand, if the iris or circle round the pupil be of a dark muddy colour, and does not appear distinct and variegated,

tinged, till one approaches near the eye; and if the narrow sky-coloured verge, which we observe more or less in most horses on the outside of the iris, happens to be of a milky hue, it is no good sign. Nevertheless, wall-eyed horses have, for the most part good eyes.

Some, in examining the eyes, have a regard to the colour of the horse, which I take to be no sure way of judging; for as there are good horses of all colours, so there are good-eyed horses of all colours. The grey, especially the pigeon or dove-coloured grey, are the most suspected; also the iron-grey, and the dun, &c. But I think I may say, from experience, that whatever colour is the most common among the horses, so as to exceed in number, abounds most with bad eyes: and I have observed as many bad-eyed horses among the black coach breed as any other.

Most people, in examining a horse's eyes, lead him under a gateway, or some shade, that they may see perfectly the colour and transparency of the eye: but the best way is to observe his countenance when he comes first out of a dark stable into a strong light; for if he has any weakness in his eyes, he will wrinkle his brow, and look upwards to receive more light; and if the pupil at the same time be large, it is a bad sign; and therefore the best way is to look to a horse's eyes first in the shade, to observe the dimensions of the pupil; and if that lessens upon his coming out into a strong light, it is almost an infallible sign that the eye is good.

Some suspect all horses that startle to have bad eyes: indeed many bad eyed horses are apt to startle: but a horse that starts and looks upwards, lifting his feet high when he moves, as if afraid to touch the ground; such is more likely to have bad eyes than one that startles; for many horses startle merely out of fear, and I imagine not a few from some defect in vision, viz. from seeing objects indistinctly at some distance; in all which cases the eyes may be strong and durable, though many fancy them to be weak. But if a horse frequently startles when no object is before him that might cause him to startle, we may then suspect his eyes to be but indifferent.

Upon the whole, that eye is generally good where the

eye-lids are thin, where the outward coat or tunicle of the eye is also thin and delicate, where the caruncle next the nose is small and dry, where the eye is transparent and sprightly, when a horse has a bold resolute look, and takes notice of objects without fear. On the other hand, when a horse moves his ears backwards and forwards, and seems surprised at every noise or motion of the hand, when he raises his feet high, is uncertain in his walk or step, and unequal in his goings, when his eyes appear full and swollen, with a fleshy circle round them, or when they are sunk or flat, or of a longish oval figure, when the outer coat is thick, and covers a great part of the eye-ball, and the glands or kernels of the eye are spongy and moist; all these denote the badness of the eyes, and are often the forerunners of blindness. *Gibson's Farriery, Vol. I. p. 14.*

EYE of a tree, a small pointed knot to which the leaves adhere, and from which the shoots or sprigs spring forth.

EYE, among gardeners, implies the small bud or shoot inserted into a tree.

EYE-LID, the membrane that covers the eye.

If the eye lid of a horse is wounded and cut through, and the cut divides it so as the lips part one from the other, it ought to have a stitch with a straight needle, such as the surgeons use for superficial wounds, and not to be drawn too close, but just so far as to bring the edges together; and this is yet the more necessary, when the eye-ball happens to be wounded through the eye-lid, that there may be room for the discharge of the matter. I have observed that the eye-lid requires but one stitch; for when there are more, and these pursed together, as the farriers generally do, and the lips drawn close, such stitches will break in twenty-four hours, and leave the wound in a worse condition than it was at first.

The proper dressing for wounds of the eye, is honey of roses, and tincture of myrrh, viz. one dram of the tincture to an ounce of the other. The best way of using it is to dip a pledgit of lint in this mixture, made warm, and applied to the wound, for tow and hurds are too harsh for the eye. This dressing may be repeated once a day, until the wound is healed up and cicatrised, and it will seldom fail of success. *Gibson's Farriery, Vol. I. p. 320.*

F.

FALLOW, land ploughed, but not sown, being left to rest after the years of tillage.

If the farmer finds that one summer's fallow does not entirely answer the purpose of dividing and loosening the earth, it is his interest to continue it with another. M. Tull confirms this, by instancing a poor man, whom necessity compelled to take this method, because he could not get seed for his ground after he had tilled it the first year. The consequence was, that his crop was worth more than the value of the land it grew on. Mr. Maxwell too mentions another, who, from a like necessity, followed the same course upon almost his whole farm, had such a crop as enabled him to pay many debts, and, by continuing the same practice, came in a few years to be in a condition to purchase the farm.

When the husbandman intends to break up any piece of land, the first thing necessary, is carefully and judiciously to examine the surface of the ground, and its depth. If the surface be covered with a thick, strong, fibrous turf, and the mould underneath sufficiently deep, his best, and indeed the only right method of proceeding, is excellently well directed by the marquis of Turbilly. But, if on the contrary, the upper mould should be shallow, or so thin turfed as not to be fit for burning, he must observe whe-

ther his soil be of a strong, or of a light quality. Under the former of these are included all deep, hard clays, of what colour soever: all stiff binding earths, and such as, after being exposed to the sun, or frost, grow hard and stony; with such as chop and cleave upon their surface in the heat of summer: and under the latter are ranked (the repetition may be excusable here for the sake of perspicuity) all sandy, mouldering, gravelly, mellow soils; all loose and open earth, of what nature soever; all such as are not sticky, but will soon dry after rain; and, instead of lying in great lumps after ploughing, are easily apt to dissolve, and crumble into mould, not being subject to bind by the heats in summer, or frost in winter.

If, upon examination, the soil is found to be of the stiff kind, particular care must be taken to turn down its surface in the latter end of autumn, that what fibrous roots there are in it may be more effectually rotted against the summer ploughing; and that the earth may be mouldered, or mellowed, by the winter's frost and rains.

When ploughed land is intended to be fallowed, it should likewise be ploughed in the autumn, as soon as the seed time permits, and laid as rough as may be, especially if it be a stiff soil, that the winter's frost may mellow it.

In the spring, the farmer should take the earliest opportunity

portunity that his spring crops may admit of, to give his fallows a second ploughing across the former; after which, the ground should be well harrowed, not only to break the clods, but to pull up such roots as are not yet rotted, that they may be gathered into heaps and burnt. It is essentially necessary that this, and all the following ploughings and harrowings be performed in dry weather; because, as the purpose here is thoroughly to loosen the mould, special care should be taken to avoid everything which might counter-act that intention. The farmer cannot wish for a greater benefit to his husbandry, than moderate showers after each fallow, to bring the seeds of every weed to vegetate; in order that, being turned down by several ploughings, they may be the more effectually destroyed.

It seems needless to mention when the future ploughings should be given, because the farmer should take every opportunity of repeating both them and the harrowings, in full confidence that he cannot over-do it, especially in strong soils; in which he may also be equally certain, that he cannot err in ploughing too deep: for it is of great consequence, not only that the roots have a sufficient depth of mould to penetrate in, but also that the cold clay be removed to as great a distance as possible from the surface; because by its retaining the water, the roots of plants are chilled and killed, especially in the winter, when they reach such stagnating wet. If any manure is applied to alter the quality of the soil, it cannot be laid on too early in the summer, that the ploughings may the more effectually mix it with the earth; but if only compost be used for enriching the soil, it need not be spread till just before the last ploughing.

Mr. Marshall says, if a summer-fallow be thoroughly clean from root-weeds, it is certainly most eligible management to sow it with the seeds of some quick-growing herbage, in the wane of July, or beginning of August, to be ploughed-in for wheat in the wane of September: but to lay up a fallow in the beginning of July which is not perfectly cured of its couchiness, is very indifferent management.

Authors give directions for ploughing land into many different forms, mostly arising from the different natures of soils, but too often from the particular long established custom of countries, the reasonableness of which is not always sufficiently considered.

Where there is a descent for water, all lands should be laid flat, because, in that way, the rains will undoubtedly give a more equal nourishment to the crop, than when they are raised in ridges. The practice of laying light soils into narrow ridges, for wheat, is certainly owing to want of attention; and even in strong land ploughed for winter fallowing and sowing, we are much inclined to think that the best way would be, instead of single bouts, or narrow ridges, to make the ridges very broad, and lay them up high: for if the ground is level, the water will lie in the parting thorough, and, by soaking into the sides of the ridges, make it so poachy, as to render it very unfit to be worked, till late in the spring, unless the season be very dry; or, if there is much descent, great part of the best soil will be carried off. For the same reasons the sides of hills should always be ploughed almost, but not quite, horizontally, that the parting thorough, lying open, may serve for drains to the water: besides which, the ploughing of such declivities in this sloping manner is by much the least laborious both to men and cattle. The furrow here should always be drawn oblique, as Columella directs, sometimes a little toward the higher, and sometimes toward the lower part of the hill, so that the direction may be altered in each subsequent ploughing.

The erroneous opinion of those who imagine that the surface of the ground is considerably enlarged by ploughing it into high ridges, and that it therefore affords a larger space for the growth of plants, is thus judiciously refuted by M. Duhamel.

"The produce of a sloping surface is not greater than that of a plane equal in extent to the base of the slope: for as the plants grow perpendicular to the horizontal base, there is no point of the slope which does not answer vertically to a point of that horizontal base: therefore supposing the furrows of a piece of ground ploughed in broad lands to be six inches deep, and the ridges six feet wide; the slope from the bottom of the furrow to the middle of each ridge will be one foot in six, which is indeed considerable: but still the surface of the ridges will be to that of their horizontal base, only as seventy-six are to seventy-five: a

small advantage; especially when compared to a sixth part of the ground, which is taken up by the furrows, and in which no corn is sowed."

Another, and that very essential advantage of fallowing, not yet sufficiently insisted on, is the destruction of weeds, which are one of the farmer's greatest enemies. By weeds, we here mean every plant which grows spontaneously in the field, without having been purposely sown, and which it is not the husbandman's intention to cultivate. All these should be rooted out. It would be needless to enumerate them after this general definition; and perhaps equally so to observe, what every husbandman must know, that cockle, daniel, fox-tail, wild poppies, wild vetches, wild oats, dog's grass, colt's foot, melilot, knot-grass, thistles, and charlock, are the most hurtful species of these noxious growths, and the most difficult thoroughly to extirpate.

To prevent the increase of weeds, they should be destroyed before their seed is ripe: but that is not possible in lands which are ploughed in the common way; because, as they grow intermixed with the corn, and ripen sooner than wheat, their seeds sow themselves; neither can they be extirpated by resting the land; for the seeds of some of them will remain sound several years in the earth. If a field in which there are many poppies, or red weeds, as they are called in some places, be sowed with saintfoin, scarce a poppy will appear the second year: but when the saintfoin is ploughed up, even at the end of nine years, the red-weed frequently appears a-new, which can hardly be owing to any other cause, than that its seeds have remained sound in the earth during all that time; for very few of them, in proportion to the quantities which spring up, can have been brought from the neighbouring grounds, or in dung. This is confirmed by an experiment which M. Duhamel made. He ordered the earth, with which a ditch had been filled fifteen or twenty years before, to be dug out, and spread upon a piece of ploughed land. Several plants, of different kinds from any that were in the field, sprouted up in the place where this earth was laid. Consequently they were produced by seeds which had remained sound in the ground, during the fifteen or twenty years that this earth had lain in the ditch.

This is an important reason for ploughing thoroughly all lands which are fallowed; for it is certain, that as numbers of seeds shoot up during the fallow, repeated ploughing will destroy many of them. But there are several kinds of plants, such in particular, as wild oats, and fox-tail, the seeds of which do not sprout till they have remained two or three years in the earth; nor will culture make them grow sooner. Such, at least, is M. Duhamel's opinion, as well as that of several other very ingenious gentlemen, though it must be confessed, that some late experiments seem to contradict it, and to shew that the seeds of those plants which he says require being three years in the ground before they will grow, were only buried so deep, in the case he mentions, as not to be able to vegetate, which they afterwards did when laid within reach of the influences of the air, rain, dew, &c. If so, though the increase of weeds may be prevented for several years, by ploughing, cutting, pulling them up, &c. yet it is evident, that the repeated ploughing of fallow lands, far from immediately destroying these kinds of weeds, will rather help them to grow, when their seeds are brought within a proper distance from the surface, and their time of sprouting is come. But then, allowing that some of their seeds may be thus brought up by each ploughing, for a while, it cannot be long before all of them will have sprouted, after which the ground may be kept quite clear, with proper care.

Husbandmen have not yet found a more effectual method to destroy weeds, than by sowing the ground out of season; that is to say, by sowing oats the year that barley should be sowed. It has been experienced, that by this means, some kinds of weeds have been destroyed, which, appearing only every third year, never shew themselves, in the usual rotations, but amongst wheat. But the farmer loses a crop by this means, and still has so many weeds left, that he is obliged to hire people to weed his corn. This is done two ways.

A number of women place themselves, in a row, and, with a hoe made for the purpose, cut up all the weeds they see, such as thistles, blue-bottles, poppies, &c. But many of these, when young, frequently escape their notice; in which case the hoeing must be repeated when they are grown

grown larger; and the smaller weeds, such as wild vetches, wild oats, darnel, knot-grass, fox-tail, young poppies, &c. which are at least as hurtful as the other, remain in the field. Besides this, in cutting the weeds, it is scarce possible not to cut down some of the corn; and the roots of the thistles and other biennial plants which are cut, produce two or three new stalks in lieu of the old one; by which means the evil is increased.

The other method of clearing corn, is by hand-weeding it; but this is seldom practised by farmers, because it is too expensive: and indeed the women and children generally employed to do this work, most commonly pull up a great deal of corn with the weeds; so that, what with that, and with their trampling, and dragging their bags of weeds over it, they frequently do more hurt than good, especially if the earth be moist.

The surest way to destroy weeds, is to continue ploughing while the corn grows: but this can be done only in the new husbandry.

Weeds may be ranked under four general classes: first, such as have creeping perennial roots: secondly, such as grow in cold wet soils: thirdly, such as are of a large succulent body: and, fourthly, such as having small seeds, or seeds which ripen before the corn, sow themselves. Each of these require a different treatment.

The first sort cannot be destroyed but by repeated summer fallows, by which their roots are cut, and turned up to be withered by the sun and winds, after which they are dragged out by harrows, and should be burnt. This, repeated as often as a farmer conveniently can, especially during a dry season, can scarcely fail to have the desired effect. Colts-foot, which is propagated by the root, and is a very pernicious weed, may likewise be destroyed by sowing the ground with rye-grass, or any plant which, coming up early in the spring, shade and smother it; for that will kill it in a few years. The second kind are destroyed by draining the earth of its superfluous moisture, and by manuring it with lime, ashes, gravel, shelly sea-sand, and other proper correctives for such soils.

The third are extirpated by cutting them down when in full sap and vigour: for the sap being thereby suddenly interrupted in the course of its circulation, stagnates in the roots, and putrefies there. A few weak lateral shoots may be made; but if they are likewise cut in the same manner, the roots will putrify intirely by degrees, and instead of annoying, will become a manure.

The fourth class can be destroyed only by frequent fallows, and constant cutting, or rather ploughing them down before they run to seed. Some, for instance, the wild oats, may be mowed for hay: but it is much more beneficial to the land to plough them in: because, by that means, instead of being exhausted by frequent crops, it is manured by those enemies to useful grain.

Mr. Marshall, in his *Rural Economy of Yorkshire*, vol. I. p. 361, says,

"There are several species of weeds which cannot be overcome without fallowing. Weeds which propagate their species by suckers from the root, are invigorated by a single plowing, which, by giving a fresh supply of air and openness to the soil, gives freedom to the suckers; while the mere seed-weeds being destroyed in the operation, the suckers are left in full possession of the soil: and whoever attempts to lessen the number of such weeds with the hoe, is unacquainted with the practice of husbandry.

"The continuance of a fallow, and the number of plowings requisite, depend on the season, and on the number and the nature of the weeds to be destroyed. If the spring season be found insufficient to effectuate the purgation, take the summer, and even the autumn, the winter, and the ensuing spring, rather than crop an under-worked fallow, which is but little superior to a single plowing. One stirring towards the close is frequently more valuable than two or three plowings at the outset. To begin a fallow without continuing it until its intention be fully accomplished, is throwing away labour unprofitably."

Fallowing is an important operation in agriculture; the beneficial effects of it consists in three particulars. 1. The repeated cultivation of the lands, the most effectual method of extirpating weeds: if they are annual weeds, the seeds of them are encouraged to grow, and the next ploughing buries and kills them. And if they are large perennial weeds, the earth being loosened by the tillage, the large weeds are then easily pulled out by harrows, and then dried and burned. 2. The land is opened and pulverised to a

great degree of fineness, by the repeated tillage; and, 3dly, by the turning of the mould often; a new surface is every time exposed to the atmosphere, whereby the soil is impregnated through its whole substance, with the fertilizing particles that enrich the earth. No person of observation, conversant in agriculture, can doubt of this effect of the air or atmosphere, enriching of well cultivated land that is exposed to it, and is abundantly proved by the new husbandry.

From this description of the benefit of a good fallow, it will be evident, that the common fallowing is far short of answering the purposes of good fallowing. Three, or sometimes four ploughings of land, where the furrows are turned over almost whole, and couch, and other rank weeds are suffered to grow up for feeding sheep, do not deserve to be called good fallowing, as not one of the ends of good fallowing are attended by such slovenly culture.

Thorough good tillage, in whatever manner performed, is greatly beneficial to land; but one of the most effectual methods of fallowing, is to lay the land up in high, narrow one-bout ridges, which are easily cultivated with a plough, that has a doubled finned share, and a double mould board. The share of such a plough being entered in the middle, and drawn along through one of these narrow ridges, splits it in the middle, turns the mould equal to the right and left, and ploughs one of them at one draught; and the mould of each ridge, is thus raised into a new ridge upon the former furrow. The ridges are sometimes harrowed down, which will well mix the mould, and pull up the large weeds and roots, and then the ridges are raised again as before, across the former ridges, if that can be conveniently done, if not, the new ridges, if they do not stand exactly where the others did, will be composed partly of the earth that may have been misfired by the former ploughings, and the land will by that means be all tilled to an equal depth.

By this way of ploughing, the ridges are tilled, each at one furrow, and if they are three feet broad, would, in common ploughing, require four furrows to plough them on level ground, and time in proportion, to do the work. The mould in this way, is also made so fine and light, that two horses will commonly plough as much ground as three or four can do, when it is out of tilth, and bound together by weeds. The tillage should be performed when the earth is dry, and repeated as often as the weeds spring up: for they should not be suffered to grow large, much less to run to seed.

The farmers cannot by common fallowing extirpate the weeds, and clean the land well in one year, and few of them are willing to fallow another year. But in this method of fallowing, the weeds may be conquered in one winter and summer, and when once the land is made clean, it may be kept so, by a proper change of crops, and the hoeing husbandry.

Mr. Young, in his *Annals of Agriculture*, vol. IV. inserts the following letter, from A. Songar, esq. his imperial majesty's consul in Great Britain. "Some correspondents of yours having requested to know whether summer-fallow, or constant crops, be most advantageous in the management of arable land, I think it may be proper to mention the course of crops which are pursued in the province of Ghjara d'Adda:

"First year. Plough once for wheat after maize; which wheat is harvested before the end of June; the land is then dunged and ploughed for millet, or panick; which second harvest comes in September.

"Second year. Break up for winter fallow; and ploughed again once in the spring, and sown in May, with the largest kind of maize; harvested in September.

"Third year. Plough once for wheat; with which wheat clover is sown in the spring; and dunged in autumn.

"Fourth year. Tender clover mown twice, sometimes three times for hay; and watered when wanted.

"Fifth year. Ploughed once for wheat; and after the wheat is harvested, ploughed for millet, or maize of smaller kind.

ANOTHER COURSE.

"First year. Plough once for wheat; and after the wheat is harvested, plough once more for millet.

"Second year. Plough several times, till the land is very fine and well-manured for flax. The management of it in very high perfection: pulled in June: ploughed and sown with maize; harvested in September.

"Third year. Plough once for wheat, harvested in June, and broke up directly for a fallow, which fallow consists of three

A Fallow-cleaning Machine,
Manchester in Lancashire.

Invented by M^r Aaron Ogden, a Smith at Ashton Underline, near

Fig. 3.

Fine Bent

three ploughings ; on the third of which are sown promiscuously cole-feed and lupines, that are ploughed under in autumn for wheat ; which wheat produces better than any other, except that upon clover.

"It should be observed, that millet, every sort of maize, panick, &c. for seed, are hoed ; and flax weeded. And from hence it appears, that we know nothing of what you in England call a summer fallow ; for, on the contrary, we think our land might be covered with some kind of crop ; a due arrangement of which constitutes the best husbandry practised in that part of the duchy of Milan."

Mr. Young also observes that, "this communication is very valuable : here is land in the constant succession of yielding two crops a year, and yet keeping the soil thus incessantly productive, is so far from exhausting it, that its crops are all profitable : this fact is applicable in all climates, and ought to be considered as a striking lesson in England."

FALLOW, also signifies a pale red colour.

FALLOW-CLEANSING Machine, an instrument invented by Mr. Aaron Ogden, a smith at Ashton-under-Line, near Manchester, in Lancashire.

This machine, which bids fair to be of very great use in husbandry for cleansing fallows from weeds, &c. which waste the riches of the soil, will be very easily understood from the drawing we have given of it on Plate XV. fig. 2. Where

A, A, is the frame ; B, the first roller ; C, the second ditto, in which last are two cranks to move the arms D, D, which work the rake up the directors fixed on the plank E. The under side of the lower ends, or shares, of these directors, are sharp to cut the clods, and let them come on the upper side. Each alternate heel of the share is longer than the intermediate one, that they may not have more than one half to cut at once.

At the back of the plank E, are two screws to let it loose, that the directors may be set higher or lower. The shares are to penetrate the ground two or three inches, to raise the quicks till the rake I, I, fetches them into the cart H, where a man must be ready with a muck-hook to clear them backward when gathered.

In the rake I, are teeth for every space of the directors, that stones, &c. may be gathered without damage.

K, K, are two staples, by which the machine is drawn : under them at b, are two hooks, placed low to raise the machine in turning, by the help of the traces ; and the axle-tree of the cart should be fixed upon a pin, that it may turn like a waggon.

F, F, are the triggers to throw the rake behind the roots. The long teeth at G, G, are to cleanse the roller C.

I, I, is the rake which gathers up the weeds into the cart H, and is drawn above the trigger F, by the working of the arms D, expressed by the dotted lines at d d, i i i.

The triggers F, of which there is one on each side, move on the pivots a ; so that when the points b, of the rake I, having been drawn up by the directors E, to the part marked c, the trigger, giving way, permits the rake to pass ; but immediately falling, the rake returns along the upper surface of the trigger marked e, e, and of course falls on the weeds when it comes to the end, a little beyond the pivot a.

The reader will observe that the boarding is taken away on one side, in the plate, in order to give a more perfect view of the inner parts of the machine ; and, in fact, it would, perhaps, be better, if all the boarding, marked L, L, L, was taken away, and frame work put in its stead.

The cart H, might undoubtedly also be made lighter.

The wheels M, M, appear, in the plate, to be made of solid wood ; but there is no necessity they should be so.

At N, is another view of the roller C, by which the disposition of the spikes may be easily comprehended.

Suppose the circle O, described by the end of the roller N, to be divided by four straight lines into eight equal segments, as represented at P. Let the same be done at the other end of the roller, and parallel lines be drawn from one corresponding point to the other, the length of the roller : mark the points with figures 1, 2, 3, 4, 5, 6, 7, 8 ; afterwards draw oblique lines, as from 1, at the end O, to 2, at the other end, and from 2 to 3, &c. on these oblique lines the spikes are to be fixed, at equal distances, in eight circles, described on the circumference of the roller.

The spikes of the small roller B, are fixed in the same manner, except that the diameter being smaller, there are only six instead of eight rows.

R, is another view of the directors, with the plank E, on which they are fixed ; and S, is a section of a part of

the plank, with one of the directors as fixed, in which may be seen the heel m, from whence to the point of the share n, is a sharp cutting edge. See the same letters in figure R.

At T, is one of the long teeth to be seen at G : it is bent towards the roller C, which it serves to cleanse. When the end of the rake b, after rising above c, is pushed, by the motion of the arms D, D, along the upper part e, e, of the trigger F, and comes to the end beyond a ; as it falls, the part of the arm, marked o, rests in the notch p, till it is again raised by the motion of the roller C, with the rake.

The roller C, is to be one foot diameter, the spikes nine inches long, that they may go through the furrow (if the soil should be loose) into the hard earth, the more effectually to work the rake, which otherwise might be so overcharged as to cause the roller to drag without turning.

In the rake-ends b, there should be pivots, with rollers or pulleys on, to go in the groove, to take off the friction ; and they would likewise take the triggers more surely as the rake comes back.

The rake should also be hung so far backward, that when it is fallen, the arms of it may lie in the same plane, or parallel, with the directors, on which it comes up (which will require the frame to be two inches longer in the model.) This will cause the rake to fall heavier, and drive the teeth into the roots, and bring them up without shattering. These teeth must be made of steel, very fine, and so long as to reach down to the plank on which the directors are fixed, that is to say, six inches long (the directors are also to be made six inches broad above the plank.) The rake-head should also fall a little before the crank is at its extremity, which will cause the rake to push forward to let the teeth come into the roots. The rake-teeth must drop in the same plane with the roller and wheels, or on the surface of the earth. No more space should be given from the roller C, to the long teeth, at G, G, than that the rake may just miss the spikes of the roller C, and fall on the places before mentioned.

As the first roller B, was intended to cleanse the second C, more than any other use, it may be omitted when the machine is made in large, as Mr. Ogden has lately found that the long teeth at G, G, answer the end alone, and this renders the machine about a sixth part shorter.

Now, to suit any sort of earth, there should be to each machine three planks, with directors at different spaces, to use occasionally : in the first, the spaces between the directors should be eight inches wide, in the second six, and the third four. This will answer the same end as having so many machines.

As there may be some objections to the rake not leaving the roots when it has brought them up, Mr. Ogden has several methods of cleansing it ; but as he would make it as simple as possible, he chuses to let it be without them at present : but suppose it should bring some roots back again with it, it will probably lose them before it gets back to the extremity ; whence they will lie light, and be of but little detriment to the others coming up.

Mr. Ogden would have the first machine made four feet six inches wide, the teeth divided into equal spaces, the out-sides into half spaces.

FAN, an instrument for winnowing corn. See the article **THRASHING**.

FAN GOME-CORN, thin or light corn, that which has but little bulk or solidity.

FARCY, or *Farcin*, a distemper to which horses are too often subject. It is a disease of the blood vessels, generally following the course of the veins, and when inveterate, thickens their coat and integuments.

At first one or more small swellings, or round buds like grapes or berries, spring out over the veins, and are often exquisitely painful to the touch ; in the beginning they are hard, but soon turn into soft blisters, which, when broke, discharge an oily or bloody ichor, and turns into very foul and ill-disposed ulcers. In some horses it appears on the head only ; in some on the external jugular ; in others on the plate-vein, and runs downwards on the inside of the fore-arm towards the knees, and very often upwards towards the brisket ; in some the farcy shews itself on the hind parts, about the pasterns, and along the large veins on the inside of the thigh, rising upwards into the groin, and towards the sheath ; and sometimes the farcy makes its appearance on the flanks, and spreads by degrees towards the lower belly, where it often becomes very troublesome.

When the farcy appears on the head only, it is easily cured, especially when it is seated in the cheeks and forehead, the blood-vessels being here small ; but it is more

difficult when it affects the lips, the nostrils, the eyes, and kernels under the jaws, and other soft and loose parts, especially if the neck-vein becomes chorded. When it begins on the outside of the shoulder or hips, the cure is seldom difficult; but when the farcy arises on the plate-vein, and that vein swells much, and turns chorded, and the gland or kernels under the armpits are affected, it is hard to cure; but more so when the crural veins within-side of the thigh are chorded, and beset with buds, which affect the kernels of the groin, and the cavernous body of the yard. When the farcy begins on the pasterns or lower limbs, it often becomes very uncertain, unless a timely stop is put to it; for the swelling in those dependent parts grows so excessively large in some constitutions, and the limbs so much disfigured thereby with foul sores and callous ulcerations, that such a horse is seldom fit for any thing afterwards, but the meanest drudgery: but it is always a promising sign, wherever the farcy happens to be situated, if it spreads no farther. It is usual to affect only one side at a time, but when it passes over to the other, it shews great malignancy; when it arises on the spines, it is then for the most part dangerous, and is always more so to horses that are fat and full of blood, than to those that are in more moderate case. When the farcy is epidemical, as sometimes happens, it rises on several parts of the body at once, forms nasty foul ulcers, and makes a profuse running of greenish bloody matter from both nostrils; and soon ends in a miserable rot.

From this description of the farcy, it will appear how greatly those may be disappointed, who depend on some single specific drink or ball for a certain cure; for the symptoms are sometimes so favourable, that it is easily conquered by a very simple management; and when it arises superficially upon the smaller vessels, it will often go off with moderate labour, without any other means than bleeding. Such instances as these may easily give a reputation to things of no great efficacy, and bring them into esteem: but whoever has acquired any true notion of the farcy, will know that this distemper is not to be conquered but by such things as are fitly adapted to the various symptoms that occur in the different stages of it. To avoid therefore the perplexity that arises from the various complications so usual in the farcy, we shall consider it in its different stages, or degrees, viz. when it seizes only the smaller vessels; when the larger veins are chorded, and the feet, pasterns, and flanks affected; and lastly, when the farcy, beginning on one side only, and breaks out on the other, also, and affects the whole body.

When the farcy makes its first appearance on the head, it rises on the cheeks and temples, and looks like a network, or small creeping twigs full of berries. Sometimes it inflames the eye and sometimes little blisters or buds run along the side of the nose. It arises often on the outside of the shoulder, running along the small veins with heat and inflammation; and sometimes a few small buds appear near the withers, and on the outside of the hip. In all these appearances, the disease being superficial, and affecting only the smaller vessels, is easily conquered by the following method, when taken in time; for the simplest farcy, if neglected, may degenerate into the worst sort.

This distemper then being of an inflammatory nature, and in a particular manner affecting the blood vessels, must necessarily require large bleeding, particularly where the horse happens to be fat and full of blood. This always checks the beginning of a farcy, but is of small service afterwards; and if a horse is low in flesh, the loss of too much blood sometimes proves injurious. After bleeding, let the horse have four ounces of cream of tartar and lenitive electuary; which may be given every other day for a week, to cool the blood, and open the body; and then give nitre, three ounces a day, for three weeks or a month; and anoint the buds and swellings with the following ointment twice a day.

"Take ointment of elder four ounces, oil of turpentine two ounces, sugar of lead half an ounce, white vitriol powdered two drams; mixed together in a gallypot."

The buds sometimes by this method are dispersed, leaving only little bald spots, which the hair soon covers again. When they break and run, if the matter be thick and well digested, they will soon be well: but in order to confirm the cure, and to disperse some little lumps, which often remain for some time on the skin without hair, give the liver of antimony for a month; two ounces a day for a fortnight, and then one a day for the other fortnight; by following

this method, a farcy which affects only the small vessels, may be stopped in a week or ten days, and soon after totally eradicated.

When the farcy affects the larger blood vessels, the cure is more difficult; but let it always be attempted early: therefore, on the plate, thigh, or neck-veins appearing chorded, bleed immediately on the opposite side, and apply the following to the chorded vein.

"Take oil of turpentine in a pint bottle, six ounces; oil of vitriol three ounces; drop the oil of vitriol into the oil of turpentine by a little at a time, otherwise the bottle will burst; when it has done smoking, drop in more oil of vitriol, and so on till all is mixed."

This mixture is one of the best universals in a beginning farcy; but where it is seated in loose fleshy parts, as flanks or belly, equal parts of the oil of vitriol and turpentine are necessary.

Rub the parts first with a woollen cloth; and then apply some of the mixture over the buds, and wherever there is any swelling, twice a day. Give the cooling physic every other day, and then three ounces of nitre every day for some time. This method must be continued till the buds digest, and the chord dissolves; and when the sores run plentifully, the matter digests well, and the lips and edges are no ways thick or callous, you may expect a speedy recovery; yet to confirm the cure, and prevent a relapse, give the liver of antimony or crude antimony, as before directed: and to heal the sores and smooth the skin, dress with bees-wax and oil.

When the farcy begins on the flanks, or towards the lower belly, it often takes its rise from a single puncture of a sharp spur. The pain and smarting is one sure sign to distinguish the farcy from common accidents: the staring of the hair which stand up like a tuft all round the buds or blisters, and the matter that issues from the buds, which is always purulent, and of a clammy greasy consistence, are other certain signs. After bathing with the mixture above mentioned till the ulcers are smooth and healing, should the swelling not subside, to prevent the spreading of the buds, and to disperse them, bathe with either of these mixtures as far as the centre of the belly; and at the same time give a course of antimonials, as will presently be described.

"Take spirits of wine four ounces, oil of vitriol and turpentine, of each two ounces, white wine vinegar or verjuice, six ounces."

Or take the following:

"Take spirits of wine rectified four ounces, camphor half an ounce, vinegar or verjuice six ounces, white vitriol dissolved in four ounces of spring water, one ounce; mixed together."

In the lower limbs the farcy lies sometimes concealed for a great while, and makes so slow a progress, that it is often mistaken for grease, or for a blow or kick; and goes by the general appellation of a humour settled there. In order to distinguish one from the other, we shall observe that a kick, or bruise, is generally attended with a sudden swelling, or a contused wound, which for the most part digests easily; the grease is also a smooth swelling that breaks out above the bending of the pasterns backwards; but the farcy begins on the pastern-joint usually with one bud, and runs upwards like a knotty crab-tree.

Very simple means has sometimes stopped it, before it has began to spread; a poultice with bran and verjuice bound round the part, and renewed once a day, will often alone succeed; and if proud flesh should arise, touch it with oil of vitriol, or aqua-fortis, an hour before you apply the poultice; for when the distemper is local, as we suppose it here, it is to be conquered by outward applications.

When the distemper grows inveterate, and resists the above method, and the vessels continue chorded, Gibson recommends the following mixture:

"Take linseed oil half a pint; oil of turpentine and nitre, of each three ounces; tincture of euphorbium and hellebore of each two drams; the soldier's ointment, two ounces, or oil of bays; oil of origanum, half an ounce; double aqua-fortis, half an ounce. After the ebullition is over, add two ounces of Barbadoes tar."

Rub this into the chorded veins, and wherever there is a swelling, once in two or three days; but if the orifices are choked up with proud flesh, or the skin so much thickened over the ulcers as to confine the matter, in either case it is necessary to make an open passage with a small hot iron, and destroy the proud flesh, after which it may be kept down by touching with oil of vitriol, aqua-fortis

fortis, or butter of antimony. A salve may also be prepared with quick-silver and aqua-fortis, rubbing any quantity of the former with enough of the latter, to the consistence of a liniment; smear the ulcers with this whenever they appear foul, and you will find it preferable to most other eating ingredients.

Our farriers after opening the buds, put in usually a small quantity of corrosive sublimate or arsenic, which they call coring out the farcy; this may answer where the buds are few, and not situated near large blood vessels, joints, or tendons: others use Roman vitriol or sublimate and vitriol in equal quantities: but let it be remembered, that many a horse has been poisoned by these medicines ignorantly used, and in too large quantities, which should be a caution to huntsmen not to suffer their hounds to feed on the carcases of farcied horses, as the greatest part of a pack have been poisoned by that means. I shall now mention some of the desperate methods, and more violent kinds of medicines given by some internally: thus from four to eight ounces of lapis calaminaris, to which two ounces of tutty, finely powdered, is added, with other metallic substances, have been given. Some give a pound of barrel soap boiled in stale beer; with favin, rue, and other herbs of that intention: others go yet further, being determined to kill or cure, by giving drinks prepared with green vitriol, roche-allum, Roman vitriol, oil of vitriol, boiled in chamber-lie, with hemp-seed, hemlock, and common salt. Those who use nothing but the decoctions of juices of herbs, such as wormwood, rue, or elder particularly, stand a much better chance for a cure, if given in time; but when the distemper is grown inveterate, nothing comes in competition with mercurial and antimonial medicines.

The following balls are proper in every state of the farcy, and when the distemper has been in its infancy, before the skin was much defaced, has often cured it in a week or two, by giving them only once or twice a day: but in an old farcy, they should be given for two or three months together.

“Take of native cinnabar, or cinnabar of antimony, eight ounces; long birthwort, and gum-guaiacum powdered, of each four ounces: make into a paste with honey, and form into balls of the size of a large walnut, and roll them into liquorice powder.”

The tediousness of this course has encouraged the giving of mercurials, and indeed, where they are directed with skill, they must be attended with success; the stronger preparations, as the red and white precipitates, and turbith, being combined with sharp saline parts, may be hazardous and injurious, but the latter given in small quantities have been found very successful in such kind of inveterate disorders. Mr. Gibson says, he has given it to a dram at a dose, where the limbs have been greatly swelled; that in forty-eight hours the sores were all dried up, and the limbs reduced; but that it made the horse so violently sick for several days, and scoured him to such a degree, that it could not be repeated.

One would have thought, that the success attending this medicine so suddenly, might have encouraged Gibson to have made further trials in smaller quantities; which, had he done, it is more than probable, he would not have been disappointed: for the grand secret in giving mercurials, as alteratives, is the introducing them into the blood, without operating on the stomach and bowels; and to do this effectually, they must be given in small quantities, and so bridled, as to controul their force on the first passages: taken in this manner, they will mix gradually with the blood and juices, and operate both effectually and safely.

The method I would recommend is as follows: give one scruple, or half a dram of turbith, mixed into a ball, with an ounce of Venice soap, every other night for a fortnight; then abstain a week or ten days, and repeat it again. Should this ball purge, or make the horse sick, mix it up with two drams of philonium, or with four or five grains of opium, or camphor; with these restrictions, it may be given for some weeks; but should the horse's mouth be found tender or sore you must refrain giving, till that complaint is removed by gentle purges; and then return to it again in small quantities; for as the effects of mercurials are very different in the different constitutions, both of horses, as well as men, so the quantity must be varied in proportion to the operation, which is not intended here to be visible, but to work imperceptibly on the blood and juices, correcting them as a powerful alterative. During the whole course, particular care should be taken that he gets no cold.

Two ounces of quicksilver, divided with an ounce of

turpentine, and made up into four balls, with diapente, and gum guaiacum, of each two ounces, and a sufficient quantity of honey, have, for this purpose, been successfully given, one ball twice a week; but gentle purgatives should be interposed, to prevent a salivation, which some horses are very prone to, on taking mercurials, though in small quantities.

Dr. Bracken recommends the knots and chords to be rubbed with the mercurial ointment before they break, in order to disperse them, and, after breaking, to dress the sores with equal parts of Venice turpentine and quicksilver: if by these means the mouth should become sore, treat as above. This method seems to be effectual with proper care.

The following is also recommended by the same gentleman.

“Take butter of antimony, and bezoar mineral, of each an ounce, beat up with half a pound of cordial ball, and give the bigness of a walnut, or three quarters of an ounce every day, for two or three weeks, fasting two or three hours after it.”

As most preparations from antimony are of use in the farcy, so from two drams of antihecticum poterii to half an ounce, may be given with a bit of cordial ball every other day, for some time; for in these obstinate cases the very crisis of the blood must be altered, which can only be affected by degrees, and of course is a work of time. *Bartlett's Farriery*, p. 178.

Water-FARCY. See the article WATER-FARCY.

FARDING-BAG, the first stomach of a cow, or any other ruminating animal.

FARE of pigs, the number a sow bringeth at one time.

FARM, a portion of ground cultivated either by the owner or a tenant.

The ancient writers of husbandry, who lived in warm countries, where the heat and moisture of the air had sensible and frequently very dangerous effects on the health of the inhabitants, were very particular in their directions, for the choice of farms or estates, and of the spots whereon houses should be built, so as to avoid the inconveniences arising from the climate, or from the quality or situation of the ground.

Though the temperate air which we enjoy in this island renders such directions less necessary here, yet as several places in it are remarkably sickly, and as, even in the most healthy situations, many houses and villages are built upon the least healthy spots, it must be of considerable advantage to those who can make their choice, to know what soils and places ought to be avoided; and of such as are already fixed, to be acquainted with the means of correcting these inconveniences which cannot be totally remedied.

Instructions of this kind are now full as necessary in our language, as they were ever in the Greek or Latin, the countries in which English is spoken being more extensive, and more various in their climes, than even the Roman empire was.

The sacrifices of the ancient Romans shew how attentive they were even in the choice of the ground they encamped upon: much more were they so in that of the situation and nature of the place where they laid the foundations of more lasting buildings. They examined the livers of the cattle fed on the spot, when they offered them in sacrifice; and if these were livid or corrupted, they offered others, as the unsoundness of the first might be owing to some casual distemper: but if they were often found to be morbid, they concluded that the air, water, or food, which the place yielded, would have a like effect on human bodies, and therefore speedily left that ground, to search for a better situation. If after repeated trials, they found the livers good, they judged the air and food to be so likewise, and settled accordingly. We may still observe the good effect of this precaution, in the healthy situations of the remains of Roman encampments: for they preferred health to every other consideration.

The Romans had pleasure as well as profit, in view, when they bought or stocked a farm; and therefore they laid it down as a rule, that no degree of fertility should tempt a man to purchase in an unhealthy country, nor the pleasantest situations in a barren one. “Buy not too hastily,” said the wise Cato, “but view again and again the purchase you intend to make; for if it be a good one, the oftener you see it, the better it will please you. Examine how the neighbouring inhabitants fare. Let the country it lies in be a good one; the ways to and from it good;

good; and the air temperate. Let your land, if you can choose your situation, be at the foot of a hill, facing the south, in a healthy place, where a sufficiency of labourers, of cattle, and of water may be had. Let it be near a flourishing town, the sea, or a navigable river; or bordering upon a good and well frequented road. Let the buildings upon your ground be strong and substantial. Do not rashly condemn the methods of others. It is best to purchase from a good husbandman, and a good improver."

Besides the healthfulness of the situation, three other things should be particularly attended to in the choice of a farm or estate; these are the air, the water, and the soil. The air should be pure, and temperate; the water wholesome, and easily come at, and the soil rich.

The knowledge of the healthiness of the air is, as lord Bacon observes, discoverable rather by experiment than by reason or conjecture.

To examine the moisture of the air before a house is built; wool, or a sponge, may be hung up in the place, and afterwards compared with some of the same, exposed in the same manner, and at the same time, in another place. According as they gain more or less in weight, the air is more or less humid.

The air is liable to greater alterations, from heat and cold, in some places than in others; and as that inequality in the air, is an enemy to health, the most equal should be chosen. This is easily determined by the thermometer, and by viewing the situation of the place; for the intermixture of hills and vallies, though pleasing to the eye, may be held suspected as to the lengthening of life, because of the variations of heat and cold.

Open places and champaign countries are judged to be healthy, where the soil is dry, not parched, or sandy, where wild thyme and other oramatic plants grow spontaneously, and which is not otherwise bare, but interspersed with trees for shade. Yet the change of air in travelling, after being accustomed to it, is healthy: whence many travellers have proved long lived; as, indeed, have also such as have dwelt constantly in the same cottage. A ruddy complexion, clear white of the eye, quick hearing, and distinct voice, are set down by Palladius, as marks of the healthfulness of the place where these circumstances are met with in the generality of its inhabitants.

The ancients are particularly attentive to the quality of their water, and to the ease of coming at it. They advised bringing into the farm-house the water of a spring which never dries up; or, if there be no such spring within the farm, to bring running water as near to it as may be; or to dig for well-water, not of a bitter or brackish taste. If neither of these was to be found, they directed large cisterns to be provided for men, and ponds for collecting and retaining rain-water for cattle. They esteemed that running-water to be best for drinking, which had its source in a hill; spring, or well-water from a rising ground, was deemed the next best; well-water in the bottom of a valley was held to be suspicious; and marshy or fenny-water, which creeps slowly on, was by them rightly looked upon as the worst of all.

That water is known to be wholesome, which has no mineral in it, is perfectly clear, has not taste or smell, deposits no slimy sediment, leaves no spots, or incrustation when boiled in copper or brass vessels, and which boils pulse in a very little time. "Rain-water, says sir Thomas Elliot, in his Castle of Health, is the most subtle and pure of any other water. The next is that which issueth out of a spring facing the east, and passeth swiftly among great stones and rocks. The third is of a clear river, which runneth on hard stones and pebbles. There be divers means to try which is the best water; for that which is lightest in poise or weight, is best; also that whereof cometh least scum or froth when it doth boil; also that which will soonest be hot. Moreover, dip linen cloths in sundry waters, and afterwards lay them to dry; and that which is soonest dry, the water wherein it was dipped, is most subtle."

As springs and well-water pass through beds of sand, gravel, or small stones, these clear it of all impurities, unless there be mixed with them substances which are soluble in water. If any mineral is mixed with the water, it is unfit for the farmer's use. If it be hard, it is thereby rendered unfit for washing, and some other culinary uses. This is the kind of water which gives flesh boiled in it a red colour. But even the hardest water may be easily rendered perfectly soft, and fit for any use, by mixing with it a

small proportion of pot-ash, fixed salt, or, for want of these, the ashes of any burnt vegetables.

The animal and vegetable substances which are mixed with stagnating water putrefy, and taint that water. This taint is most effectually carried off by boiling, during which all the putrid particles evaporate: and whatever else remains in it will subside when it is cold. It may likewise be much mended by having air forced through it by means of Dr. Hale's ventilator; or it may be corrected by mixing with it acids, such as vinegar, juice of four fruits, spirit of nitre, vitriol, &c.

When there is neither running nor spring-water, artificial springs may be made in the manner thus pointed out by lord Bacon, who does not indeed say that he had experienced it himself; but it has been repeatedly tried since his time, and found to answer very well: "Upon a hanging ground, where there is a quick fall of rain-water, lay a half trough of stones, of a good length, three or four feet deep in the ground, with one end upon the high ground, the other upon the low. Cover this trough with brakes, to a good thickness, cast sand upon the top of the brakes, and you will see, after some showers are past, the lower end of the trough run like a spring of water." This will continue for a long time after the rain is past, "as if, says that great philosopher, the water did multiply itself upon the air, by the help of the coldness and condensation of the earth and the consort of the first water." A gentleman in France, whose mansion stood on a height far from any water, was advised to make a long ditch, about a fathom deep, in the neighbouring higher grounds, and to fill it with sand; he did so, and it continued to bring a plentiful supply of water, for all domestic purposes.

M. de la Hire observes in the Memoirs of the Academy of Sciences for the year 1703, that rain-water which has been purified by passing through clean sands, and is afterwards collected in subterranean reservoirs, will keep a long while without becoming putrid. He thinks this water the best that can be made use of, either for drinking, or for other oconomical purposes, because it is not impregnated with any mineral, as spring waters sometimes are. The only thing requisite in the construction of such reservoirs or cisterns is, to have a place which will hold water, made of such materials as will not communicate any bad quality to the water, which is to remain there a considerable time. The first water that falls from the roofs of houses when it begins to rain, should be thrown away; as having served only to wash the roof, which, in dry weather, is always covered with dung of birds, and other filth. He rejects snow-water for the same reason; and likewise the water of rain brought by winds which pass over places infected with ill smells, as large cities, links, &c. He computes, that water enough for the use of any family runs off the roof of the house which is inhabited by that family.

The buildings on the farm should be proportioned to the produce, especially as to store-rooms. The expence of building should be such, as that, in case of accidents, one, or at most, two years rent may repair them. The farm-house should be somewhat elegant, to give pleasure to its possessors, and, as Columella adds, to allure the wife to take delight in it. It should be built on the most healthy spot of the farm, in a temperate air, such as the middle of a hill commonly enjoys, where it is neither stifling in the summer, nor exposed to the rage of winds and storms in the winter. It may be seated near a quick running river, if the banks are high, and the channel clear of mud; but if the river is large, care must be taken to situate it so that the winds may carry off the vapours in summer, and the fogs in winter, which otherwise would prove hurtful to the health of men and cattle. The front of the house should be turned from such a river. In a healthy situation, a house should front the south east, which is shaded during the hottest part of the day in summer, and enjoys the morning sun in winter. A house facing westerly will have the morning fogs longer retained, and will be too much heated by the afternoon sun. In an unhealthy situation, the front should be turned toward the north.

In southern climates, where the sun is within a few degrees of being vertical in summer, and yet the country is subject to severe cold in the winter, as is the case of some of our North American colonies, a south front is rather convenient: for in the heat of summer, the sun, being high, passes over the roof from the east side to the west, and

and shines but little, or not all, in at the front windows, and very weakly, because obliquely, upon the front wall. But in the winter, being low, it shines full in at these windows, at a time when the cold renders its cheering presence quite agreeable.

Places in this kingdom intended for defence, before the invention of cannon, were built either on rising grounds difficult of access, or where they could easily be secured by moats filled with water. Villages and farm-houses were most frequently built in vallies, that they might be sheltered from stormy winds; or near brooks or rivers, for the conveniency of water. In general, every means have not been used to provide against the inconveniencies of these situations: though as Mr. Worlidge observes, "were we for the future but duly to observe the best situations of places, and the compleatest methods of building, in such houses as may hereafter be raised, our England would in a few years appear a kingdom beset and adorned with curious and admirable habitations, possessed by noble and ingenious inhabitants."

Houses built on too lofty a situation are exposed to the violence of the winter's storms, and to the scorching drought of the summer: yet we too generally find them without the only shelter their situation admits of, which is wood. The reason of this seems to be, that the inhabitants, finding that trees do not thrive well when they are first planted on dry heights, are at once discouraged. But where the plants are fenced from nipping winds while young, and protected from cattle till they become strong, such ground would be found abundantly favourable to the growth of trees which delight in a dry soil. "These, as Mr. Worlidge expresses it, would yield a cooling, refreshing, sweet, and healthy air and shade during the heat of summer, and very much break the cold winds and tempests from every quarter in winter."

One might be apt to think from the unhealthfulness of low and fenny countries, that moats full of water about houses should be prejudicial to health: yet many facts shew the contrary. In Numb. 310, of the Philosophical Transactions, a particular instance is given of two parishes which were surrounded with a morass, and yet were very healthy. Many houses surrounded with moats are drier than others in a seemingly better situation; for books and furniture are often less apt to grow mouldy in the former, than in the latter. Hence it would seem probable, that the unhealthiness of low marshy countries must arise, rather from the putrefaction of animals and vegetables in slow, moving, or stagnating waters, than from a too great moisture of the air, occasioned by the quantity of water evaporated. Of this Dr. Pringle gives a remarkable instance in his judicious and useful Treatise on the Diseases of the Army, when he says: "Another cause of the moisture and corruption of the air where the inundations made about the fortified towns since the commencement of the war; which were particularly noxious upon letting the water off in the beginning of the summer, after the preliminary articles of the peace were signed. For these grounds, which were once entirely covered, being now half drained and marshy, filled the air with moist and putrid exhalations. The states being made sensible of this, by the sickness that raged at Breda, and the neighbouring villages, gave orders to let in the water again, and keep it penned up till winter."

All physical writers point out the great danger to which health is exposed from a moist and warm air; especially if it be attended with a putrid vapour. Too much care cannot therefore be taken to guard against both. The too great moisture may probably be prevented by collecting all the waste water into deep ditches or ponds. We frequently see that ponds which have no supply of water but from rain, retain water during a very dry summer, when, according to the usual calculations of evaporations, the whole must have disappeared in half the time; from whence it seems more than probable, that the quick evaporation of water, in some cases, must arise from a heat reaching to, or affecting the earth under the water; and that, if care be taken to make the ditches or ponds so deep that the heat of the sun shall not warm the earth at their bottom, the quantity evaporated will be but small, and such will not be prejudicial to the health of the neighbouring inhabitants, if neither animal nor vegetative bodies are suffered to rot in them. The way to prevent this is by keeping the water free from grass, or other impurities, which may give shelter to animals, whose rot-

ting, as well as that of the grass, or of those impurities, communicates a putrid taint to the exhalations. It is in this case necessary, that the banks of ditches, or ponds, be sloped as little as the strength or stiffness of the earth will permit.

Though lofty and bleak situations are too often destitute of trees, villages built in vallies are as frequently too much crowded with them; which must be attended with the inconvenience of not having a free circulation of air, to carry off the moisture arising from the earth, and perspiring from so many trees. The ancients would have built such villages on rising grounds, to avoid the too sultry heat of the summer; or they would have preserved a free circulation of the atmosphere, to prevent the bad effects of a stagnating moist air.

On the first settlement of the English in North America, they imitated our custom of building in vallies, and near rivers; but experience soon taught them, that such places are more subject to the suffocating sultry heat of the summer, and, what they little expected, to a greater severity of frost in the winter, than rising grounds generally are. We have been informed by one of the most curious and intelligent observers of the laws of nature, of perhaps any man on that continent, that the cold there, in their hardest frosts, is found to be so severe in the vallies, to a certain height, as sometimes to kill every tender vegetable, while those on the higher grounds escape. This generally takes place to a regular determined height, above which the Americans now build their houses. If we be allowed to offer a conjecture concerning the cause of this, we should say, that the effect of the cold seems to be limited to the height to which the great moisture of the air arises at that season. In the hard winter of 1739-40, the same happened in this kingdom, when the frost was much less severe in its effect in the hilly countries, than in the low lands.

Dr. Pringle, in his excellent treatise before-mentioned, points out the disadvantages of planting so many trees as there generally are in most parts of the Netherlands. The same practice may be as justly blamed in many of the flat moist countries in England; especially where they border on marshes. Their speedy growth tempts the inhabitants to plant, at the side of their ditches, willows and other trees, which delight in a moist soil; and these not only prevent a free circulation of air, but also perspire a great deal of moisture. Dr. Pringle confirms this by the following instances.

"At Eyndhoven, two battalions of the guards were quartered in the town, and the third lay without, in the peasants houses, all within the compass of a mile; yet what was remarkable, this without the town had always three times more sick in the returns, than either of the other two, notwithstanding one of them had been very sickly the year before in Zealand. Now, the height of the ground being alike in all, the difference in point of health could be ascribed to nothing, but to the greater moisture of the cottages; for in all other points, these corps were equal as in diet, duty, and exercise. A similar case occurred in the cantonment of a regiment of foot, whereof one company being quartered in houses that stood upon a heath, enjoyed a tolerable degree of health, while the rest that dwelt in a wood were remarkably sickly. As a further proof how prejudicial it is to have the air confined by close plantations in so moist a country, it was observable, that the Dutch camp at Gilsen, bordering on our cantonment, but lying on an open heath, preserved a good share of health, while we were at the worst. It was not a little curious to observe, how the agues declined proportionably with the withering and falling of the leaf. At this time less moisture ascends, and by the shedding of the leaves, villages come to be more open and perslated, and of course more dry and healthful. While the troops were very sickly in Zealand, commodore Mitchel's squadron, which lay at this time at anchor in the channel, between South Beverland and the island of Walcheren, in both which places the distempers raged, was neither afflicted with fever or flux, and amidst all that sickness enjoyed perfect health: a proof that the moist and putrid air of the marshes was dissipated, or corrected, before it could reach them; and that a situation open to the winds is one of the best preservatives against the maladies of a neighbouring low and marshy country."

The driest spot in a low, flat, or fenny country should be chosen for a dwelling place. Even where there is gravel

or sand on the surface, care should be taken that the springs do not rise high. Dr. Pringle points out the necessity of this caution, from what he observed in the lower parts of Brabant, "which is a barren sand, where so little water is seen, that, at first sight, the country is deemed dry and heathful: but the appearance is deceitful; for water is every where to be found at two or three feet from the surface: and in proportion to its distance from thence, the inhabitants are more or less free from diseases."

Mr. Worlidge directs, that, in low, moist grounds, cellars should be made under the house, with good ceilings, or rather arched walls; for that this will conduce much to its dryness and healthfulness. The importance of rendering houses dry appears in many instances mentioned by Dr. Pringle: but we shall give only that in his twelfth page. "One quarter of Ghent, called St. Peter's-hill, stands high above the rest of the country; and in this, the barracks, having drains and free air, were quite dry; so that the men who lay there enjoyed perfect health. But the rest who were quartered in the low part of the town, where their barracks were mostly the ground-floors of waste houses without drains, and of course very damp, were all sickly."

The bed-chambers, in such situation, more especially, should be in the driest and most elevated part of the house, and where the morning sun may contribute most to keep them dry. If they are so situated, that the sun does not warm and dry them, they should be frequently aired with fires; the oftener in proportion to the greater dampness of the place: for this has been found to contribute greatly to the health of the inhabitants. We are informed by a gentleman who has experienced it in many instances, that, by this sole precaution, he has preserved several families from the ague, when that distemper was very epidemic in the neighbourhood. How much the dryness of bed-chambers contributes to health is confirmed by what Dr. Pringle observes to have happened at Bruges, where the soldiers that lay in the upper stories kept their health remarkably better than those who were below on the ground floors.

As brick walls render houses drier than those of stone, and of a more equal warmth than plastering, Mr. Worlidge directs, that, "where bricks can be had, the walls should be built with them, as may be done with little cost, if you raise firm and strong columns at the corners of the house, and where it is necessary to support the main beams. You may build these square, and between them raise the walls with the same materials, and work them up together with the corners and columns, leaving one half of the extraordinary breadth of the column without, and the other within the walls, whereby you will save much charge in materials and workmanship, and yet your house will be firm and strong."

We are too little attentive to the situation of houses with regard to rivers; though a judicious choice in this must be of great consequence to the health of the inhabitants. A quick flowing stream, with clean channel and dry banks, will rather add to the beauty and healthiness of a country; but oozy banks, over-run with reeds or other strong coarse grass, should be carefully avoided, as being a shelter to all manner of putrid filth, whence unsalutary vapours must arise. It is a general opinion, that it is safer to dwell on the north than on the south-side of a river; but experience seems to prove the contrary, especially in warm climates. Marshes, which are sometimes overflowed with salt water, are found to be more unwholesome than fresh water marshes. Their neighbourhood should, therefore, be carefully avoided.

The Romans were universally agreed, that it was much better to occupy a small farm than a large one; and laid it down as a rule, that the farmer ought to be stronger than the farm; because in the struggle which will arise between them, if the farm be too strong for the farmer, he must be ruined; that is, if the extent of the farm be such that he cannot bestow a due culture on every part of it, he must be a loser: for, as Columella remarks, "it is certain, that a large tract of land, not rightly cultivated, will yield less than a small space well cultivated."

A judicious correspondent of the editors of the *Museum Rusticum* rightly observes, that the stocking of a farm is a point of great importance, and requires as much judgment and foresight as any other point in husbandry.

"The bad success of great numbers, continues he, is owing to their not having a sufficient sum of money to begin with, which inevitably involves them in difficulties, and reduces their profit on every article of their produce. Their farm is understocked; they sell at a constant disadvantage; their fields are not half cultivated; and in a short series of years, unless some lucky hit sets them up, they grow poor, in spite of all possible industry, judgment, and application.

"Even a low and easy rent will seldom remedy the want of money at setting out.

"The want of judgment, in proportioning the quantity of each particular kind of stock to the quantity and nature of the lands of a farm, is also attended with great loss.

"For instance if a farm requires four horses, or two ploughs, and the farmer keeps only three, or a plough and a harrow, his fields cannot be sufficiently cultivated, even according to the ideas of culture common among farmers; and of course in a few years his lands must be in very bad order, to his great annual loss.

"On the contrary, to overstock himself with horses, is to keep what will inevitably eat him out of a house and home: expences attending them are very great, and if they are not kept constantly at work, their owner must necessarily lose by them. But it will not be amiss to explain myself more particularly on this head.

"I am speaking at present of the practice of farmers, some of whom overstock themselves with horses, without giving their lands extraordinary stirrings on that account. If a farm, which commonly requires three horses, has four kept, and is consequently ploughed and harrowed proportionably more, the farmer will be no loser by his fourth horse; but the case is very different when he is kept without being worked to the best advantage of the farm.

"It is not to be at once perceived how much is lost by not having the number of horses proportioned to the land; nor can this always be done.

"A farmer may find it necessary to keep four horses, and when he has got them, it is a chance but he could perfectly well manage several fields more with them; and when a man has an opportunity of hiring additional fields, then should his judgment come into play, to take no more than his old stock will manage to advantage, unless he has a sum of money ready to make an addition to it.

"The same ill consequences attend either over or understocking a farm with all other cattle: and it would be the farmer's advantage was he always to remember, that three beasts, of any kind, well fed, pay better than four without their bellies full. On the contrary, not to keep the stock necessary, is to submit to a constant loss. Both these sorts of conduct are frequently followed, to the great unprofitableness of farming.

"The proportion of the pasture and arable lands of a farm is of great consequence towards the occupier's making a profit of his business.

"The unprofitable practice of ploughing up pastures, and not laying them down again, which is so universal in this country among farmers, whenever their landlords will allow it, tends perpetually to impoverish them. They are all, to a man, mad after ploughed lands, and would willingly break up every acre of grass in their farms.

"So general an opinion among them would make one think the practice really profitable; but the contrary appears beyond all contradiction to be the truth; I mean, according to the culture at present pursued in this country.

"Two thirds of the land of a farm in a rich country should be grass; and a little one had better all be so. The vast expences of the plough, without doubt, keep many farmers poor, who, if their farms were grass, would not run half the hazard, and enjoy a much better income.

"Particular points of bad management, for want of sense or knowledge, through slovenliness, idleness, or other obstructions, to any profitable husbandry, are not what I mean to speak of here, since they are so very various, and so totally ruinous, that no reasoning can be conclusive, unless all such exceptions are made.

"The improper quantity of land in a farm is often against the farmer's profit.

"Very large tracks, of two or three thousand acres, which

which are common in Norfolk, are too extensive for one farm. It is impossible for one man to cultivate such a quantity of land well: much of it must be neglected, and but little perfectly managed.

"Great profit, indeed arises from most of these farms; but they take a very large sum of money to stock and manage them properly.

"Very small ones, unless the farmer does the whole business himself, are equally liable to objection. The medium, which is ever in proportion, the most profitable, is that quantity of land which will admit of being stocked and farmed without the want either of any addition or diminution. What I mean is this:

"Let us suppose a farm to consist of seventy acres of land, twenty of them grass, and the rest arable, in a rich country, the land from ten to sixteen and seventeen shillings *per* acre; the occupier must keep one servant, and if he does not work hard himself, one labourer all the year, besides some additional help at busy times.

"I know there are many slovenly men, who cultivate (if their management deserves that name) such farms with fewer hands than I have mentioned; but their conduct can be no rule to good farmers. Four horses are also necessary for such a farm.

"Now, for the same standing expences of servants wages, horses, &c. the same number of ploughs, harrows, tumbrils, waggons, &c. &c. one hundred acres, or better, might be farmed with the same proportional profit: in this case, therefore, the tenant of seventy acres loses considerably for want of thirty or forty more. Indeed, we seldom meet with a farm nicely proportioned to the stock on it.

"There are many very evident reasons why farming should prove unprofitable to gentlemen who undertake to cultivate a part of their estates, whether for their amusement or convenience, or, generally speaking, even for profit.

"A very fine Norfolk farm, of a large extent of country, the rent exceeding low, and a gentleman willing to be at the expence of marling, in such a case, there is no fear of a considerable profit, even without perpetual attention: but in common farms, in rich countries, no profit can arise to any gentleman that does not give the business constant attention, and descend to *minutiæ*; which may be too disagreeable for him to submit to.

"What I mean by profit, is not making the rent which he might receive from the tenant without trouble, and without hazard; but that additional sum which is the farmer's profit after his rent and all expences are paid. This is scarcely ever made by gentlemen, who farm either for convenience or amusement; and, excepting grass grounds, I am persuaded they lose considerably by keeping land in their hands. The plea of growing enough for family use of wheat, oats, &c. is a mistaken one; they had better by far buy every article, than have any thing to do with the plough.

"When I am told that farming answers to gentlemen, who I know do not give the farmer's attention to the business, I never believe it, or, at least, am persuaded that no regular accounts are kept. It will not be difficult to produce some good reasons for this incredulity.

"It should be remembered, that the farms which gentlemen keep in their own hands are seldom above fifty, sixty, seventy, or an hundred a year, and not often so much. It is no easy matter for a farmer, with industry, sobriety, and application, to make above a rent profit in such a farm; and I believe but seldom so much. This is, with every advantage of understanding his business, applying close to it, and doing some work (if his farm is small, a great deal) himself: how unlikely is it therefore that a gentleman, who may probably want these advantages, should make near that profit, or, indeed, any at all!

"In the first place, a principal part of his business, his buying and selling, is transacted by his bailiff, or head servant, who must be paid for his trouble. He may be lucky enough to meet with an honest one; but I would never advise any one to let the profit of his farming depend on the honesty of other people. Suspicion, to the open generous mind, is irksome and grating: but the farmer should set out with the maxim of Descartes—to doubt of his very existence, and suppose every man a knave till he finds him honest.

"But there are many inconveniencies, besides these, in trusting to bailiffs.

"The gentleman we must certainly suppose to be ignorant of farming; and he is then, of course, in danger

of having an ignorant servant, without the ability of detecting him. However, the single expence of a bailiff, or a head servant, which are much the same, is too great to be kept constantly for a small farm; and in their absence the gentleman must depend on himself.

"This is palpably no dependence at all; for can it be expected that he will forego his diversions, his excursions of pleasure, the company of his friends, the joys of society, to attend to his farm? I could almost as soon believe, that his wife would renounce an opera or a ball for the pleasure of dancing attendance on her butter and cheese in the dairy. The rural joys of romance are pretty much out of date now; and, alas! there is a great difference between the employment of a farmer's wife in England, and keeping sheep in the plains of Arcadia.

"But to return:

"There are, even in a small farm, a thousand objects which require constant attendance.

"Cattle of no kind will thrive but in the master's eye: every variation of the season to be remarked; the lucky moment for ploughing, harrowing, sowing, reaping, &c. to be caught, and used with diligence and foresight; fences are for ever to be attended to; and, in short, a million of other things, which require constant thought and endless application.

"That single article, the employment of labourers, will alone run away with the profit of the whole farm.

"But surely it appears plainly, from what I have said, that the unprofitableness of farming is scarcely ever owing to the art itself, but to the mistakes of those who practise it.

"As I have been so particular in distinguishing several points by which the followers of it lose, I shall now trespass a little longer on your patience, and give my sentiments on the custom of gentlemen's farming, in other respects than that of profit, to those who are not solicitous about it, and in relation to it, to those whose fortunes will not allow an indifference to such a point.

"It is scarcely possible for a gentleman to live in the country without finding many inconveniences in not keeping a team of farming horses, with waggons, carts, &c. and other implements used in the business of husbandry. While profit is not considered, there will flow a multitude of agreeable circumstances from farming, which will have some relation to almost every particular of a country life.

"In respect of entertainment, what more rational, or more amusing, than country business, without the anxiety of caring for profit! The public good calls loudly to all gentlemen to keep some land in their hands, that experiments may be made, and modes of agriculture pursued, different from the practice of the neighbourhood, for the farmers, at least, to see that their own customs are not the only good ones, and that there are improvements to be made even on their practice.

"All the improvements and new inventions in agriculture come from gentlemen; scarcely one, that I ever heard of, is known to have been discovered by farmers.

"I do not wonder at this; for I think it is natural enough; but the same time, it is a strong reason for gentlemen's farming, whether they make profit by it or not. The extensive use of manures, and introducing a garden culture into the field-husbandry, were the effects, among a hundred other instances, of gentlemen's farming.

"But if the public good was not to be considered, yet the mere amusement of farming to a gentleman of fortune, who has the least taste for country business, must plead warmly for its practice. Such farmers soon make a garden of their estates, at the same time that they improve the value of them.

"What can be more amusing than experimental agriculture? trying the cultivation of the new-discovered vegetables, and all the modes of raising the old ones; bringing the earth to the finest pitch of fertility, and growing plants infinitely more vigorous and beautiful than any in the common tillage; using the variety of new machines perpetually invented, and observing their effects; and, in a small extent of ground, see the growth of an infinite variety of vegetables, unknown in the common practice; perpetually enjoying the neatness of husbandry, that *simplex munditiis* of farming, which gives the most beautiful colouring to every object around, and pleases the refined imagination with the enchanting prospect of all the elegance of nature.

"Those

"Those gentlemen of small fortunes, who if they practice any thing of farming, find it necessary not to be indifferent to profit, have many points to consider.

"Such a one should remember, that though a farm will afford amusement, it will not yield profit without application. A constant attention to every article is highly necessary. He should keep the exactest accounts, and make memorandums of what knowledge he can pick up. For a few years he must employ a bailiff; and he will find that every day and hour will increase his own knowledge, if he is attentive to business." *Museum Rusticum*, vol. IV. p. 264.

Mr. Marshall, in his Minutes of Agriculture, remarks, that public paths are nuisances of arable land. Fields of various soils are very inconvenient. Small stragling fields are extremely disadvantageous on a plow farm. Incontinuity of arable land, robs the farmer of both pleasure and profit. It is inconvenient to have more than one farm yard. If incontiguous arable land be foul and poor, it is barely worth the labour of cultivation. An adjacent common is highly advantageous. Wet land is the bane of farming. It is very unprofitable to hold farms under different landlords. There are many advantages of a ring fence farm. There are great advantages as well as disadvantages, in farms of various as well as in those of uniform soils. A dry loam, culturable by whip-reins, is a most desirable farm. A compost-farm requires more team-labour than a folding-farm. He concludes his remarks with, "do not add farm to farm," he then adds, "dung-yards ought to receive no extraneous water; barn-room is particularly useful in a showery harvest; a distinct chaff-house relieves the barn-floors; and granaries should always be situated under the farmer's eye."

We shall conclude this article with the following

"*Prices of Implements of Husbandry, Corn, and Farming-Work, in the North Part of Hertfordshire, about Hitchin, Baldock, and Stevenage.*

- A waggon complete, from 16 to 20 l.
- A cart complete, from 8 to 10 l.
- A two-wheeled plough complete, with draught-chain, and splinter-bars, or whipple-trees, 3 l.
- A wheat two wheeled sowing-plough, as the same wheels serve for both, 1 l. 1 s. 6 d.
- A foot, swing, or dray-plough complete, 1 l.
- A roller complete, 15 s.
- A five-barred harrow ditto, 17 s.
- A four-barred harrow ditto, 15 s.
- A three-barred harrow ditto, 12 s.
- First ploughing per acre, 6 s.
- Second ploughing per acre, 5 s.
- Harrowing per acre, 6 d.
- Rolling per acre, 4 d.
- Hoeing turnips per acre, 4 to 5 s.
- Hockling, or cutting up and raking haulm, 2 s 6 d. per acre.
- A harvest-man has per month from 33 to 40 s. and his diet.
- A ploughman, for a day's work, 8 d.
- A labourer, 1 s. per day, and small beer.
- Price of threshing per quarter, wheat 2 s. barley 1 s. oats 9 d. pease 1 s. 4 d.
- Price of horses, from 5 to 15 l.
- Price of cows, from 3 to 8 l.
- Price of sheep, from 10 to 20 s.
- Hogs, from 5 to 40 s.
- Wheat per load, 30 to 35 s. Five bushels make a load, and eight loads, or forty bushels, a waggon-load.
- Barley, 24 s. per quarter.
- Oats, 16 s. per quarter.
- Pease, 17 s. per load.
- Thatches, or vetches, 25 s. per load.
- Malt, 4 s. 6 d. per bushel.
- Note. Our bushel is nine-gallon measure.
- Turnip-seed, 3 d. per pound.
- Red clover-seed, 4 d. per pound.
- Trefoil-seed, 2 d. per pound.
- Cinquefoil seed, 4 s. per bushel.
- Wheat-straw, 10 s. per load.
- Barley and oat-straw, 6 s per load.
- Cinquefoil-hay, per hundred, 2 s. 6 d.
- Clover-hay, per hundred, 2 s. 6 d.
- Thatching per square, yelning and serving included, 2 s. 6 d.

A carpenter per day, 1 s. 8 d.

A bricklayer ditto, 1 s. 10 d.

Brick at the kiln, 17 s. per thousand.

Plain tiles, 17 s. per thousand.

Pan-tiles, 10 s. per hundred.

Lime, 6 d. per bushel.

Tiling-lath, 2 s. 10 d. per bunch.

Plastering-lath, 1 s. 5 d. per bunch.

Hurdles per dozen, 8 s.

Faggots, from 6 to 16 s. per hundred.

Making, plashing, and laying live-hedges, and ditching, 4 d. per pole of sixteen feet and a half." *Museum Rusticum*, vol. IV. p. 78.

FARM-YARD, the place adjoining to the farm-house, where cattle are foddered, and several other necessary works, belonging to the farm, are performed.

FARTHING-DALE, or *farding-dale*, the fourth part of an acre of land, now generally called a rood.

FATHOM, a long-measure containing six feet.

FATTENING CATTLE *on grains*. Mr. Marshall, in his Rural Economy of the Midland Counties, says, "that at Burton, several hundred head of cattle, mostly cows, are annually fattened with hay and grains, the produce of the brewery of Burton ale; which being brewed of singular strength, and, in the ordinary practice, little small-beer being made after it, the grains are of a very superior quality. They are mostly used fresh from the vats; sometimes warm, but never hot. When a redundancy happens, the overflowings are laid up in casks and bins covered up with mould. With these stale grains, malt-dust is generally mixed. The usual quantity of fresh grains, a bushel a day; with about half a hundred weight of hay a week. From five to six months is reckoned a moderate time for lean cows to get good meat with this keep." Mr. Marshall also recommends turnips for fattening cattle.

Mr. Young, in his Annals of Agriculture, vol. III. on the subject of fattening cattle, observes, that, "to take hogs half fat, from corn, and put them to potatoes, without checking their progress in the least, is quite a new discovery of Mr. Le Blanc's, and proves the value of it too clearly to admit a doubt. Does not this remarkable fact bring the recollection of another similar one, that of bullocks put lean to turnips doing very badly, but going on rapidly when put half fat to them? thus connected, these facts seem to suggest a general rule applicable to all animals, and totally contrary to all common ideas, which have hitherto directed to improve the food of a fattening animal as he advances; to give him the worst first, then better, and the best at last. The contrary it should seem, ought to be the mode: first to get the hog or bullock half fat as fast as you can with the best food you can give him, and then he will go on and thrive upon any food. Let me observe, that I have often remarked in my own farm yard, that beasts put from grass to straw (and sometimes bad straw) which have been in very good order, have thriven and kept to their looks infinitely better than others that came in quite lean and poor; but according to common notions, the former should fall away upon the change, which is contrary to fact. But let us carry the idea still further, and see if these facts thus connected do not seem to unite with another seemingly very different one. It is Mr. Bakewell's system (and I believe a very just one) that a well made animal, which shews in his form a disposition to fatten, will thrive better upon the poorest food, though changed to such food from better, than an ill made poor animal that never knew any better."

FEABES, or *feaberries*, gooseberries.

FEBRIFUGE, having the power of curing fevers. See FEVERS.

FEBRUARY, the second month of the year.

This is a principal seed month for such as they commonly call lenten grain, and is usually subject to much rain or snow, which is not unseasonable.

Now sow all sorts of grey pease, fitches, beans, and black oats: in dry weather carry out dung, and spread it before the plough, and also on pasture ground: this being the principal month for that purpose.

This is a very proper time for planting trees and quicksets, and also to plash them; to set willows, plants, or pitchers, and also poplars, osiers, and other aquatics; and to lop trees, or cut coppices.

Sow mustard-seed, and hemp-seed, if the spring prove mild: feed your swans, and make their nests where the floods cannot reach them.

Soil such meadows as you cannot overflow, or water; catch

catch moles, and take great care of ewes and lambs where they are forward. *Mortimer's Husbandry*, vol. II. p. 413.

FEED, the quantity of oats, &c. given to a horse or other animal.

FEEDING of cattle. See the article **CATTLE**.

FEET, the bases or supports of an animal.

The knowledge of the feet is of the utmost importance in purchasing a horse. Nor is it enough that the creature have a well-proportioned foot; for if it chance to be thin or weak, the buyer will be disappointed in his expectations; as such a foot is liable to be spoiled in shoeing, by travelling on hard stony ground, by too much drought in hot seasons, or by too much moisture in winter. A thin foot is that where the crust or horn is thin. This may be very easily seen when the shoe is taken off, because the verge all round the sole will appear thin; and where it is so, a horse will wince with the least touch of the pincers. The heel and frog are also apt to be soft and tender to the touch, and by reason of the weakness natural to such a kind of foot, it often turns awry, and one point of the heel stands higher than the other.

FELL, the skin or hide of a beast.

FELLING, the act of cutting or hewing down.

When any tree is intended to be cut down for timber, the first thing to be taken care of is a skilful disbranching, or lopping off, such limbs, as may endanger it in its fall, many trees being frequently spoiled for want of a previous care of this kind; and therefore in very large arms, chop a nick under them close to the bole, and then meeting it with downright strokes, it will be severed without splitting. Take care also to cut the tree as near the ground as possible, unless you design to grub them up, the doing of which will be of advantage both to the timber and to the wood; for timber is never so much valued, if it be known to grow out of old stocks.

M. de Buffon has very justly observed, that the trees intended to be felled for service, should first be stripped round of their bark, and then suffered to stand and die upon the spot before they are cut. For by this means the sappy part, or blea of the tree, becomes as hard and firm as the heart; and the real strength and density of the wood has been proved, by many experiments, to be greatly increased by it.

FEN, a general name for boggy, moorish, or marshy land, generally overflowed with water. See the articles **Bog**, **DRAINING**, **MARSH**, and **MOOR**.

FEN, is also the name of a very pernicious distemper to which hops are subject. It consists of a quick growing mould, or moss, which spreads itself with great rapidity, and occasions dreadful ravages in the hop grounds. See the article **Hops**.

FENCE, a hedge, wall, ditch, bank, or other inclosure, made round fields, woods, gardens, &c.

No forest trees should be admitted into the hedges that divide fields, as their shade, and wide extending roots, are found very injurious to corn, grass, and even to the hedge itself. But in countries where, instead of hedges, the fences are chiefly made of rough flakes of stone, piled dry every one upon another, or a little earth thrown in between them, to fill up the chasms, a plantation of trees within these walls will hide their deformity, and give a warmth which cannot be expected from such walls.

The most usual way of inclosing land is with a ditch and a bank set with hawthorn, crabs, black thorn, holly, or white thorn, commonly called quick. Mr. Miller's instructions in this respect are very full, and contain among others, the following directions:

"It will be proper before planting, to consider the nature of the soil, and what sorts of plants will thrive best in it; and also what the soil is from whence the plants are to be taken: for if the ground they are taken from be better than that into which they are to be put, it will be more difficult to make them grow. Those which have been raised on the spot near the place where they are intended to be set, will always do best, if they are to be transplanted; and the next to them will be such as are taken from a nursery.

"I would recommend the white thorn, the black thorn, and the crab, for outward fences to good ground: but I do not approve of intermixing them.

"The white thorn is the best quick to plant, because it is the most easily procured, is very hardy and durable, and may be rendered the closest of any fence, by proper

clipping. It, therefore, is preferred to all others for outward fences, or for the division of fields, where they are exposed to cattle, &c. It may be raised either from sets or from seeds. The former is the most common way of propagating it: for the latter, which may very properly be sown where the hedge is intended to stand, do not rise till the second spring. The white thorn will thrive on almost any well loosened soil, except the driest gravel or sand.

"The black thorn and crab make very good fences, and are to be raised in the same manner as the white thorn: but if the kernels of apples or crabs be sown, it is best to sow the pomace with them; for they will then come up the sooner, that is to say, the first year.

"The black thorn is not accounted so good for fences as the white thorn, because it is apt to run more into the ground, and is less certain as to the growing: but, on the other hand, its bushes are much better, and more lasting, than those of the white thorn, or indeed any other shrub, for dead hedges, or to mend gaps: nor are they subject to be cropt by cattle, as the others are. The richer the mould is, the better the black thorn will prosper: but it will grow on the same sort of soil as the white thorn.

"The holly makes an excellent fence, and is preferable to all the rest; but it is difficult to be made to grow at first, and is a slow grower. However, when it does grow, it makes amends by its height, strength, and thickness. It delights most in strong ground: but will grow upon the driest gravel, even among rocks and stones. It is raised from sets, or berries, like the haws of the white thorn, and lies till the second spring before they come up. These two are best sown in the place where they are intended to stand. They should be well weeded, both before they come up, and afterwards, till they are grown to such a size as, of themselves, to kill the weeds.

"French furze will make good hedges upon dry sandy banks, where few other plants will grow; but they must be kept very clean at the bottom, and never suffered to grow too high: nor should they be clipped either in dry weather, late in autumn, or early in the spring; because the cutting of them at those seasons is apt to make them die in patches, which is irrecoverable; as no new shoots will here ever proceed from the old wood.

"Alder planted on a bank, the side of which is washed by a river or stream, will make an extraordinary fence, and preserve the bank from being undermined by the water; because the alder is continually putting forth from the lower roots, suckers, which are of great advantage where the current of the water washes away the earth.

"If there is to be a ditch along the hedge, that ditch should be at least six feet wide at top, three feet deep, and only one foot and a half over at the bottom, that each side may have a proper slope; for where its sides are dug too perpendicular, they are very apt to fall in after a hard frost, or heavy rain: and if the ditch is made narrower than here directed, it will soon be choaked up in autumn, by the falling leaves, and the growth of weeds; nor will it be a sufficient defence for the hedge against cattle.

"When the bank at the side of this ditch is to be planted with quicks, the sets ought to be about as thick as a goose quill, and their tops should be cut off within four or five inches of the ground. They should be fresh taken up, straight, smooth, and well rooted. Part of the turf taken off the surface of the ground where the ditch is to be dug, should be laid, with the grassy side downward, on the side of the ditch, where the bank is intended to be made, and some of the best mould should be laid upon it, to bed the quick. The sets of quick, prepared as before directed, are then to be laid upon that mould, a foot asunder, with their cut ends somewhat sloping upward. When this first row of quick is thus laid, it must be covered with mould; some of the remaining turf must then be laid upon that mould with the grass side downward, as before; and more mould must afterwards be laid upon this turf. When the bank has, by these means, been raised about a foot high, a second row of sets should be laid in the spaces between the lower quick, and with their ends turned the opposite way, in order to thicken the bottom of the hedge. These are then to be covered in the same manner as the former: the bank is to be topped with the bottom of the ditch; and a dry or dead hedge must be made on the other side, to defend the young plantation from cattle.

"To make these dead hedges, stakes should be driven into the loose earth, so low as to reach the firm ground. They should be about two feet and a half asunder. Oak stakes are reckoned the best, and black thorn and fallow next. When they are fixed, small bushes should be laid at the bottom, but not too thick; for that would make the bushes rot. The upper part of the hedge should be laid with long bushes to bind the stakes in, by interweaving them: and, to render this hedge yet stronger, it may be eddered, as it is called, that is, the tops of the stakes may be bound in on each side, with slender long poles or sticks. When this eddering is finished, the stakes should be driven anew; because the doing of that, together with the weaving of the hedge, will probably have loosened them.

"The quick must be kept constantly weeded, and secured from being cropped by cattle, and in February it should be cut to within an inch of the ground; for this will make it shoot strong, and greatly help its growth.

"When a hedge of this kind is about eight or nine years old, it will be proper to plash it; the best time for which is in October or February.

"After it has stood twenty or thirty years, and there is in it old stubs, as well as new shoots, those stubs should be cut sloping off within two or three inches of the ground, except the best and longest of the middle size, which should be left to lay down, and some of the strongest, which should be cut off at the height of five or six feet, according to the intended height of the hedges. These last may be left to serve instead of stakes, and fresh stakes should be put wherever they are wanted. The hedge should be thinned, so as to leave on the stubs only such shoots as are designed to be of use, that there may be room left to put a spade in between them, in order to give the earth as good a stirring as possible. The ditch also should be cleaned, and its slopes carefully repaired; and where the earth has been washed from the roots of the quick, or is hollow, it should be faced anew with so much of the first spit of earth as there is occasion for: the second spit of this earth should be laid on the top of the bank; for if it be laid on the side or face of the bank, it will slip again into the ditch when wet comes, and perhaps drag down a great deal of the bank.

"Two extremes are to be avoided in the plashing of quicks: the first is, the laying the plashes down too low, and too thick; because that makes the sap run wholly into the shoots, and leaves the plashes without nourishment, which, with the thickness of the hedge, kills them. The second is, not to lay them too high; because this draws all the sap into the plashes, stunts the shoots at the bottom, and renders the hedge so thin, that it will neither hinder cattle from going through, nor from cropping of it.

"When the shoot designed to be plashed is bent, give it a small cut with a bill, half through, slanting a little downward; then weave it about the stakes, and trim off the small superfluous branches that straggle too far out on either side of the hedge.

"If the stubs are very old, cut them quite down: secure the chafms with a good dead hedge on each side, till the young shoots are got up tall enough to plash; and plant new sets in the vacant spaces.

"If the bank for a fence be without a ditch, and it is intended to make a hedge of quicks, the sets, prepared as before, should be planted in two rows, almost perpendicular, at the distance of a foot from each other, in the quincunx order; so that in effect there will be only six inches asunder." *Miller's Gard. Dict.*

Mr. Marshall, in his Minutes of Agriculture, in Norfolk, makes the following observation. "October 28th, 1782. This morning I observed some workmen fencing a rick-yard with furze-faggots alone: a species of fence I have not met with before.

"In a trench, about eighteen inches wide, and six inches deep, they set the faggots, as close as possible, upon their ends; spreading the bottoms, and covering the skirts with the loose mould dug out of the trench; also with that of a narrow trench, (a spade's width) dug for the purpose, on each side; treading the mould firm to the roots of the faggots; which being sufficiently loaded, the trench-lets were shovelled, and the banks smoothed.

"One of the labourers says, he has set a furze-fence in this manner across Gresham-field (an exposed situation): which has stood one or two winters.

"Furze-faggots, thus placed, are a fence against every kind of stock; even hogs and hares; and, in a country over-stocked with the latter, might frequently be used, as a temporary fence, with great advantage."

When the plants of the thorn are themselves stunted, or much decayed, as they generally are pretty soon, through the unmerciful wounds given them by unskilful hedgers; instead of plashing them, the farmer's best way will be to dig them up, and plant young sets in their stead. The only inconvenience attending this renewal, is the expence of a dead hedge, which is not wanted in plashing: but I question much, whether the healthiness of the plants, when cut smooth, and in such a manner as not to retain water, may not sufficiently compensate that charge. For the same reason, it seems to be most rational to cut the plashes upward; because the wound will then be covered from the wet, at least in some degree, by the slip which remains prominent over it.

Besides the plants already mentioned for hedges, the sweet-briar, or eglantine (dog-rose), is thus recommended by a correspondent of the Society of Improvers in the Knowledge of Agriculture in Scotland, who had tried in vain, in that country, all the methods of fencing usually practised in Hampshire and Essex.

"Observing that no creature eat up or destroyed the sweet-briar or eglantine (dog-rose) I gathered the hips of this plant, and laid them in a tub till March: the seeds then rubbed out easily, and I sowed them in ground prepared for garden-peas. By this means I got my crop of peas without prejudice to my briars, which came up the next year; and the year after, when they were about a foot high, I planted them in the following manner:

"After marking out my ditch, I laid my plants about eighteen inches asunder, upon the side-grass, and covered their roots with the first turfs that were taken off the surface of the intended ditch. The earth-side of these turfs was placed next to those roots, and upon the turfs was laid other earth, taken out of the ditch, which I then finished. In four or five years, these plants made a fence which no sheep, cattle, or horses could pass. If old briars are dug up, and divided, they make excellent plants. Where the fences are thin, they may be easily thickened, by laying down branches; for these will make shoots of six or seven feet in a year. They bear clipping very well.

"In sandy places, I seldom care to throw all the earth out of the ditch at once, but wait a year, till what I had thrown up is settled and swarded a little; then I raise my bank to the intended height. In the mean time nothing hurts my briars; and in two or three years after they have been planted, nothing can pass the fence. Sheep sometimes attempt it; but they soon are so entangled, that they would lie there till they die, if they were not taken out."

In the hedges which divide the farmer's fields only, fruit-trees may be planted; and these will yield profit, as well as ornament; or the fruit may be grafted upon a stock in the hedge, properly suited thereto.

These stocks should be pruned up every year, till they are brought out of the reach of cattle, and then they may be grafted with the red-streak, gennet-moile, or any other fruit. If they have proceeded from apple-kernels, they may remain ungrafted, and will yield very good cyder-fruit: but then it will be longer before they bear. Also, if the leaf, shoot, and bud of a natural stock, promise more than common, a trial may be made, whether that stock will not perhaps produce a fine new fruit; and if it be not liked afterwards, it may then be grafted.

Mr. Miller reckons, the plants raised from the kernels of the small wild crab is much better for hedges, than those which are raised from the kernels of any other sort of apple; because the former never shoot so strong as the latter, and therefore may be better kept within the proper bounds of a hedge; and as they generally have more thorns upon them, they are better guarded against cattle.

Mr. Young, in his Annals of Agriculture, vol. VI. observes, that "Mr. Bakewell is very curious in his fences, and plants his quicks in a different manner from what is common in various parts of the kingdom. He plants one row at a foot from set to set, and, making his ditch, lays the earth which comes out of it to form a bank on the side opposite to the quick. In the common method, the bank is made on the quick side above it. Reasons are not wanting to induce a preference of this method. The plants grow

only

only in the surface earth, uncovered from the atmosphere, which must necessarily be a great advantage; whereas, in the usual way of planting that earth, which is always the best, is loaded by a thick covering, obliquely, of the earth out of the ditch. If the roots shoot in the best soil, they will be out of the reach of the influences of the air, the consequence of which is, they cannot have so large a space of that earth, as if set on the flat. The way to have a tree, or a quick, thrive in the best manner possible, is to set it on the surface, without any ditch or trench; that cuts off half its pasture. But if a ditch is necessary, the next best way must of course be still to keep it on the flat surface; and the worst way, to cover up that surface, by loading it with the dead earth out of a trench. To say that there are good hedges in the common method is not a conclusive argument, unless both were tried in the same soil and exposure.

"In some cases, however, there is in this country, and Mr. Bakewell's farm is not free from it, a great waste of land, in making new fences. The ditch and bank are made as I have described, and then there are added a double post and rail, one on the outside of that bank, and the other on the outside of the quick, which altogether take up an enormous space of land."

Mr. Young, in his *Annals of Agriculture*, inserts the following new method of fencing, by W. Erskine esq.

"The importance of good fences is universally acknowledged by every lover of husbandry, although there are various opinions about the kinds of them, every one being naturally prejudiced in favour of those he has been most accustomed to see, or by the opinion of others whose judgment he relies on. An intelligent correspondent, in the second volume of the Bath papers on Agriculture, is so warm an advocate for quickset hedges, as to make him totally condemn the dead walls which are to be seen on the road between Bath and Cirencester, and in many other parts in England. I hope he will not take it amiss, if I cannot absolutely assent to his assertion, "that quickset hedges are more useful and profitable;" that they are more ornamental cannot be denied, and they are generally allowed to afford more shelter, but the length of time, the constant attention, and continual expence of defending them until they bear even a resemblance of a fence, induces many people in those places where the materials are easily procured, to prefer the dry stone walls; for though the first cost is considerable, yet as the farmer reaps the immediate benefit of the fence (which is undoubtedly the most secure one), they are thought on the whole to be the least expensive; besides, the cattle in exposed situations, and especially in these northern parts, are so impatient of confinement at the commencement of the long, cold, wet nights, that no hedges I have ever yet seen in any part of this island, are sufficient to keep them in. These inconveniences probably suggested to the late sir George Suttie (eminent in East Lothian, for his love and skill in agriculture) an idea of a fence, that at once joined the warmth and ornament of the hedge with the almost perpetual fence of the wall.

"If I mistake not, you have in some of your useful works, recommended hedges to be planted against the common dry stone walls: sir George Suttie has rather improved on this thought; he planted his hedges after the common method here, in the face of the ditch; but instead of putting a paling or post and rail on the top of the bank, he placed a wall of two feet and an half high; his local situation induced him to build with lime, and in places where that commodity is tolerably reasonable, it is the best method, as the satisfaction they afford by requiring no repairs, and the duration of them more than repays the expence; but where the price of lime is high, they may be built without any cement, and answer the purpose very well, if the work is properly executed.

"I have now experienced the benefit of these fences for some years, so that I can, with great confidence, venture to recommend them; indeed their superiority over all others is so manifest to every one who has seen them, that they are daily becoming more and more common in this country. As it would afford me great pleasure, if I could by any means extend the benefit of them to those gentlemen, whose situation are peculiarly adapted for them, I have endeavoured to render the making of them easy by the inclosed sketch and description; which if you think sufficiently plain and intelligible, I beg of you to favour this with a place in your valuable work, as that may perhaps induce some

gentleman or other in Gloucestershire, Oxfordshire, Yorkshire, &c. &c. to make trial of them; and if they are successful in getting them properly executed, I am fully persuaded that every one who sees them will acknowledge them to be the most agreeable and complete fence ever contrived.

"When a new fence is proposed to be made, the surface of the ground of the breadth of the ditch, and likewise for two feet more, should be pared off, in order to prevent as much as possible the weeds and grass from hurting the growth of the young thorns. See Plate VIII*, for a view of the fence.

"The ditch should be 5 feet broad, 2½ deep, and 1 foot broad at the bottom; leave 1 foot for an edging or scarcement, then dig the earth one spit of a spade for about one foot, and put about three inches of good earth below the thorn, which should be laid nearly horizontal, but the point rather inclining upwards, in order to let the rain drip to the roots, then add a foot of good earth above it; leave three or four inches of a scarcement before another thorn is planted; it must not be directly over the lower one, but about nine inches or a foot to one side of it; then throw a foot of good earth on the thorn, and trample it well down, and level the top of the bank for about three feet and a half in order for the base of the wall to rest on. The base of the wall should be about nine or ten inches (but must not exceed one foot) from the thorn. The wall to be about two feet thick at the bottom, and one foot at the top; the cope to be a single stone laid flat, then covered with two sods of turf, the grass of the undermost to be next the wall, and the other sod must have the grass side uppermost; the sods should be of some thickness in order to retain moisture, so that they may adhere together, and not be easily displaced by the wind; the height of the wall to be two feet and a half, exclusive of the sods, which together should be from four to six inches, by which means the wall would be near to three feet altogether.

"I would willingly add the cost of these fences; but as the rate of wages, and the quantity of work performed for them, differ so widely in one place from another, that I can only offer some data to enable people in different places to form some conjectures about them.

"I have them done, every thing included (the walls built with lime) from 10½d. to 13d. per ell (which ell is equal to 37 inches 2 parts) according to the ease and difficulty of working of the quarry, and the distance of it from the place where the fence is erected.—The lime costs about 6d. per boll (the boll is equal to 4 bushels, 0872,66 parts). I use from 15 to 16 bolls of lime to the rood of 36 square ells, Scotch measure; there are upwards of 43 Scotch ells, or 44 English yards, in length in a rood of a wall two feet and a half high.

"Sometimes where there are plenty of what is here called land stones, such as flints, &c. on the ground that is to be inclosed, I use them; it then requires from 30 to 35 bolls of lime to the rood.

"The thorns are to be brought from any nursery-man who commonly raises them from the seed, and sells them from 5s. to 10s. per thousand, according to their age, reckoning six score to the hundred.

"I generally have the ditches, as well as quarrying the stones, loading them, and building the wall done by the great, and commonly pay for making the ditch, laying the thorns, and preparing the top of the bank for the wall, from 7d. to 8d. for six ells running measure.

"The wages of day labourers here are from 8d. to 10d. per day, commonly 9d. The stones are quarried from 8s. to 12s. per rood, according to the softness or hardness of the quarry.

"The quarrier's wages are from 12d. to 16d. per day—I give the masons from 11s. to 12s. per rood, for building.

"The wages of such kind of masons, are from 14d. to 16d. per day.—About 50 carts (the weight that the cart carries from 7 to 9 cwt.) will build a rood. Carriage of ditto, about half a mile distance, about 8s. 4d. per rood, (2d. per cart). The hire of these carts are from 1s. 6d. to 2s. per day; the man generally drives two carts, sometimes a man and boy drive 5 carts.

"In the second volume of your six months Tour, you have given a letter from sir Digby Legard, wherein he acquaints you, that the dry stone walls of 4½ feet high, in the Wolds of Yorkshire, costs about 6s. for seven yards in length; and

and by your account, in the same volume, of Mr. Danby's, he gets his walls of six feet high for 5s. 6d.

"Sir George Suttie's fences are peculiarly adapted for these places, as the addition of the ditch and hedge cannot cost 3d. per running yard, and the height of the wall being so much lowered, encloses almost double the quantity of ground.

"Warmth is certainly as beneficial to hedges as trees, and the walls gives the shelter so absolutely necessary for rearing of young hedges, in very exposed situations, and they likewise preserve a proper moisture about the roots.

"If the hedges have been planted six or seven years before the wall is built, cut them over within two or three inches of the ground with a sharp tool, either in October or November, or early in the spring, and erect the wall as early in the season as possible, which in this country scarcely begins before the latter end of March. It is almost impossible for any one, who has not seen any of these kind of fences, to conceive the rapidity of the growth of the hedges in favourable situations. I had one cut over in the spring, and by the end of the year it was almost as high as the wall, and in three years time I am pretty positive no sheep would attempt it, not even the wildest Highland ones, who make nothing of a wall of 4½ feet high.

"When I first began to make these fences, I committed some error, having never seen any of them, which experience has taught me to correct. I drew the top of the wall to a point, and put too much earth on the bank, which made the wall stand too far from the hedge, and that allowed the cattle to get between the hedge and the wall, which, besides retarding the growth of the hedge, enabled them to get over the wall.

"In order to save the expence of the defending the hedge on the side of the ditch, the field should be thrown into that course of crops, as not to require to have any cattle in it for four years, by which time, in tolerable good ground, it will require none, as the hedge will nearly cover the wall, if kept clean for the two or three first years."

Fences made in marshy grounds require plants which delight in moist soils. Of this kind are, particularly, the black-alder, the willow, and the poplar: the birch-tree, and the ash will likewise grow very well in such places; but the first of these, viz. the alder, is reckoned the best and most profitable.

It likes a soil so moist as few other trees will thrive in, and is propagated either by layers, or planting of truncheons about three feet in length. The best time for planting these last is in February, or the beginning of March, when they should be sharpened at their larger end, and the ground should be well loosened before they are thrust into it, lest the bark should be torn off, which may occasion their miscarriage. They should be set at least two feet deep, to prevent their being blown out of the ground by violent winds, after they have made strong shoots, and they should be kept clear from all such weeds as grow tall, at least till they have got good heads; after this, they will keep down the weeds, and require no farther care.

If alders are raised by laying down the branches, this should be performed in October, and by the same time twelvemonth they will have roots sufficient to be transplanted, which must be done by digging a hole, and loosening the earth in the place where each plant is to stand. The young sets must be planted at least a foot and a half deep, and their top should be cut off to within about nine inches of the ground; for this will make them shoot out many branches.

The alder tree may be trained into very thick close hedges, to the height of twenty feet and upwards. It will thrive exceedingly on the sides of brooks, for it grows best when part of its roots are in the water, and may, if planted there, as is usual for willows, to be cut for poles every fifth or sixth year. Its wood makes excellent pipes and staves; for it will last a long time under ground, or in water; and it is likewise much esteemed by turners, plough-wrights, &c. and for making several utensils necessary in agriculture. Its bark yields a good black dye.

All the sorts of willows, of which Mr. Miller enumerates fourteen, grow best in moist boggy land, and may be easily propagated by planting cuttings or sets, either in the spring or autumn: for these readily take root, and are of quick growth.

In countries where there is great plenty of rough flat stones, the fences which bound an estate, or farm, are frequently made with them. It is a pretty common practice in Devonshire and Cornwall, where they build as it were two walls with these stones laid one upon another, first two, and then one between; and as the walls rise, they fill the intermediate space with earth, beat the stones in flat to the sides, which makes them lie very firm, and so proceed till the whole is brought to the intended height. They then plant upon these walls quick hedges, and even timber trees, which thrive exceedingly; and they esteem these fences the best security that can be to their ground and cattle. However, if these stones are laid rough and dry, they cannot but be disagreeable to the eye, and must certainly require frequent repairs, because they will often be forced out of their places, or beaten down by cattle.

To prevent this, let such walls be built in the bottom of a ditch, made wide enough for the purpose, and sloped down on each side. The deformity will then be hid; and as the cattle cannot stand facing the wall, so as to attempt to leap over it, the stones of which it is composed will be the less liable to be beaten down. The earth taken out of the ditch may be spread on the adjacent ground, and its sides may be planted with such trees, or under-wood, as best suit the soil. If a space of several feet proportioned to the demand which there may be for timber, is left on the inside of the fence, it will be attended with every advantage arising from a supply of that necessary commodity; without prejudice to the arable or more valuable pasture.

Another very strong and durable fence may be formed thus, in grassy places. Dig pieces of turf, four or five inches thick, the breadth of your spade, and about a foot long. Lay these turfs even, by a line on one side, with the grass outward, at the distance of ten or twelve inches within the mark, at which the ditch, afterwards to be dug in the solid ground, is to begin. Then lay in the same manner, but with their grass-sides turned out the contrary way, another row of turfs, at such distance as to make a breadth of foundation proportioned to the intended height of the bank. The reason for placing these turfs thus much within what is to be the edge of the solid ground dug away on each side, is to prevent the bank from falling in, if the ground underneath it should be any way defective. A ditch, of what breadth or depth you please, may then be dug; or the ground may be lowered on each side with a slope; in which last case there will be no loss of pasture by the fence, because it may be sowed with hay-seeds, and will bear grass on both sides. Part of the earth taken out of the ditches or slopes, will fill the chasm between the rows of the turf, and the rest may be scattered over the adjacent ground. Three, four, or more layers of turf may be thus placed upon one another, and the interval between them filled up as before, till the bank is brought to the desired height; only observing to give each side of it a small slope, for greater strength. The top of this bank should be about two feet and a half wide, and the whole of it should be filled up with earth to a level with the turfs, excepting a little hollow in the middle, to retain some rain. Quicksets should then be planted along this top, and they will soon form an admirable hedge. By this means, a bank four feet high, and a slope only two feet deep, will make, besides the hedge, a fence six feet high, through which no cattle will be able to force their way: for the roots of the grass will bind the turfs so together, that in one year's time it will become entirely solid; not a joining will appear, nor a turf can be got out; and it will be yet much stronger, when the roots of the quick shall have shot out among it. The only precautions necessary to be observed here, are, first, not to make this bank when the ground is too dry; because, if a great deal of wet should suddenly follow, it will swell the earth so much, as, perhaps, to endanger the falling of some of the outside, which, however, is easily remedied if it should happen; and, secondly, if the slope be such as sheep can climb up, to secure the young quick at the time of planting them, by a small dead hedge, either on or near the top on both sides. If any of the quicks should die, which they will hardly be more apt to do here than elsewhere, unless, perhaps, in extreme dry seasons, they may be renewed, as in other places, by planting new ones, or by layers from those which remain.

A fence like this will even do for a park; especially if posts and rails, about two feet high, are placed a little

sloping

sloping over the side of the bank, on or near its top: for no deer will be able to jump over this, nor can they creep through it.

This is one of the best fences to afford shelter for cattle; and if the quick on the bank is kept well clipped, it will form a kind of green wall, pleasing to the eye.

When the bounding fence is only to guard against accidents from without, it may be made in the ha-ha manner; only taking care that the earth be so well rammed down at the back of the wall, as that the stones may be properly supported, and bear equally.

The ingenious author of the *Essays on Husbandry* recommends the horn-beam plant, as one of the best yet known for making fences, according to the method used in Germany, where such fences are common.

"When the German husbandman, says he, erects a fence of this nature, he throws up a parapet of earth, with a ditch on each side, and plants his horn-beam sets in such a manner, as that every two plants may be brought to intersect each other, in the form of St. Andrew's cross. In that part where the two plants cross each other, he gently scrapes off the bark, and binds them with straw thwart-wise. Here the two plants consolidate in a kind of indissoluble knot, and push from thence horizontal slanting shoots, which form a sort of living palisado, or *chevaux de frise*; so that such a projection may be called a rural fortification. The hedges being pruned annually, and with discretion, will, in a few years, render the fence impenetrable in every part." *Essays on Husbandry, Essay I. page 14.*

High fences are nuisances on arable land, for when heavy rains fall, the corn of narrow close fields, and every where under high trees, is liable to be lodged; but in large open fields, or where the hedges are low, very little damage will be done. The fences of an arable field ought not to be above four feet high; as a good ditch with a trimmed quick-hedge, Mr. Marshall says, is to be preferred before any other. He also says, dead hedges are a heavy tax on an inclosed farm; and live fences, except quicks, are barbarously treated in this country. Even quicks are generally hacked down to the ground, and a dead hedge raised behind the stumps, till the young shoots get strong enough for a fence. There are few old hedges without a sufficiency of live stuff in them, if it were properly treated, to make a fence. But instead of plashing and trimming this into the form of a hedge, it is all levelled with the ground; and, that the young shoots may not rise up in judgment on the folly, they are ingeniously smothered by a rough dead hedge placed immediately on the stubs. Should a hardy few escape total suffocation, they have no other way of enjoying the sun and air, than by shooting out horizontally across the ditch, or into the field; filling both the one and the other with weeds and other trumpery. He says also, if the hedge wants making, and there be live stuff enough for a fence, he recommends it to be plashed in the Yorkshire manner; if the live stuff be too thin, fill in with dead boughs. Such as do not require to be re-made, are to be treated as follows: with a sharp pea-hook or a common reaping-hook, (not a sickle) begin on the ditch-side, and strike off every thing, whether oak, hazel, black-thorn, or quick, stem or spray, dead or alive, which overhang the ditch; clearing at the same time the bank and ditch from grass and weeds. If the bank-side is free from trees, bushes, or other incumbrances, he recommends it to be treated in the same manner; leaving the hedge, whether crooked or straight, about a foot, and or a foot and half thick, clearing away the grass, weeds, and briars, as on the other side. The immediate neatness which this gives, is pleasing, and its utility obvious: there will be no waste ground, no harbour for weed; and where live shrubs abound, the fresh shoots the following spring will make it difficult for even a bird to get through them. If the bank-side is encumbered, he recommends to grub and plough close to the hedge, or plough close to the incumbrances, and trim back every thing which overhangs the last furrow. This alone gives a garden-like appearance, and will be worth all the trouble: but even this is not without its use: the nursery of weeds in a great measure will be destroyed, and a convenient path formed round the field. The farmer who will thus accommodate the sportsman in hunting, will always be favoured; for it is frequently with great reluctance that he will ride over wheat, because he could not keep the outside furrow, with-

out the hazard of being torn off his horse by briars and thorns, or having some violent blows from the boughs of the trees. Indeed the most pleasing reflection is, that all this utility, conveniency and lightness, may be obtained at a trifling expence. Mr. Marshall proceeds and gives the following account: viz. "I set a lad to trim the ditch-side of a rough black-thorn hedge, which had not been touched for twice seven years. The ditch was totally blinded with thorns, briars, grass, and weeds. The length was about 60 rods. He began about eight in the morning and finished about five in the afternoon. His wages did not amount to more than 15d. or a farthing a rod. The following day he trimmed back the overhangings of the outside furrow of a field of wheat of four acres, in four or five hours; by which any person could walk or ride round with pleasure, and view the coming crop without injuring it, which without this trifling labour and expence, could not be done with ease or conveniency."

Mr. Marshall, in his *Rural Economy of the Midland counties*; speaking of fences, says "At present, however, garden quick may be said to be the universal hedge-wood; although there was, within the memory of many men, no such thing in use."

"The rejection of nursery plants, however, did not proceed from ignorance in the method of raising them, but from principle, founded on a false notion, that plants, pampered in the rich soil of a garden, were of course improper to be planted in a ditch bank of common earth. No, no: the planters of those days knew better. "Gather them in woods, where they have been exposed to hardships, and have learnt to live upon coarse fare, and in that case, when they come to be transplanted into hedges, they must thrive."

"A gentleman near Tamworth was the first who ventured to plant garden quick on a large scale; and his success ruined the business, as it had long been, of quick-gathering. The quantity now raised, at Tamworth and its neighbourhood, for the Birmingham and other markets, is extraordinary. It is mostly transplanted. Its price, even at Tamworth, seven shillings a thousand: at Birmingham, eight to ten shillings: yet at those prices one gardener sells, even when no public inclosures are going forward, three or four hundred thousand annually."

"The most judicious planter I met with in the districts, and from whom, with the gardener here alluded to, I had these particulars, chuses his plants at four years old, transplanted at two; and cares not how rich a soil they are raised in."

"The time of planting, here, is not unfrequently autumn. I had an opportunity of making a comparative observation, on a neighbour's practice, between plants set in autumn, and others planted, in continuation of the same hedge, in spring. The autumnal planting, in this case, had a decided preference. But the situation was somewhat dry, and the spring and summer proved so likewise:—under these circumstances autumnal planting will generally succeed best."

"The method of planting has been said to be that of putting the plants into a broad flat mound: generally planting two rows, ten or twelve inches apart, and a similar distance from the brink of the trench, by the side of which they are planted."

"The reason given for this mode of planting is, that a deep ditch makes a high heavy bank, and this overloads the roots."

"There is, no doubt, some truth in this reasoning. Plants never thrive so well as on level ground, provided they are not incommoded by standing water: but it is a fact, evident in various parts of the kingdom, and particularly in my own practice, in three different and distant parts of it, that hedges may be raised with success in the front of a high bank; and that its disadvantages are by no means equal to the advantage gained by a deep ditch and high bank, as a defence to the rising hedge."

"Two rows of posts and rails are here the common guard: incurring an expence equal to twice that of a deep ditch and banklet on one side, and a high bank and hedge on the other. If the hedge be planted behind a shelf of sufficient width, and part of the mould of the ditch be applied in forming a banklet on its outer brink, the load incurred by the remainder is little, if any impediment, to the progress of the young hedge."

"The method of planting a hedge in this manner is mentioned above."

"The nursing of young hedges, a business which, in most

most parts of the kingdom, is in a manner totally neglected, is in many cases well attended to here. They are pretty generally weeded, and, in some instances, hoed: in others, however, they are here, as in other places, seen struggling among weeds; principally of the following species.

"I enumerate them here, as I paid more attention to hedge-weeds in this, than in any other, district: and though they vary in some degree, in different places, they are, upon the whole, very much the same in all.

"The treatment of grown hedges. Plashing may be called the universal practice of this district. Nevertheless, I have observed a few instances of cutting hedges, that do not come within the description of plashing.

"In this practice, one row of stems, if double quicked, is cut to the stub, the other, hedge height; not level off, or all of the same height, but in such a manner as to lean back, away from the stubs of the fallen row; cutting those which stand foremost the lowest, and such as lean or branch away from them, the highest; leaving the back spray on, to form a blind, and assist to make a fence.

"Under this management, two rows of quick are evidently preferable to a single row; for although I have seen single quick treated somewhat in this manner, especially in Derbyshire, the effect is very different. In this case the stools and the stems are fed from the same roots; the same set of fibres; and the stems with the spray left upon them, rob the lower shoots, from which the new fence is to rise, of a great part of their sap; while in the other, the stools not only stand distinct from the stems, but have a distinct set of roots to support them, entirely independent of the stems left standing as a temporary fence.

"The methods of plashing are various: the old and still most prevailing method is to leave part of the stems standing, as live stakes; between which the plashers are interwoven, in the usual manner.

"Judicious managers, however, object, and with good reason, to live stakes; which, throwing out spreading heads, in the pollard manner, overhang and destroy the plashers, and prevent the shoots of the stools from rising: consequently tending to convert the hedge into a row of thorn pollard; in which state old hedges, that have been thus treated, are too evidently seen. On the contrary, when the entire hedge is cut down, or crippled as plashers to the stub, the plashers have no impediment, and the young shoots are the less incommoded, in as much as the plashers shoot less luxuriantly than the stakes. Still, however the shoots from the stools, the only offspring of the old hedge from which a new one can be expected, are greatly injured by the plashers overspreading them.

"Hence an improvement has been struck out, in this district, which probably raises the art of plashing to its highest degree of perfection. This is effected by driving the dead stakes, not in a line with the stubs, but some foot or more behind them, and by winding the plashers among them, and eddering them, according to the custom of this country, with brambles, leave the shoots from the stubs the same air and head-room, or nearly the same, as if the whole were cut down, and a dead hedge raised behind them.

"The advantage of this method of plashing, compared with the practice of felling the whole to the stub, is, that a live hedge, which improves by age, is raised, instead of a dead one, which grows worse every year. The disadvantage, that of part of the sap (of single hedges) being drawn away from the young shoots; which, in this case, are left less free and open than when the whole of the stems are cleared away at the stub.

"However, where there are a sufficiency of young pliable stems for plashers, and the ditch does not require much repair, the plashing here described may have, upon the whole, the preference; especially if the plashers, when the young hedge has got up, be removed from their interference with upright shoots.

"But, where the hedge has been neglected, the stems are grown few and large, particularly where vacancies require to be filled up by layers or otherwise, and the ditch requires to be new made, felling to the stub is indisputably preferable.

"It is observable, however, that in the district under survey, the ditch is rarely remade, and but seldom scoured: even where the soil is retentive; and a ditch, of course, necessary to good management.

"The reasoning, in this case, is the same as in that of planting by a narrow ditch: namely, the fear of overloading the roots. In that case there may be some shadow of truth; but in this, in which the roots are feeding several feet from the bank, there is probably not the least foundation. The practice, no doubt, originates in indolence or false economy.

"This censure, however, is not intended to be passed indiscriminately. There are many individuals, who are aware of the utility of open ditches, in freeing their lands from surface water."

FENNEL, the name of a well known plant cultivated in kitchen gardens. It is propagated by the seeds, which ripen in autumn, and should be sown soon after. They will come up in the spring, and require no other care than to keep them clean from weeds. This plant will grow in any soil or situation.

FENNY, moorish, marshy, boggy.

FENNY-LAND. See the article BOG MARSH, and MOOR.

FERMENT, the substance used to raise a fermentation, as yeast, wine-lees, leven, &c.

FERMENTATION, an intestine motion excited in vegetable substances, whereby the cohesion of their parts are destroyed, and may easily be separated from one another.

In every fermenting liquor, an intestine motion is generated in all its parts. It is called intestine, because it is excited by the internal principles contained in the vegetable juices; for vegetable juices or infusions made in water, however bright at first, and apparently homogeneous, on being kept in a moderately warm place, in vessels not closely stopped, become turbid, conceive an intestine motion, emit numerous air-bubbles, and discharge a pungent vapour of extreme subtilty.

All bodies which may be so changed by this intestine motion, as to produce wine, are said to be fermentable: and as this was never found to happen in any other than vegetable substances, vegetables alone are said to be fermentable.

The fermentable class of vegetables are extremely various, and might be distributed into as many classes, as they require different methods of fermenting. We shall, however, mention them no further than they relate to the pleasure and profit of the husbandman.

The first class of fermentable substances, includes all the pulpy summer fruits, which, when ripe, abound with a tartish sweet juice: such as grapes, apples, pears, elder-berries, gooseberries, raspberries, currants, cherries, plums, and all other summer fruits, provided they be kept free from a tendency to putrefaction.

The second class contains the fresh expressed and native juice of plants, provided they be of a tartish and sweetish taste; such as the juice of the sugar-cane, of liquorice, and other similar plants. To this class may be added all the juices which distil from certain trees when wounded, especially in the spring; as the birch, the plane or maple, the vine, the walnut-tree, &c. The maple has this remarkable property, both in the small kind and in the great, which is called the sycamore, that, being tapped, it will bleed freely in the winter, and its juice will flow very plentifully even after a hard frost. All these juices generally run into a spontaneous fermentation.

The third class comprises those vegetable juices which are formed and insipidated by nature into a certain saponaceous substance, consisting of saline and oily particles; such as honey, manna, and all other juices which are not gummy or unctuous.

The fourth class comprehends all those seeds which, when ripe and dry, may be ground into a fine meal, without their forming an unctuous paste; such are barley, wheat, oats, rye, &c.

Certain physical circumstances are requisite to render these different substances fit for fermentation; namely, first, a perfect degree of maturity suitable to each kind. All seeds and fruits which are so perfect, as, when sown in fertile ground at a proper season, and in a proper climate, to produce a plant of their own species, are fit for this operation. Another requisite to fermentation is a moderate proportion of oil: for though fat subjects are more apt to grow rancid, than to ferment, yet if they are entirely deprived of their oils, they are hereby also rendered unfit for fermentation. Thus, bruised almonds, which are rich in

oil, will scarcely ferment; but they may be so far freed from their oil by art, as to be made fitter for this purpose. Solubility in water is a third and principal requisite in fermentable subjects.

The methods of preparing each fermentable substance for fermentation will be given under the articles WINE, CYDER, and BEER.

The juices of summer fruits are, of their own nature, greatly disposed to ferment, so as immediately to begin this operation, without the addition of any other ferment. Other liquors may, however, stand in need of the help of other ferments, to begin this intestine motion, which, under proper conduct, proceeds afterwards of itself. The chief of these ferments is the recent flowers, commonly called yeast, thrown up to the top of beer in the act of fermentation: for if this rarefied frothy matter be mixed with other fermentable liquors, it greatly promotes their fermentation. The same matter become heavier, and sunk to the bottom, provided it be not too stale, still retains the same vigour, though in a less degree, than its former state. The remains of former fermenting liquors sticking to the sides of casks, have the same effect: for casks thoroughly penetrated by the subtilty of wines which they formerly contained, are extremely apt to raise a violent and quick fermentation in the fresh liquors put into them. Acid paste of flour fermented, or baker's leaven, may all be employed for the same purpose: for though meal may be preserved fresh and sweet during years, if it be kept in a dry state, and perfectly free from insects; yet if it be wrought with water into a soft close paste, and lightly covered in a warm place, it will soon begin to heave, be all over full of cavities, change its smell, colour, and tenacity, prove acid both to taste and smell; and thus become that proper ferment from which the whole of this operation first took its name. When thus prepared, if part of it be mixed with other paste, fresh and not yet fermented, it will cause this to ferment much sooner, and more strongly, than it would otherwise do. Hence, we need not be solicitous about a first ferment, because nature affords it spontaneously every where. The great promoters of all the stages of this process are warmth, a moderate admission of air, and the addition of actually fermenting matter.

If we take large glass bodies, place them upright where they may be kept in an equal heat, and then fill each of them three quarters full with a crude fermentable liquor well prepared for the operation, the orifice being slightly covered with a cloth, and a heat kept up to above sixty degrees; it will be pleasing to observe the several degrees of fermentation.

The mass, at first resting, and possessing a certain space in the vessel, gradually begins to swell, rarefy, and conceive an intestine motion through its whole body, acting upwards, downwards, and side-ways, in strange circumvolutions without ceasing, though with a different force. In the mean time bubbles are every moment formed in every part of the mass, and constantly endeavour to rise up to the surface, where they burst with a hissing noise, or often break in the mid-way. Hence the whole mass froths, discharging with an audible ebullition a certain tartish spirit, which proves acrimonious to the nose, surprisingly elastic, and capable of bursting almost any vessel by its great expansive force. If a large vessel full of fermenting must, in the height of its action, should discharge this condensed spirit through a small orifice, and a strong healthy man should draw in at his nostrils the vapour so issuing, he would instantly fall down dead; or if he received but little thereof, he would become apoplectic, and remain an idiot his whole life. When this vapour is confined and accumulated in close rooms, it will extinguish fire, and suffocate animals. Its producing the first of these effects is a sign that it is collected in sufficient quantity to cause the other. While candles continue to burn, we need not be afraid that this wild gas, as Helmont calls it, will be dangerous to life. It is on account of this spirit, that people are obliged to air wine-vaults, where wines are fermenting in the vintage season, by setting open the windows, lighting fires, and letting in the wind.

In the progress of fermentation, the grosser parts of the mass begin to rise to the top, and separate there from the other liquor below, so as to collect into a spongy crust, which exactly covers the liquor underneath, and keeps in the more active parts thereof, in such manner as to prevent their being exhaled and dissipated before they have performed their effect. Now, it is curious to observe how

great the agitation constantly is every where, even in the smallest part of the fluid matter, below this crust. A greater attrition can scarcely be conceived, than that which is here made with the utmost rapidity among all the particles. The crust being successively broke, and raised up with a considerable noise, upon the returns of the explosions, the exhalations escape, while the crust, presently falling together, closes again, and prevents the active principles from exhaling otherwise. Thus, the formation and continuance of the crust is greatly assisting in the due performance of fermentation.

As soon as all the gross parts of the mixture are thus collected at the top, some less rarefied particles of the lower part of the crust, being no longer sustained by the light bubbles which caused them to ascend, begin to sink through the fluid, and are agitated upwards and downwards by bubbles in and about themselves, by means of which they are again raised to the top, from whence, upon the breaking of the bubbles there, they again fall downward; and when they have done this several times, they at length remain quiet at the bottom. After this, new little masses do the same; and after some continuance thereof, it frequently happens that all the upper crust, then grown heavier, or less rarefied, on account of the air discharged, sinks of a sudden downward, but soon after rolls upward, almost entire, with such a force as would seem incredible, if it were not seen. When the upper crust is thus gradually consumed and fallen to the bottom, the fermentation ceases, though the same degree of heat be continued; and the liquor, then floating over the faeces which remain at the bottom, becomes transparent.

So long as the crust remains at top, it is called the flowers of the fermenting liquor, and is the most proper and immediate ferment. What falls to the bottom is called lees.

The time requisite for the perfect completing of fermentation can hardly be determined, because it is different in different liquors, and depends much on the season of the year, and heat of the weather. The juice of the palm-tree finishes its fermentation in a few hours in Africa; and this operation is likewise very soon ended in Asia; but in the northern countries, it proceeds slower. In the heat of summer it proceeds quick, but in winter more languidly. It is, however, easy to know when the fermentation is finished, viz. when the whole series of the phenomena above described, has successively appeared, and is at length spontaneously gone off. Then the vessel should be immediately stopped down, and the liquor should be kept for some time on its lees, a great part of which will be assumed and assimilated by the liquor, which will thereby become stronger and richer in spirit than it was before. If the vessel is not stopped down, the spirit produced in the fermented liquor will soon exhale, and leave behind only a vapid useless fluid; but if the liquor is kept quiet in a close vessel, it will gradually become more pure and spirituous. The sweeter and richer the juice is, the longer does the fermentation continue, and the stronger and more spirituous is the wine or other liquor.

The distinguishing marks of a vinous liquor are as follow: it has the faculty of inebriating, or altering the actions of the spirits and animal functions, by refreshing, animating, and exhilarating the drinker: after this, it raises the latent passions (*in vino veritas*), and finally, it destroys the external and internal senses and voluntary motions, and thus brings on a palsy, sleep, or at last death.

Fermentation also changes the relaxing, saponaceous, cooling, and generally purging virtues of vegetable juices, into such as are strengthening, coagulating, and healing. Thus, the fresh infusion of malt, before fermentation; solution of sugar or honey in water; the fresh expressed juices of ripe summer-fruits, &c. when plentifully drank, prove flatulent, purgative, weakening, and cooling; but when properly fermented into beer, mead, or wine, they have quite contrary qualities, which they had not before. It is a very singular property of fermentation, that it produces from fermented liquor a spirit which is convertible into a liquid flame, and yet may be perfectly mixed with water.

The things which promote fermentation, or tend to the better performance thereof, are free admission and emission of air, a warmth between fifty and seventy degrees, and the addition of a proper ferment.

It is found that when the sweet juices are boiled down to a thick consistence, they not only do not ferment in that state,

state, but are not easily brought to ferment, when diluted with as much water as they had lost in the evaporation. Juices and decoctions in general, which have suffered much fire, however sweet, are little disposed to ferment.

One of the chief checks given to fermentation, is the fumes of burning sulphur, received in a large quantity at several times, and shut up along with the air remaining on the top of the fermenting liquor. If the whole cask be penetrated and filled with the fumes of burning sulphur before the fermenting liquor is put in, and if the empty part on the top of the liquor be afterwards well filled with the same, and the vessel cautiously bunged down, the fermentation will certainly be stopped: and if, after some time, it should begin again, from the prevalency of its own cause, it may again be suppressed by the same fumes. The same end is also obtained by mixing with the fermenting matter a large quantity of any powerful acid, such as acid spirits of vitriol, or nitre; though these at the same time prove hurtful to the fermenting liquor. Alkaline salts likewise, if added in a large quantity to fermenting liquors, immediately excite an increase of effervescence, which presently ceasing, all farther fermentation is stopped. But here too fermenting liquor is spoiled, so that it can scarcely be brought again to ferment, though it may to putrefy. In the same manner, those things which destroy acidity by drinking it up, hinder fermentation. Thus, chalk, testaceous and calcareous substances, iron, lead, tin, have this effect. Stopping up, the containing vessels so close, that nothing can escape or enter, will stop the fermentation, provided the vessel be so strong as not to be burst by the force of the confined liquor. This is manifest in new malt liquors, which, when included in strong bottles, well corked, effervesce violently upon receiving the air. The extracting of the elastic air stops fermentation: too great heat rather dissipates and throws off the active principles of fermentation, than excites and promotes them; and lastly, too great a degree of cold likewise stops fermentation.

FERN, the name of one of the worst of weeds, and one of the most difficult to destroy where it has a deep soil to root in. Mr. Mortimer says, he has seen its root eight or ten feet deep in some grounds; and adds, that the best way of killing it is by cutting it often while it is in grass; that the most proper seasons for this purpose are the Spring, Midsummer, and Michaelmas: that is, when the circulation of the sap is strongest. Most of the roots being then cut asunder, and thereby deprived of the channels through which nature intended to convey the sap, will bleed to death, or, if it stagnates in them, they will soon rot. The fern itself, if cut when full of sap, and left to rot upon the ground, will greatly improve the soil, and mellow it so as to prevent its binding: or, if it be burnt when so cut, it will yield a much greater quantity of salt, than any other vegetable. If it be ploughed up, plentiful dunging of the land, and sprinkling it well with ashes, have been found to kill this weed: but the most certain cure for it is urine. In several parts of the North, where they keep their fern under, and destroy a great deal of it by mowing it frequently when green, they also find that rolling of it is of great service; and when they burn it, the poor people make the ashes of it up into balls, with a little water, dry them in the sun, and use them in washing their linen, for which they think them nearly as good as soap. Often treading down these plants, and feeding Scotch sheep on them, is said to be almost an infallible way of killing the fern.

When intended to convert to dung for manure, it requires a long time to mature, which is very much against it, as it will delay the maturity of a dunghill a full year longer than straw. Perhaps straw, at 15s. per load, is cheaper, and a more eligible litter, than fern at 5s. The received opinion that fern breeds smut, may be accounted for, by being mixed with straw; the latter of which will be fully digested, and fit for the field, when the fern is in the height of fermentation, swarming with animalcules of various species, in various states. These are of course conveyed to the soil; perhaps comes smut. From the straw-mixen will come a healthy, whilst from the fern, a diseased one. Indeed the fern retards considerably the maturation of the manure: but at the same time, Mr. Marshall says, he does not wish to decry fern wholly, as it may be very eligible in many situations; nor does he mean to convey an idea, that the manure produced from it is of an inferior quality to that produced from straw, if left long enough to mature: for he is of opinion, that ma-

nure from fern, thoroughly concocted, is as meliorating, and as free from infection, as that made of straw; and, where it can be kept separate, fern may be very eligible cart-horse litter.

Trees planted among fern will thrive very much, though it be on a hot gravel: the fern shading their roots, and keeping them moist and cool.

FERTILE, fruitful, abundant, plenteous.

FERTILITY, fecundity, abundance, fruitfulness.

FESCUE, the name of a genus of grass, of which there are several species; as the fote-fescue, the sheep's fescue, &c. See the article FOTE-FESCUE, SHEEP'S FESCUE, &c.

FESTING-PENNY, earnest given to servants when hired.

FETLOCK, the tuft of hair that grows behind the pattern-joint of many horses; those of low size have scarce any such tuft.

FETTERS, chains for the feet.

FEVER, a disease that frequently attacks several sorts of cattle, particularly horses.

The symptoms which denote the horse to be afflicted with a fever, are great restlessness, the creature ranging from one end of the rack to the other; his flanks beat; his eyes are red and inflamed; his tongue parched and dry; his breath hot, and of a strong smell; he loses his appetite, and nibbles his hay, but without chewing it, and is frequently smelling to the ground; the whole body is hotter than ordinary (though not parched, as in some inflammatory disorders); he dungs often, little at a time, usually hard, and in small bits; he sometimes stales with difficulty, and his urine is high coloured; he seems to thirst, but drinks little at a time and often; his pulse beats full and hard, to fifty strokes and upwards in a minute.

The first intention of cure is bleeding, to the quantity of two or three quarts, if the horse is strong and in good condition; then give him a pint of the following drink four times a day; or an ounce of nitre mixed up into a ball with honey, may be given thrice a day, instead of the drink, and washed down with three or four horns of any small liquor.

Take of baum, sage, and chamomile flowers, each a handful; liquorice-root sliced, half an ounce; sal prunel, or nitre, three ounces; infuse the whole in two quarts of boiling water, and when cold strain it off; then squeeze into it the juice of two or three lemons, sweeten it with honey.

As the chief ingredient to be depended upon in the drink is the nitre, it may, perhaps, be as well given in water alone; but as a horse's stomach is soon palled, and he requires palatable medicines, the other ingredients may in that respect have their use. Soleysel for this purpose advises two ounces of salt of tartar, and one of sal armoniac to be dissolved in two quarts of water, and mixed with a pail of common water, adding a handful of bran or barley-flower to qualify the unpleasant taste: this may be given every day, and is an useful medicine.

The following also may be given for this purpose:

Take Russia pearl ashes one ounce, distilled vinegar one pint, spring-water two pints, honey four ounces; give a pint three or four times a day.

This neutral mixture, and the nitre-drink above, may be taken alternately; they are both efficacious remedies, and in some cases may properly enough be joined with the camphor drink.

His diet should be scalded bran, given in small quantities; which, if he refuses, let him have dry bran sprinkled with water: put a handful of picked hay into the rack, which a horse will often eat, when he will touch nothing else: his water need not be much warmed, but should be given often, and in small quantities: his cloathing should be moderate, too much heat and weight on a horse being improper in a fever; which scarce ever goes off in critical sweats (as those in the human body terminate), but by strong perspiration.

If, in a day or two he begins to eat his bran, and pick a little hay, this method with good nursing will answer; but if he refuses to feed, more blood should be taken away, and the drinks continued: to which may be added two or three drams

drams of saffron, avoiding at this time all hotter medicines: the following clyster should be given, which may be repeated every day, especially if his dung is knotty and dry.

Take two handfuls of marshmallows, and one of chamomile flowers; fennel-seed an ounce; boil in three quarts of water to two, strain off, and add four ounces of treacle, and a pint of linseed oil, or any common oil.

Two quarts of water-gruel, fat-broth, or pot-liquor, with the treacle and oil, will answer this purpose; to which may be added a handful of salt. These sort of clysters are properer than those with purging ingredients.

The following opening drink is very effectual in these fevers, and may be given, every other day, when the clysters should be omitted; but the nitre-balls or drink may be continued, except on the days these are taken.

Take of cream of tartar and Glauber's-salts, each four ounces; dissolve in barley-water, or any other liquor: an ounce or two of lenitive electuary may be added, or a dram or two of powder of jallap, to quicken the operation in some horses.

Four ounces of Glauber's-salts or cream of tartar, with the same quantity of lenitive electuary, may be given for the same purpose, if the former should not open the body sufficiently.

In four or five days the horse generally begins to pick his hay, and has a seeming relish to food: though his flanks will heave pretty much for a fortnight; yet the temper of his body, and return of appetite, shew that nothing more is requisite to complete his recovery than walking him abroad in the air, and allowing plenty of clean litter to rest him in the stable.

This method of treating a fever is simple, according to the laws of nature; and is confirmed by long experience to be far preferable to the hot method.

The intention here is to lessen the quantity of blood, promote the secretions of urine and perspiration, and cool and dilute the fluids in general.

How far vinous cordials, strong beer drinks loaded with fiery powders, and such methods, are likely to answer these purposes, is submitted to the judicious observer; as also whether adopting the cool one in its stead is not as real an improvement in farriery as physic.

There is another sort of fever that horses are subject to, of a more complicated and irregular nature than the former, which, if not properly treated, often proves fatal.

The signs are a slow fever with languishing, and great depressions: the horse is sometimes inwardly hot, and outwardly cold; at other times hot all over, but not to any extreme; his eyes look moist and languid; he has a continual moisture in his mouth, which is the reason he seldom cares to drink, and when he does, it is but a little at a time. He feeds but little, and leaves off as soon as he has eat a mouthful or two; he moves his jaws in a feeble loose manner, with an unpleasant grating of his teeth; his body is commonly open; his dung soft and moist, but seldom greasy; his staling is often irregular, sometimes little, at other times profuse, seldom high-coloured, but rather pale, with little or no sediment.

When a horse's appetite declines daily, till he refuses all meat, it is a bad sign. When the fever doth not diminish, or keep at a stand, but increases, the case is then dangerous. But when it sensibly abates, and his mouth grows drier, the grating of his teeth ceases, his appetite mends, and he takes to lay down (which perhaps he has not done for a fortnight), these are promising signs. A horse in these fevers always runs at the nose, but not the kindly white discharge, as in the breaking of a cold, but of a reddish or greenish dusky colour, and of a consistence like glue, and sticks like turpentine to the hair on the inside of his nostrils. If this turns to a gleet of clear thin water, the horse's hide keeps open, and he mends in his appetite; these are certain signs of recovery.

The various and irregular symptoms that attend this slow fever, require great skill to direct the cure, and more knowledge of the symptoms of horse's diseases than the generality of gentlemen are acquainted with. The experienced farrier should therefore be consulted and attended to in regard to the symptoms; but very seldom as to the application of the remedy, which is generally above their

comprehension; though it may be readily selected, by duly attending to the observations here inculcated.

First then, a moderate quantity of blood, not exceeding three pints, may be taken away, and repeated in proportion to his strength, fullness, inward soreness, cough, or any tendency to inflammation. After this, the fever drink may be given, with the addition of an ounce of snake-root, and three drams of saffron and camphor, dissolved first in a little spirit of wine; the quantity of the nitre may be lessened, and these increased, as the symptoms indicate.

The diet should be regular; no oats given, but scalded, or raw bran sprinkled; the best flavoured hay should be given by handfuls, and often by hand, as the horse sometimes cannot lift up his head to the rack.

As drinking is so absolutely necessary to dilute the blood, if the horse refuses to drink freely of warm water or gruel, he must be indulged with having the chill only taken off, by standing in the stable; nor will any inconvenience ensue, but oftener an advantage; for the nauseous warmth of water, forced on horses for a time, pall their stomachs, and takes away their appetites, which the cold water generally restores.

Should the fever after this treatment increase, the horse feed little, stale often, his urine being thin and pale, and his dung sometimes loose, and at other times hard, should the moisture in his mouth continue, his skin being sometimes dry, and at others moist, with his coat looking staring, and surfeited; upon these irregular symptoms, which denote great danger, give the following balls, or drink; for in these cases there is no time to be lost.

Take of contrayerva-root, myrrh, and snake-root powdered, each two drams, saffron one dram, mithridate or Venice treacle half an ounce, make into a ball with honey, which should be given twice or thrice a day, with two or three horns of an infusion of snake-root, sweetened with honey; to a pint and a half of which may be added, half a pint of treacle-water, or vinegar; which latter is a medicine of excellent use, in all kinds of inflammatory and putrid disorders, either external or internal.

Should these balls not prove successful, add to each a dram of camphor, and where it can be afforded, to a horse of value, the same quantity of castor. Or the following drink may be substituted in their stead for some days:

Take of contrayerva and snake-root, of each two ounces, liquorice-root sliced one ounce, saffron two drams; infuse in two quarts of boiling water close covered for two hours, strain off, and add half a pint of distilled vinegar, four ounces of spirit of wine, wherein half an ounce of camphor is dissolved, and two ounces of mithridate or Venice treacle; give a pint of this drink every four, six, or eight hours.

A more simple drink, and perhaps full as efficacious, may be thus prepared:

Take camphor one dram, dissolved in rectified spirit of wine one ounce, then gradually pour on a pint of distilled vinegar warmed, and give for two doses. The quantity of camphor may be increased.

Should the horse be costive, recourse must be had to clysters, or the opening drink: should he purge, take care not to suppress it, if moderate; but if, by continuance, the horse grows feeble, add diascordium to his drinks, instead of the mithridate; if it increases, give more potent remedies.

Let it be remembered, that camphor is a very powerful and effectual medicine, in these kinds of putrid fevers; being both active and attenuating, and particularly calculated to promote secretions of urine and perspiration. It has been long celebrated in malignant fevers, as it gives motion to stagnant humours, in the most distant parts, and promotes their expulsion by the common outlets; nitre may be advantageously joined with it in many cases. These are the medicines that are chiefly to be depended on in putrid and epidemic fevers, where the circulation is slow and languid, the blood and juices tending to congregate, putrefy, and run into grumes.

A horse should drink plentifully to promote the operation of these medicines; but instead of them, to a horse of small value, give an ounce of diapente, half an ounce of

mithridate, and one dram of camphor, with a strong infusion of rue, scordium, and snake-root, in the manner as above directed.

Regard should also be had to his staling; which, if in too great quantities, so as manifestly to depress his spirits, should be controuled by proper restringents, or by preparing his drinks with lime-water. If, on the contrary, it happens that he is too remiss this way, and stales so little as to occasion a fullness, and swelling of his body and legs, recourse may be had to the following drink.

Take of sal. prunella, or nitre, one ounce; juniper-berries, and Venice turpentine, of each half an ounce; make into a ball with oil of amber.

Give him two or three of these balls, at proper intervals, with a decoction of marshmallows, sweetened with honey.

But if, notwithstanding the method we have laid down, a greenish or reddish gleet is discharged from his nostrils, with a frequent sneezing; if he continues to lose his flesh, and becomes hide-bound; if he altogether forsakes his meat, and daily grows weaker; if he swells about the joints and his eyes look fixed and dead; if the kernels under his jaws swell, and feel loose; if his tail is raised and quivers; if his breath smells strong, and a purging ensues, with a discharge of foetid, dark-coloured matter, his case may then be looked on as desperate, and all future attempts to save him will be fruitless.

The signs of a horse's recovery are known by his hide's keeping open, and his skin feeling kindly; his ears and feet will be of a moderate warmth, his eyes brisk and lively; his nose grows clean and dry; his appetite mends; he lays down well, and both stales and dungs regularly.

Be careful not to overfeed him on his recovery: let his diet be light, feeds small, and increased by degrees as he gets strength; for by overfeeding, horses have frequent relapses, or great surfeits, which are always difficult of cure.

This is the most successful method of treating these irregular, malignant fevers; where it is evident, by the various efforts nature makes to relieve herself, she wants assistance, and a spur to quicken her motions. For by the use of these warm medicines, a crisis, or termination of the disease is quickened and promoted, as appears by the alteration made both in the urine and skin; the former of which, by its thickness, shews signs of concoction, as it is called, or of a separation of the feverish matter from the blood; and the latter by its smoothness and glossiness proves that a regular and free perspiration is obtained: these two secretions are of such importance to the welfare of every animal, that the necessity of rectifying them, when disordered, is obvious from the consequences.

If this fever should be brought to intermit, or prove of the intermitting kind, immediately after the fit is over, give an ounce of jesuit's-bark, and repeat it every six hours, till the horse has taken five or six ounces; should eruptions or swellings appear, they ought to be encouraged, for they are good symptoms at the decline of a fever, denote a termination of the distemper, and that no further medicines are wanted.

The true reasons perhaps why so many horses miscarry in fevers, are, that their masters, or doctors, will not wait with patience, and let nature have fair play: that they generally neglect bleeding sufficiently at first: and are constantly forcing down sugar-sops, or other food in a horn, as if a horse must be starved in a few days, if he did not eat: then they ply him twice or thrice a day with hot medicines and spirituous drinks, which (excepting a very few cases) must be extremely pernicious to a horse, whose diet is naturally simple, and whose stomach and blood, unaccustomed to such heating medicines, must be greatly injured, and without doubt are often inflamed by such treatment.

From the experience we lately had of the epidemic cold and fever among our horses, and from the observations of others in the years 1732 and 1734, it evidently appeared that the simplest method of treatment succeeded best. Thus it is proper to bleed largely at first, to the quantity of three quarts, if the horse is full and strong: and if it appears that his lungs are not relieved by it, but continue stuffed and loaded, the bleeding should be repeated; and a rowel may be put in his chest or belly.

Dilute the blood with plenty of water, or white drink; let his diet be warm bran mashes, and his hay sprinkled. Should the fever rise, which will be known by the symptoms above described, give him an ounce of nitre thrice a day in his water, or made up in a ball with honey. Let his body be kept cool and open, with the opening drink, given twice or thrice a week; or an ounce of salt of tartar may be given every day, dissolved in his water, for that purpose, omitting then the nitre. After a week's treatment in this manner, the cordial ball may be given once or twice a day, with an infusion of liquorice-root sweetened with honey; to which may be added, when the phlegm is tough, or cough dry and husky, a quarter of a pint of linseed, or fallad-oil and the same quantity of oxymel squills.

As the kernels about the throat are greatly swelled in these cases, I need not mention the necessity of keeping the head and throat warmer than ordinary, to promote a freer perspiration, and forward the running at the nose, which in a horse answers the end of spitting, or expectoration in us: but the nose should never be syringed, as is sometimes done, to promote this discharge, which it often checks, and occasions bad swellings in the neighbouring parts and glands; for let it be remembered these are critical runnings of nature's own appointment, which by art may soon be frustrated. The following cooling purge it is very proper to give at the decline of the distemper, and may be repeated three or four times.

Take two ounces of fenna; anniseed and fennel bruised, each half an ounce; salt of tartar three drams; let them infuse two hours in a pint of boiling water; strain off, and dissolve in it three ounces of Glauber salt, and two of cream of tartar: give for a dose in the morning.

This purge generally works before night very gently; and in fevers, and all inflammatory disorders, is infinitely preferable to any other physic.

Before we close this account of fevers, it may be no improper hint to the curious, to take notice that a horse's pulse should more particularly be attended to than is customary, as a proper estimate may thereby be made both of the degree and violence of the fever present, by observing the rapidity of the blood's motion, and the force that the heart and arteries labour with, to propel it round. The highest calculation that has been made of the quickness of the pulse in a healthy horse, is, that it beats about forty strokes in a minute; so in proportion of the increase above this number, the fever is rising, and if farther increased to above fifty, the fever is very high.

How often the pulse beats in a minute may easily be discovered by measuring the time with a stop-watch, or minute sand-glass, while your hand is laid on the horse's near side, or your fingers on any artery; those which run upon each side of the neck are generally to be seen beating, as well as felt a little above the chest. *Bartlett's Farriery*, p. 31.

FEWEL, combustible matter; as fire, wood, coal, &c.

FIELD, a piece of ground inclosed, whether for tillage, or pasture.

FIELD HUSBANDRY. See **HUSBANDRY**.

FIELD scabius, a perennial weed common among the corn. It is all over rough and hairy. The stalk is upright, and often a foot or foot and a half high, spotted, and branching. The lower leaves are oval, and indented about the edges. Those which grow on the stalk are divided, and of that sort which botanists called pinnatifid. The flowers are blue, and of the compound kind, consisting of a considerable number of small flowers, each divided into four parts, and having one seed under them. The taste of the plant is a disagreeable bitter.

FIELD WELL. See **DRINKING-POOLS**.

FIG, the name given by farmers to a sort of wart on the frush, and sometimes all over the body of a horse. The figs that appear on the frush or sole, discharge a malignant stinking humour, which is very difficult to cure.

FIG-WORT, *pile-wort*, or *lesser centaury*, a perennial weed common in pasture-grounds. The roots consist of oblong knobs. The leaves are heart-shaped, cornered, and placed on foot-stalks. The flowers in general resemble those of the crowfoot, but differ somewhat from them.

them in having the cup divided into three parts only, the petals being about eight in number, and narrower. This low plant runs very much by the roots, and choaks all others which are near it.

FILLER, or *thiller* horse, that fastened immediately to the cart, and which supports the shafts.

FILLY, a female or mare colt.

FIMBLE-*hemp*, early ripe hemp.

FINE-BENT, the name of a very excellent species of grass found in great plenty on the best sheep pastures. We have given a figure of this grass on Plate XV. fig. 4. See the article GRASS.

FIRE-BLAST, an accident to which hops are very liable. See the article HOPS.

FIRE-BOTE, a quantity of fuel.

FIRING, an operation often performed on different parts of a horse. It is done in the following manner: when the firing-iron is red hot, the farrier applies the thinnest part to the horse's skin, in one or more places, according to the nature of the disease.

Firing, or cauterizing, is often necessary after strains and other accidents, which may occasion a long continued weakness, or where there is a fullness, and the part is grown hard and callous, especially about the joints, sinews, and nervous parts, those parts being composed of an infinite number of fibres and nervous threads, which lie so close together, that nothing but what is of the most powerful nature is sufficient to relieve them when obstructed. This is performed in the most effectual manner, by burning the outside, and giving vent to the inclosed matter to discharge itself; and sometimes proves beneficial, when all other helps have been found ineffectual.

In firing about the sinews and nervous parts, great care is to be taken not to go too deep at first, but by gentle repeated razes or lines, till they come to a pale red colour; for if the fire once touches the sinew, it will make the horse go lame as long as he lives: the same ought to be drawn pretty close together on each side the joints or sinews, following the course of the hair, without making of cross lines, which are of no use in these parts, and are only apt to disfigure the horse afterward.

When the more fleshy parts, or an obstinate humour, that cannot be brought to suppuration, requires firing, the skin ought to be pierced deeper, in order to draw away a sufficient quantity of matter from the part; the same ought to be performed upwards, to prevent any ulcerous disposition attending it: and in such cases little soft doffils of tow, dipped in warm basilicon, and spirit of wine, may be thrust gently up into the orifices.

The firing instrument, or knife, ought to be somewhat rounded on the edge, and gradually thicker to the back, sufficient to keep the heat of the fire for some time; the same should be rubbed clean, that no dirt or ashes may stick to it, and not used until the flaming redness is in part gone off. All the scared parts ought immediately to be bathed with spirits of wine, and where nothing else is requisite to complete the cure, the place is only to be anointed with oil and bees-wax melted together. *Gibson's Farriery*, vol. I. p. 251.

FIRING-IRON, a piece of iron about a foot long, one end of which is made flat, and forged like a knife, the back of it being half an inch thick, and the edge about the eighth of an inch.

FIR, a timber tree very common on mountainous and barren places, especially in the colder climates. It differs from the pine in having single leaves, which are, for the most part, produced on every side of the branches; whereas the pine has two or more leaves produced out of the sheath or cover.

Fir trees are raised from seeds taken out of their polypermous cones. The way to get out the seeds is, either by exposing the cones to a gentle fire, or by soaking them all night in water, which will cause their squamous cells to open, and readily emit their seeds. The former method is the best, provided they are not exposed to too great heat. But this ought not to be done until you are ready to sow them, which is best performed in the beginning of March.

These plants should be all raised in a nursery, where they may be protected from the birds, otherwise they will be in danger of being destroyed, when they first come up: for as they bring up the husk of the seed on the top of the plant, the birds in picking off the husk will break off the

plant, whereby a whole bed may be lost in a few hours; if they are not carefully guarded from them.

The best time of sowing these seeds is about the latter end of March, or the beginning of April, on a bed of light earth, covering the seeds about half an inch deep with the same sort of earth. In this bed the plants should remain until the following spring; when there should be a number of beds prepared in the nursery to receive these seedling plants; and the beginning of April they should be transplanted into the beds, at the distance of six inches row from row, and at three inches asunder in the rows: If the season should prove dry, it will be proper to water the plants every week once or twice, according to the warmth of the weather; and the beds should be covered with mats, to screen the plants from the sun, and drying winds, until they have taken good root; after which time they require no farther care, but to keep them clear from weeds. In these beds the plants may remain two years; at the end of which they should be transplanted into an open spot of ground, for their roots will in that time meet quite over the beds.

The distance which these plants should be planted in this nursery, should be four feet row from row, and two feet asunder in the rows.

When the plants are planted, if the season should prove dry, they should be watered, to settle the earth to their roots; and if this is repeated three or four times, if the season should continue dry, it will greatly promote their taking new root, and secure them from the injuries of the drying winds. In this nursery the plants may remain two or three years, according to the growth they shall have made; and, during this time, the ground between the plants should be constantly kept clean from weeds, and dug between the rows every spring; in doing of which, care must be taken not to cut or injure the roots of the plants: this is all the culture they will require during their continuance in the nursery: and, when they are transplanted into the places where they are to remain, the necessary care to be taken is, in taking them up, not to injure or cut off their roots, and let them be as little time out of the ground as possible; and, when they are out, to guard their roots from the drying winds. The surest time for removing of these trees is about the beginning of April; though they may, and often are removed with success at Michaelmas, yet the spring is the more sure season, especially in moist land.

Most of the kinds of firs may be removed at the height of six or seven feet; but those of two feet high are much better, and will in a few years get the better of those taller trees. *Miller's Gard. Dict.*

FIRS for cattle. Mr. Young in his *Annals of Agriculture*, vol. XIV. says "I was so pinched, last spring, for provender to cattle, that I had not a stone of straw, or a stone of hay, from the middle of March; nothing but whins and oats for horses, and fir tops (that is, tender shoots of firs) for cattle; I had 430 horned cattle, and about 120 horses, small and great, of which I lost but few (four or five, I cannot tell which) cattle; but there were numbers of cattle that died in this country for want. Some tenants lost the one-half of their cattle, and some almost the whole."

FISH-PONDS, reservoirs of waters, applied to the breeding of fish.

Fish-ponds are no small improvement of watery and boggy lands, many of which are fit for no other use. In making of a pond, its head should be at the lowest part of the ground, that the trench of the flood-gate, or sluice, having a good fall, may not be too long in emptying. The best method of making the head secure, is to drive in two or three rows of stakes about six feet long, at about four feet distance from each other, the whole length of the pond head, whereof the first row should be rammed at least about four feet deep. If the bottom is false, the foundation may be laid with quicklime, which slacking, will make it as hard as a stone. Some lay a layer of lime, and another of earth dug out of the pond, among the piles and stakes; and when these are well secured, drive in others, as they see occasion, ramming in the earth as before, till the pond-head be of the height designed.

The dam should be made sloping on each side, leaving a waste to carry off the over-abundance of water in times of floods or rains; and as to the depth of the pond, the deepest part need not exceed six feet, rising gradually in shoals

shoals towards the sides, for the fish to sun themselves, and lay their spawn. Gravelly and sandy bottoms, especially the latter, are best for breeding; and a rich soil with a white fat water, as the washing of hills, commons, streets, sinks, &c. is best for fattening all sorts of fish. For storing a pond, carp is to be preferred for its goodness, quick growth, and great increase, as breeding five or six times a year. A pond of an acre, if it be a feeding and not breeding one, will every year feed two hundred carps of three years old, three hundred of two years old, and four hundred of a year old. Carps delight in ponds that have marl or clay bottoms, with plenty of weeds and grass, whereon they feed in hot months.

Your pond should be drained every three or four years, and your fish sorted. If it is a breeding one, the smaller ones are to be taken out to store other ponds with, leaving a good stock of females, at least eight or nine years old, as they never breed before that age. In feeding ponds it is best to keep them pretty near of a size. *Mortimer's Husbandry, vol. I. page 290.*

FISTULA, a deep, narrow, and callous ulcer, generally arising from abscesses. See **ULCER**.

FISTULAR, **FISTULOUS**, an epithet applied by farriers to wounds and ulcers, which degenerate into fistulas.

FISTULAR, or *fistulous*, is also an epithet applied by botanists to leaves and flowers which are tubular, or that resemble a hollow pipe.

FLAGS, the turf, or surface of the ground, which they pare off for burning. See **BURN-BAKING**.

FLAIL, a well known implement of husbandry, used in threshing all sorts of corn. See the article **THRESHING**.

FLANKS, the sides of an horse. In a strict sense, the flanks of a horse are the extremities of his belly, where the ribs are wanting, and below the loins. They should be full, and at the top of them on each side, should be a feather; and the nearer those feathers are to each other, so much the better: but if they be as it were within view, then the mark is excellent.

The distance between the last rib and haunch-bone, which is properly the flank, should be short, which is termed well-coupled; such horses are most hardy, and will endure labour longest.

If a horse have a flank full enough, you are to consider whether it be too large; that is, if over-against that part of the thigh called the stifle, the flank fall too low; for in that case it is a great advance to purseness, especially if the horse be not very young.

A horse is said to have no flank if the last of the short ribs be at a considerable distance from the haunch bone; although such horses may for the time have very good bodies, yet when they are hard laboured, they will loose them.

A horse is also said to have no flank when his ribs are too much straightened in their compass, which is easily perceived, by comparing their height with that of the haunch-bones, for they ought to be as high, and equally raised up as they are, or but very little less, when the horse is in good case.

A horse is likewise said to have little flanks, to be sorrily bodied, to be grunt-bellied and thin gutted, when his flank turns up like a greyhound, and his ribs are flat, narrow and short.

A well flanked horse, is one that has wide and well-made ribs, and a good body. In this case the whole flank is used in the room of gut.

FLAX, the name of a plant cultivated both for the sake of its stalk and seed; the former being used in making linen, and the latter for oil.

The stem of this plant, which is round and hollow, grows to the height of about two feet, and then divides into several branches: these are terminated by blue flowers, consisting of five petals, and are succeeded by capsules divided within into ten cells, in each of which is enclosed a bright, slippery, elongated seed. Its leaves are long, narrow, sharp pointed, and placed alternately along the stem and branches.

The soil for flax should be a stiff loam, rendered fine by tilth, and situated in a valley bordering upon water; or such a soil as is thrown up by rivers. If there be water at a small depth below the surface of the ground, it is thought still better, as is the case in Zealand, which is remarkable for the fineness of its flax, and where the

soil is deep and stiff, with water almost every where, at the depth of a foot and a half, or two feet underneath it. It is said to be owing to the want of this advantage, that the other provinces of Holland do not succeed equally well in the culture of this useful plant; not but that fine flax is also raised on high lands, if they have been well tilled and manured, and if the seasons are not very dry.

It is justly remarked, in the letters which the Dublin Society have published on the culture of flax, that moist stiff soils yield much larger quantities of flax, and far better seed than can be obtained from light lands: nay, that the seed secured from the former way, with proper care, be rendered full as good as any that is imported from Riga or Zealand: but, as M. du Hamel rightly observes, strong land can hardly yield such fine flax as that which grows on lighter ground.

In the southern countries, the husbandmen who raise flax, sow part of their seed in September and October; so that the plants which spring from thence, remain of course in the ground all the winter; and this is a judicious practice in those places, because plants which have not covered the earth well before the summer heats come on, are apt to be parched by the heat and drought which usually prevail in that season. They sow linseed again in the spring; but the latter do not yield so large a crop: the flax, however, which it produces is more esteemed, because it is finer than that sown in autumn. M. Du Hamel seems, indeed to think, that the autumnal sowing yields the best seed; but however, that be, in places where the winter is apt to be severe, and where the flax, which is but a tender plant, would in course be in danger of being destroyed during that season, almost all the flax is sown about the end of March, or in the beginning of April. This spring flax is what we shall principally consider in this article.

It may be laid down as a general rule, that the land which is intended for flax should be brought to exceeding fine tilth by repeated ploughings, and that it should be enriched by a manure suited to the quality of the soil. Thus, when a pasture is broken up in order to its being sowed with flax, it must be well ploughed during eighteen months, or two years, before it will be fit for producing a crop of flax. To defray the expence of this culture, some other crops may be got off the land in the mean time, especially of such plants as do not occupy it long, and particularly of those which are remarkably benefited by frequent stirring of the earth whilst they grow; such as beans, pease, turnips, &c. because these repeated stirrings render the mould fine and loose, and help to kill the weeds, which would otherwise do great damage to the flax. The Memoirs published by the Society of Brittany inform us, that the Livonians, when they clear woodland, burn the wood upon it, then plough it, and in this state prefer it to any other kind of soil for flax.

If the land which is intended for flax be stiff, great care should be taken not to till it when it is wet, for fear of kneading it.

If the ground on which flax is to be raised has been long in tillage, it should be plowed deep before winter, and laid up in a very high ridges, in order that the winter's frosts may the more effectually moulder or loosen it.

In the month of February, if the land be not too wet, some very rotten dung should be laid in the furrows, and immediately covered over. In March, for southern countries, or in the beginning of April, where the climate is colder, another ploughing should be given to lay the land smooth, the clods should be broken by hand, or with the spiky-roller, and the seed should then be sown and harrowed in with a light or bush-harrow, so as not to bury it above an inch deep. If the soil be moist and cold, a little pigeon's dung may be sown with the seed, for it agrees admirably well with the flax: but this must not be done if the ground is very light and too dry. It will also be right to lay wet land out in beds thirty or forty feet wide, separated by deep trenches, to drain off the water, and convey it into the surrounding ditches.

Most of our linseed is brought from the North, namely from Riga and Zealand: but we may ourselves raise it very good, by conforming to the directions here given.

Linseed is reckoned good when it is large, oily, heavy, and of a bright brown colour. To know whether it be

oily, a few grains of it are thrown into a red-hot fire-shovel, and they in that case crackle almost instantly and blaze briskly. If it is sufficiently heavy, it will sink to the bottom of the water; and to judge whether it be new, a number of seeds exactly counted should be sown on the end of a hot-bed, and notice taken whether they all grow.

The best way of sowing flax, in order to obtain very good seed, is to drill it in equidistant rows about a foot distant, and then it may be hand-hoed, which will keep down the weeds, and improve the crop. But it is still better to drill the rows about twenty inches asunder.

The seed being smooth and heavy, is very proper for drilling, and in this way a very small quantity of seed sows an acre. The common allowance of seed sown broad cast is about two bushels and a half to an acre, oftener more than less; but drilled in rows at twenty inches distance, half a peck is sufficient for an acre.

Thick sown flax runs up in height, and produces fine soft flax; if sown thin, it does not rise so high, but spreads more, and puts forth many side branches, which produce abundance of seed, and such seed is much better filled, plump, and heavy, than the seed produced from thick sown flax. Nothing should be planted or sown between the rows, but the ground should be hoed with a hand-hoe, or small plough, taking care that none of the mould is thrown against the rows; to prevent which the intervals may be hoed with a triangular harrow, having a proper number of iron tines in it, and guided by two handles fixed behind. By these handles the tines are made to go deeper or shallower at pleasure; and if the intervals are cultivated with this instrument, beginning before the earth is become stale, and while the weeds are small, the land may be kept very clean, and in fine tilth, at a much less expence than by hand-hoeing: for one horse is sufficient for this work; a great deal may be done in a day, and by a frequent repetition of this hoeing, especially when the earth is dry, the weeds may be so effectually kept down, as never to rise much above an inch high. But the rows must be weeded by hand.

The flax thus cultivated is shorter than common, but stronger. It is not so subject as other flax, to be beat down and lodged in stormy weather, the stalks of it being fortified by the free admission of the sun and air among them; and there is sufficient room to hand-weed the rows, without lying upon, or treading down the flax, as in the common way of weeding.

It is usually reckoned, that in flax sown broad cast, the flax and seed are nearly of equal value. And it will no doubt be said, that by sowing it so thin, the crop of flax will be much lessened, which must be acknowledged; but the great object here is the quality of the seed, which will be incomparably superior to the seed commonly sowed thick; and if duly cultivated, in the method here laid down, will, in respect of the size and weight of the seed, excel either the Plantation or Riga seed. — In this way also, lighter land will produce better seed than in the common flax husbandry; because the earth that is kept in fine tilth; to any considerable depth, retains more moisture in dry weather, than soils of the same kind that is badly tilled, or suffered to grow stale and hard.

A change of seed is found necessary in cultivating some kinds of plants, particularly of wheat and some other sorts of corn, otherwise they are apt to degenerate. The necessity of changing seems to arise from the soil or climate: for which reason farmers choose to sow upon light land the seed raised upon clays, and other stiff soils, and the contrary, which they find of service; and the same advantage is found in some measure by a change of soils for flax seed. But this being a plant of nice culture, it seems most advisable, not to depend wholly upon a change of soil, even though the drilling and hoeing, as above, should still improve the seed in size and weight, beyond what is common in broad-cast sowing; but rather to sow, every second and third year, the best foreign seed, by which means, and the hoeing culture also, the flax farmer may be sure of having good seed every year.

When the goodness of the seed is known, more or less of it is to be sown, according as the husbandman intends either to raise a quantity of linseed for sowing, or to have very fine and soft flax. In this last case, the seed should

be sown pretty thick, in order that the plants may rise the closer together, and by that means grow slender and tall, which adds much to the fineness of the fibres of the flax. If the linseed is sown with an intention to let the flax remain for seed, a much less quantity of it should be used, that so the plants may come up thin, and thereby have room to grow to their full vigour and extent. As strong soils should be chosen for this purpose, it may perhaps be most advisable to follow the example of the judicious M. de Chateauvieux, in sowing it in drills, and horse-hoeing the intermediate spaces. He observed in his experiments, that the plants of flax thus raised yielded great plenty of excellent seed.

Some sow, with their linseed, either annual or perennial grass-seeds, when they intend to lay the land down for pasture after the flax is taken off. The plants grow but weakly under the flax, which, however, they do not hurt; but as soon as the flax has been pulled, they increase apace, to the great benefit of their owner.

Flax is sometimes damaged by insects when it is about three or four inches high. It is said that they may be destroyed by a slight strewing of foot, ashes, &c. At all events, it is certain that this dressing will give vigour to the flax, though it should not kill the insects.

If any weeds appear among the flax, as is almost always the case, they must be thoroughly rooted out; and that the flax may be as little damaged as possible in the doing of this the weeders should work bare-footed: they may indeed sit down upon the flax, for sitting upon it is found not to hurt it; but it would be greatly injured, if not killed, by being trod upon with the heels of shoes.

The finest flax is most liable to be laid, particularly in countries subject to storms. To guard against this accident, some people run across their flax field slender poles fixed to stakes: but a better method, and which was practised by the ingenious gentleman who directed the cambric manufactory at Winchelsea, was, to run small ropes across the field, both lengthwise and breadthwise; for these, being fastened where they intersect one another, and supported by stakes at due distances, form a kind of netting, which is proof against almost every accident that can happen from tempestuous weather.

Opinions are divided in regard to the degree of ripeness at which it is best to pull flax. Some think it should be pulled whilst it is green, in order that its fibres may be the softer and finer. Others, with the same view, pull it up before its seeds are quite formed; and others again think, that it should not be pulled till some of the capsules, which contain the seeds, have begun to open, being of opinion, that the fibres of green flax are too tender, and that they fall into tow. On the other hand, it is certain, that the fibres of flax which has stood till it is very ripe, are always stiff and harsh, that they are not easily separated from the reed, and that they do not bleach well. Here, therefore, as in most other cases, both extremes should be avoided; and it consequently seems most reasonable to think, that the properest time for pulling flax, is when its stalks begin to turn yellow, when its leaves begin to fall, and when its seeds begin to be brown.

As soon as the flax is thought to have attained a due maturity, it is pulled generally by handfuls: but as it is seldom all of an equal degree of ripeness, or of an equal degree of strength, it would certainly be advisable to pull first the ripest and strongest plants, and then the weaker and less ripe; for by this means they would at once be separated, which is of essential importance in the watering, because the weak and green flax requires much less steeping than the stronger and more ripe. All weeds, and the earth which adheres to the roots of the plants, should be carefully taken away, and then the handfuls of flax should be laid regularly on the ground.

The author of the judicious letters concerning flax, in the Dublin Society's Weekly Observations, seems to direct a too great degree of ripeness of the flax when it is pulled, and assigns as a reason, that it does not otherwise stand the force of the mill for scutching it. But as it has been found by experience, that the force of that mill is too great, and as a better method of performing this operation, in which the force can be suited to the strength of the flax, may soon be known, this great degree of ripeness will become the less necessary.

As the flax is pulled, it is laid together by handfuls, with the seed end turned to the south. These handfuls

should neither lie quite in a line with each other, not directly across, but a little slanting upwards so that the air may easily pass through them. Some, instead of this method, tie the handfuls of flax loosely at the top, then spread out their roots, and thus set several of them together upright upon their roots. In either of these ways, the flax is generally left twelve or fourteen days in the field to dry it. This drying is certainly not necessary for the rippling, because the ripple will separate the capsules from the flax as effectually before it has been dried as it will afterwards; and if it be done with a view to ripen the seed, it should be considered, that the flax will be more hurt by the longer time of steeping, which will become necessary in consequence of this drying, than the seed can be benefited; because the more the membrane which connects the fibres to the reed is dried, the greater must be the degree of putrefaction necessary to loosen and destroy the cohesion of this connecting membrane: the finer parts of the flax itself must necessarily be destroyed by this degree of putrefaction; and if the putrefaction does not arise to such a degree as to destroy the cohesion of this membrane, the fibres of the flax will adhere so strongly to the reed, that the force necessary in scutching will prove equally detrimental to the flax. The practice in some parts of Brittany, as we are informed by the Memoirs of the Society of that province, seems therefore much more rational; and this is, to ripple the flax after it has lain in the air two or three days; but even one day will be sufficient if the weather is dry.

If any flax is raised on purpose for seed, or if, through the dryness of the season, or the badness of the seed that was sown, the flax is come up very thin, so as manifestly to shew, that the seed which it may produce will be more valuable than the rest of the crop; in either of these cases, the flax should be let stand till its seed is perfectly ripe; thus sacrificing the flax itself to the then greater advantage of having good seed.

In order to ripple the flax, which is the next operation, a large cloth should be spread on a convenient spot of ground, with the ripple placed in the middle of it. The manner of performing this work is so well known, that there can be no need to describe it here. Its purpose is to obtain the linseed, which is always of considerable value, even though the flax has been pulled before its perfect maturity.

After the flax has been rippled, the seeds thereby obtained should be spread in the sun, to dry. Those which separate from the pods, of their own accord, are the fullest and ripest, and should therefore be set apart for sowing, in case the precaution of raising some flax purposely for seed has not been attended to. The pods, or capsules, are then broken, either by treading or by threshing, in order to get out the remaining seeds, the whole of which, as well as the former, should be carefully sifted, winnowed, and cleaned. When the seed is laid up, it must be frequently stirred, or ventilated, to prevent its heating. Even this second seed affords a considerable profit, by the oil which it yields, and also by being used, when broken, for fattening of cattle. The cakes of linseed, after the oil has been pressed out of them, are likewise found to be useful for this last purpose, though they are thought to render the fat of cattle yellow; for which reason it is advised not to give it them till within a few weeks before the beasts are to be killed. Their utility as a manure has been already mentioned.

As soon as the flax has been ripened, it should be carried with all convenient speed to the watering place. If care has not been taken before to separate the different kinds of flax, that separation must now be made: because, otherwise, some of the flax will be rotted in the water, before the rest will be sufficiently steeped.

The choice of the water for steeping it in, is thus very properly pointed out in the Directions for raising Flax, published by order of the Commissioners and trustees for fisheries, manufactures, and improvements, in Scotland.

"All flax ought to be watered in canals, which should be dug in clay ground if possible, because that soil best retains the water: but if a firm retentive soil cannot be got, the bottom or sides of the canal, or rather both the bottom and sides, may be lined with clay; or, instead of lining the sides with clay, which might fall down, a ditch may be dug without the canal, and filled with clay, which will prevent both extraneous water from entering, and the water within from running off.

"A canal of forty feet long, six broad, and four deep, will generally water the produce of at least an acre of flax.

"It should be filled with fresh soft water from a river or brook, if possible, two or three weeks before the flax is put in, and exposed all that time to the heat of the sun. The greater way the river or brook has run, the softer, and therefore the better, will the water be. Springs, or short runs from hills, are too cold, unless the water is allowed to stand long in the canal. Water from coal or iron is very bad for flax. A little of the powder of galls thrown into a glass of water, will immediately discover if it comes from minerals of that kind, by turning it into a dark colour, more or less tinged, in proportion to the quantity of vitriol contained in it.

"The canal ought not to be under any shade, because this, besides keeping the sun from softening the water, might render some parts of the canal cooler than other parts, and thereby make it water the flax unequally.

"The flax raiser should observe, that, when the water has been brought to a proper degree of heat by the sun, small plants will rise quickly in it; numbers of small insects and reptiles will generate there, and bubbles of air will rise up to its surface. If no such signs appear, he may conclude, that the water is not warm enough, or that it is otherwise unfit for flax."

Running water is not proper for steeping flax, because it prevents that degree of putrefactive fermentation which is necessary to separate the fibres from the reed; and besides this, in such streams, the flax is apt to be carried away by sudden floods, or to be filled with the mud and slime which those floods bring with them: but to have a small rill of water pass through the steeping place is very advisable, because it will supply the loss of that which is evaporated. Stagnant water, which is naturally of a bad colour, should likewise be avoided, because this communicates to the flax a colour which is not afterwards easily got rid of.

The flax, after it has been rippled and sorted, as before mentioned, should be tied very slack, with a band made of a few stalks, in bundles not larger than a man can easily grasp with both his hands, in order that the water may the more easily and more equally penetrate through them; and in this condition they should be put into the canal, somewhat sloping, or even half-standing upon one end, which, say the Edinburgh directions, should be the seed end, and consequently the root end uppermost; because, add they, (though I do not find it at all noticed by any other writers on the subject) when the seed ends are uppermost, there frequently breeds a great deal of vermin, destructive of the flax, and this, they assure us, is effectually prevented by putting the seed end downmost. However this may be, the flax, when put into the water, should be covered with straw, or fern, upon which a wicker hurdle and some stones may be laid, to keep it down, but without pressing too hard against the bottom. It is a common opinion, that if the flax is not thus covered, the sun will discolour it, even though it be quite covered with water.

More or less time is requisite for the steeping of the flax, according to the nature of the water, the heat of the air, and the greater or less degree of woodiness of the flax. It is steeped sooner with a south than a north wind: and that which has been pulled green is also much sooner steeped than that which has been pulled very ripe: consequently it is not possible to fix any precise length of time during which it should remain in the water. The way to know whether it has been steeped enough, is to draw a few stalks from out of the middle of the heap, and then try it: if the reed snaps short, without bending, and the bark parts easily from the reed, towards its point, the flax has been sufficiently steeped, and it must, in this case, be speedily taken out of the water, for otherwise it will soon become too tender, and begin to rot.

In some countries, the flax is steeped but four days, at the end of which it is taken out of the water, and the little bundle, or handfuls, into which it was before made up, are laid regularly side by side, till they have formed a pretty thick bed, upon which are then put planks loaded with stones. The flax is left in this condition four or five days, or more, according to the heat of the air; and its lying thus in a heap answers the intent of farther steeping in water: but as a great degree of putrefaction may arise in this operation, so much judgment and care are necessary, that I cannot think it an advisable method.

The Memoirs of the Society, which the states of Brittany have instituted, upon a truly judicious plan, for the improvement

ment of agriculture, arts, and commerce, inform us, in consequence of an account which the duke of Choiseul, minister of state in France for foreign affairs, received from the French ambassador at the court of Russia; to whom he had written on this subject; at the request of the society, that the Livonians use two sorts of places for steeping their hemp and flax; that the most simple of these are only holes dug near the side of rivers, and that the flax, or hemp, watered in them (which is very like the method practised in France) generally sells for from twenty-five or thirty per cent. less than that which has been steeped in the following manner.

When they would have flax or hemp of superior quality, they chose a spot where there is a fall of clear water, and there make, one under another, five, and sometimes six; basons or reservoirs, each of which is at least one foot, and at most two feet deep. The water can either be let run from one bason to another, or be stopped at pleasure. The basons are separated by slight banks of clay; and in each bank is a little opening, which may be closed whenever it is thought proper. To prevent the stream from overflowing the first bason, and afterwards successively the others, it is itself turned a little aside by a small bank of clay, and this bank is broken down whenever the water is to be renewed in the basons.

The Livonians put their hemp and flax first into the uppermost bason only. At the end of two, three, or four days, they remove it into the second bason, from thence into the third, and so on, till they have brought the several bundles of these plants down into the lowest. At each of these shiftings, the first bason is filled with fresh flax, and the water is renewed in all the basons. By this means, the steeping is not completed till the flax or hemp has passed through all the basons, and has remained a proper time in the lowermost, which is the last. Neither the English nor the Dutch import any hemp from Riga, but what has been steeped in this last mentioned manner; whereas a great part of that which the French receive from thence, is such as has been steeped in stagnant waters, in holes dug on the side of rivers.

When the flax is taken either out of the water in which it has been steeped, or from the heap above-mentioned, the bundles of it are spread out, like a fan, at the root end, and laid on a dry new-mown meadow, that it may dry, bleach, and become supple. It is there turned from time to time, and as soon as it is quite dry it is carried off: for otherwise the moisture of the dews and grass will have nearly the same effects upon it, as if it had remained longer in the water. This is evinced by the practice of those, who in some places, instead of putting their flax into water, only spread it on a damp meadow where the grass is somewhat long, leave it there all night, and in the morning, before the sun has dried it, gather it up in large heaps, and remove it into the shade, in order to spread it out again on the grass the next evening; and this is repeated till the flax is found to be sufficiently watered. In other places, it is watered by hand during the day, and so let it remain constantly on the grass. It is then let dry, and is afterwards housed. But, as M. Du Hamel rightly observes, this method is so tedious and troublesome, that, even if it should, as some say it does, give a little additional whiteness to the flax, yet the advantage in that respect is so small, as by no means to compensate for the inconveniences of the practice, which he therefore thinks is not advisable in any case, unless it be when the flax, after being taken out of the water, is found not to have been sufficiently steeped.

The disadvantage of laying the flax upon long grass, after it has been steeped, in order to dry it, is very justly pointed out in the Directions for raising Flax, published by order of the commissioners and trustees for fisheries, manufactures, and improvements in Scotland, when they advise the husbandman by no means to follow this method, because the grass, growing through the flax, frequently spots, or rots it. These judicious gentlemen therefore recommend short heath as the most preferable place for spreading flax upon, after it has been taken out of the water; and this the rather, because, when the flax is wet, it fastens to the heath, and is thereby prevented from being blown away by the wind, whilst at the same time the heath keeps it a little above the earth, and so exposes it the more equally to the weather: but grounds exposed to violent winds should also be avoided.

"The flax, continued they, when taken out of water, must be spread very thin upon the ground; and as it is then very tender, it must be gently handled. The thinner it is

spread the better, as it is then most equally exposed to the weather: but it ought never to be spread during a heavy shower, because that would wash and waste too much the bark, which is then excessively tender; though it soon after becomes firm enough to bear the rains, which, with the open air and sunshine, clean, soften, and purify it to the degree desired, and fit it admirably for parting from the reed: in short, after the flax has acquired a little firmness by being a few hours spread in dry weather, the more rain and sunshine it gets, the whiter and better it will be.

"The skilful husbandman, who follows this method, spreads his first row of flax at the end of the field from whence the most violent wind commonly comes, placing the root-ends foremost: he makes the root-ends of every other row overlap the seed-ends of the former row three or four inches, and binds down the last row with a rope; by which means the wind does not easily get below the flax, to blow it away: and as the seed-ends are seldom so fully watered as the root-ends, this over-laying has an effect like giving the seed-ends more watering.

"The flax is judged to have been sufficiently grassed, when it is of a clearer colour than before, when its bark is blistered up, when that bark parts easily from the reed; and when the reed is become very brittle: but no written description can possibly here convey a knowledge of this point, at all equal to that which is acquired by experience.

"The whole of the flax should be sufficiently grassed before any of it is lifted; for if a part be lifted sooner than the rest, that which remains will be in great danger from the winds.

"A dry day should be chosen for taking up the flax; and if there is no appearance of high wind, it should be loosed from the heath or grass, and let loose for some hours, to make it thoroughly dry.

"As a great quantity of flax can scarcely be equally watered and grassed, and as its different qualities will best appear at lifting it off the grass, each different kind should then be collected together, and kept by itself; that is to say, all of the same colour, length, and quality.

"The smaller the bundles are into which the flax is made up, the better they will be for drying, housing, &c. and in making up these bundles, as in every other operation upon flax, it is of great consequence that all the stems be laid together as they grew, that is to say, root-ends to root-ends, and seed-ends to seed ends."

The Livonians, say the before-quoted Memoirs of the Society of Britany, cut off the roots of their hemp, but not of their flax, when it is taken out of the steeping basons above described. They then tie the flax or hemp up in bundles about as thick as the lower part of a man's thigh. These bundles are placed upright, and supported by a stake, around which a few of the tops of their stalks are twisted, the better to secure their standing. They are left in this situation one day, to drain; then they are spread upon the grass for one or two days, and after this they are laid in heaps, and covered over with haulm, stubble, straw, or some other such like covering, to make them sweat. When the hemp or flax has sweated enough, it is laid in heaps in the shade, and there dried: but these heaps must not be so thick, but that the air may penetrate a little into them. It is on this last operation that the good or bad quality of the hemp or flax thus managed chiefly depends. Both of them may be kept two or three years, and even longer, upon their reeds, after they have been prepared in the manner above directed; and when it is intended to break them, after this keeping, they are put into an oven properly heated.

In the common way, after the flax has been grassed, it must be dried by heat, to make its reed break readily, and separate the more easily from the bark. To guard against the danger of fire, this business is frequently performed in a place distant from any other building. The caverns, or hollows under hills, or rocks, before described for drying hemp, are also very proper for this purpose.

There are two general ways of drying flax. Some place against a wall, upon uprights and cross pieces, a hurdle of which the bars are small, and about two inches asunder, and upon this the flax is spread four, five, or six inches thick: a small fire, made of broken reeds of flax, is cautiously kindled under it, and care is taken to turn the hemp from time to time, that it may dry equally in every part: the flax-dresser takes off only that part of it which is at the side of the hurdle next the wall, then pushes the rest forward into its place, and fills with fresh flax the vacancy thereby made at the fore-part of the hurdle. This operation

tion should not be entrusted to any but a very attentive person, because, if the flame should be suffered to rise too high it would set fire to the flax. It is true, indeed, that this seldom happens; and when it does, the loss is not great, because but a small quantity of flax is laid together on the hurdle. Some say that the smoke of the fire thus made of the broken reeds, hurts the colour of the flax, and that this lessens its price when it is sold; but that the quality of the linen made of it is not at all the worse, this discolouring being easily removed by bleaching.

The other method of drying flax is by putting it into a hot oven. The Livonians make their ovens, for this purpose, either of clay, brick, or hewn stone. Those which are built with clay, are sometimes large enough to contain eight hundred bundles at a time: but it is more common to make them for only two, three, or four hundred. They are shaped like the ovens for an army, that is to say, they are very high arched. They require no greater degree of heat, which is given with dead wood, furze, broom, &c. than is just sufficient to render the reed of the flax brittle; and the same of hemp, for the Livonians use them for both these plants, the bundles of which they set upright in them, and as soon as they take them out of the oven, they carry them to a kind of mill to be broken.

The Dutch build their ovens for drying flax within a large capacious chimney at the end of the building where the breakers and scutchers work. The usual dimensions of this building, which is well lighted, are, in the clear, thirty feet by fourteen; but it is sometimes larger where great business is carried on, though seldom, if ever, less. The dimensions of the oven here generally are fifteen feet in depth, ten in breadth, and five feet in height: its roof is arched, its entrance, which is just large enough to admit a man with tolerable ease, is made to shut close with a wooden door. This oven is not heated with wood, excepting at the very first; for after the workmen have begun to dress the flax, the broken reeds, and other refuse parts which are beaten off it, and swept up, suffice to continue the heat; so that each parcel affords firing for the next, till the whole is dried. The Dutch kindle the fire in the oven some hours before the day's work is over. The sweepings of the flax light easily, and the oven heats and cools again sufficiently before the breaking, and scutching is finished. They fill it when they leave off work; and the next day when they return to it they find the flax dry and ready for breaking. The flax breaks best and most easily when it is a little warm and crisp: and consequently the working it then is cheapest and most advantageous; and accordingly the Dutch never draw two bundles together from the oven, but take them one by one as they want them. It will, perhaps, be needless to observe, that when the oven is heated, it must be well cleaned before the flax is put in; for the least spark will set the flax on fire, and this would be a considerable loss, as the ovens hold a large quantity.

The famous M. Tschiffeli, of Berne, in Switzerland, has obliged the public with a Memoir on the Culture of Flax, the substance of which we shall lay before our readers.

In his direction for the choice of seed, he says, it should be of a bright shining brown colour, not flat, but thick and plump; should crackle much when cast on live coals, and should sink to the bottom almost as soon as thrown into water.

With respect to soils, this writer observes, that any may do for flax, provided it is not too wet, or too stoney, and has not too much sand or gravel mixed with it: some however, are to be preferred, particularly black earth, neither too strong nor too light; and, in general, strong land is to be preferred to light.

To prepare grass-grounds and pastures for sowing flax, M. Tschiffeli lays down the following rules:

The land should, by the end of July at latest, be turned up in small furrows, about two inches deep. Early in the month of September, a heavy harrow should, in dry weather, be drawn over the field, in order to pulverise the soil; and the month following, if the land is not in great heart, it should have a good dressing of dung, which being first regularly spread, should, in dry weather, be ploughed in to the depth of six inches at least, with narrow furrows, leaving the field rough all the winter.

In the following spring, this gentleman observes, that as soon as the ground is dry, the land should have a good harrowing; and about the middle of April, which is in Switzerland the season for sowing, it should, in dry weather, have its third ploughing, somewhat deeper than the second; and if the weather should not immediately afterwards be favour-

able for sowing, the land should the same day be harrowed down smooth.

When flax is to be sown on a fallow, the three usual ploughings are to be given, observing only, that every ploughing is deeper than the last; and the dung should be buried by the last, leaving it rough during the winter, and managing it as above in the spring.

When flax is sown the second year after a fallow, the land being dunged the preceding year, and in good heart, no manure will be necessary; but immediately after harvest it must be ploughed about two inches deep, to prevent the weeds from growing and impoverishing the soil. As soon as any weeds afterwards make their appearance, it must be well harrowed with heavy harrows, and about Michaelmas should be ploughed in narrow furrows, about six inches deep, lying rough during the winter season. The following spring the ridges should be harrowed down, and afterwards laid smooth with smaller harrows, being in April ploughed for the last time.

Flax, M. Tschiffeli remarks thrives best upon land that has the preceding year borne a crop which shaded the ground, and prevented the weeds from growing; therefore good flax is seldom got after rye.

This writer very justly observes, that the quantity of seed to be sown should be proportioned to the nature and condition of the land, never less than two, nor more than three bushels to the acre. Light land should be sown earliest, but always after the dread of white-frosts is over, and never in rainy weather, or when the ground is wet; a mild day is best for this purpose, when the wind is not in the north-east, and dew may be expected in the evening.

It is best, our sensible husbandman says, to begin to plough for sowing after noon, the harrow following close at the heel of the plough. A little before sun-set, the seed is to be spread, best at three casts, and the work left in this state till the next morning, when, without fail, the seed must be covered with light harrows, or strong rakes. If the soil is rather light, and the spring likely to be dry, it will be best to roll the land; and if it was not manured before the winter, some very rotten dung may be spread after the seed is harrowed in, and before the field is rolled.

It is better to use no dung at all than that which is not well rotted: foot and ashes, hogs or cows urine, are good manures for flax, or in fact almost any thing that will not carry weeds on to the land.

When flax is grown to the height of about four inches, it may safely be weeded; but the precautions taken in Switzerland on this occasion are worth notice. There the work is carefully executed, but with as much expedition as possible, the weeders going bare-footed into the field, and working as much as they can, either sitting or lying down, heaping the weeds, and carrying them away every time they leave off working. The weeders should also, if possible, always face the wind, by beginning at the corner of the field to which the wind blows, as in this method the flax will rise the sooner: and the work should never be done in rainy weather, or when the ground is wet.

If the flax is to be propped, the best time to do it is at the time of weeding. To prop flax is to fix supporters, about the size of a man's finger, branched a little at the top, and about three or four feet long, at the distance of every three feet.

Flax should be pulled in dry weather, in general, when the foot of the stalk begins to turn yellow, though the seed should not be quite ripe. If the crop is not all of equal ripeness, the ripest should be separated; as if all were to be grased together, the unripe part would be rotten before the other was sufficiently grased: it is also best to pull, though at one time, the longest separate from the shortest. When it is all pulled, it must be spread on grass-ground, or on a stubble, the crop end of the stalk being laid to the south, that the seed may ripen the better.

M. Tschiffeli is of opinion, that when the quantity is large, it is best to separate the seed by threshing as soon as it is got in, in the following manner. The beds must be made pretty thick, the crop-ends of the stalk touching the wall of the barn; and over the feet of the stalks a heavy plank is to be laid, to prevent the flax from being scattered about in threshing. The wall, by confining the workmen, will prevent them from striking too hard, and thereby damaging the flax.

If the quantity of flax is small, it may be rippled in the ordinary way, observing only that the handfuls be not too large. When the seed is separated, it must be laid on a cloth, exposed

posed to the sun for several days; and afterwards it should be kept in a very airy place; but must be stirred every two or three days for three weeks. It may be kept in this condition two or three years, without the least damage; but when once this seed is deprived of its capsule, it will scarcely ever keep above a year.

When the flax has been rippled, it must again be laid, but thinner than the first time, on a grass-field that has been about a fortnight before mown, being spread, if possible, in dry years on damp ground, and in rainy years on dry land, but never on wet meadows. It must at this period be carefully turned every other day, if the weather is wet, or the dews heavy.

The time the flax is in grassing, depends on the coarseness or fineness of the staple, the heat and the cold, dryness and wetness of the weather; but if, in bruising betwixt your fingers, the top of the stalk when it is dry, the harle or bark separates easily from the woody part or boon, and this last is not tough, but brittle, the flax should be taken from the ground, in order to be carried under cover as soon as it is dry.

The best method of drying flax for braking, this accurate writer says, is to dig a hollow place in the earth, two feet deep, three wide, and from twelve to fifteen feet long, lining it with stone, over which, at the height of about four feet, is fixed a griddle, or grating, consisting of small poles, securely made fast to four or six piles, or stakes, driven into the ground.

The most proper fuel, we are told, for drying the flax, is either charcoal, or well-dried turf, as well because they give an equal degree of heat, as on account of their not producing much of either flame or smoke.

When the workmen begin to brake the flax, they must go on briskly; for it should be done whilst it is hot from the grating, and should be effected by an equal motion, beginning at the crop-end.

In this manner does the sensible and patriotic Mons. Tschiffeli say that flax should in this country be cultivated and managed; and, if we are not greatly mistaken, the method might, with very little variation, be to advantage adopted in the British islands.

As different countries have different methods in cultivating the various productions of the earth in general, so those relating to flax, in particular, are greatly diversified. We have, therefore, given under this article every thing we thought worthy the reader's attention. The following is the method practised in the Mahera, a district of the county of Roscommon in Ireland; and was wrote by Mr. John Irwin, a gentleman who has long cultivated flax there with success.

Of the Cultivation and Management of Flax in the Mahera.

The poorer sort of people in the district I live in, are so indigent, that they are almost in a state of slavery. Indeed, within these last forty years, they have much recovered from their bare and naked condition, owing in a great measure to the considerable extension of the linen manufacture.

Their chief riches consist in their annual crops of flax, corn and potatoes, in order to pay their rents, which they help off with day-labour; a most galling article to them; for, as to cattle, few of them have any, or but a milch-cow or two at most, which are appropriated for nourishing generally a numerous issue. The calves, which industry ought to be let remain with them to increase their funds, or to clothe their families, a rapacious landlord seldom wants a pretence of appropriating to himself. These people then, from necessity, it is evident, must be perfectly versed in the cultivation of flax and potatoes; and they would succeed very well as to corn, had they surmounted a few old prejudices respecting the form or make of their implements, and the methods of using them. It is, however, from ocular knowledge of their proceedings, in my work and their own, that what I now communicate to you is founded.

The soil about Oran, being strong, deep, and moist, with a clayey loam mostly at bottom, yields excellent flax. It is here scarcely ever produced immediately from the ley. The general practice is as follows: a parcel of ley land in good heart, that is, which has not been ploughed for many years, is proclaimed to be set to grass potatoes (otherwise spaddane, a very mistaken practice, especially

if a deep soil, if not to be sanded, or if a light, if not marled, or otherwise manured) for this land the poor are charged from three pounds to five pounds per acre, sanding not always included: a most unconscionable price!

They generally bargain for two successive crops; and it is for their benefit, as also for that of the land, to have it sanded, because it strengthens it the better to stand a continuation of tillage, and to come the sooner to turf, and yield a good coat of grass, when let back into the ley; but the sky-farmers (those who hold at rack-rents) are mostly so greedy for gain, that it is with reluctance they agree to sanding, as it abates fourteen shillings per acre of their price. When land that requires it is not sanded previous to this kind of tillage, it is doing it great prejudice; but farmers are not always solicitous about this matter, especially on short leases.

Land properly set in this way ought to be sanded at least a year before setting, that it might have proper time to penetrate into the earth, and impregnate it with its salts; but they are such bad farmers about me, that they set, sand, and plant their potatoes almost at the same time. Even in this bad away the land should be set and sanded (or otherwise manured) at least in November, and the potatoes planted the March following at farthest: but I have seen land not sanded till March or April, and not sowed till towards the end of May, (a palpable blunder;) yet this land has yielded a tolerable crop, owing to its great natural fertility; for the sand becomes of little use, if the land is turned up soon after it is fresh laid on. This does much hurt in the country; for such land, after it is let out for a long series of tillage, (suppose fifteen years) is a long time recovering itself, and that which is spaddanized out of the ley, and not gravelled at all, unless of a most superior rich kind, is doubly injured.

The potatoes should be dug towards the end of October, or beginning of November at farthest, (frosty weather excepted) to make room for a crop of bere, or a crop of flax, the spring following; if for flax, the land should get a deep ploughing before Christmas, to benefit of the winter manure, such as frost, snow, air, &c. and a cross ploughing in the beginning of February; and towards the end of March, it ought to get another ploughing in the track of the first; then the ridges to be harrowed down as fine and as flat as possible, and the seed sown in, and lightly covered with another gentle harrowing; for the seed is not apt, from any cause that I have observed, to be disturbed in the ground.

In this situation it should be left till June, then weeded. Some weed it when four or five inches high; but treading it so young hurts it; and this weeding is of no use, for it must be weeded again before pulling, especially in deep chiltern countries, where weeds get a head much more than in light gravelly soils. In these the flax is always shorter and finer, and the seed in less quantity; but the Irish seed, thought it is often imposed for foreign, is never so good: for example, the first year's return of foreign seed will produce a middling good sort of flax, whereas the second return will not. To sow the seed even should be most carefully attended to: a commonly skilful hand will with ease cast it properly, the method being so well known. Sixteen pecks of seeds at twelve quarts to each peck, is a proper quantity for an acre of good light soil. In my deep grounds I have known fourteen pecks to be sufficient.

The seed now much used in Ireland is the Plantation, but the better sort of the Baltic or Riga seed I would prefer. The Dutch agrees worst of all with our climate. The choice of it is easily known. The women are surprisingly skilful in every thing that regards this plant: one of them will shut her eyes, put her hand into several hogheads of flax-seed, and fix upon that which is best; but they have marks from pressing it to oil between their fingers, so as to observe the edges, and from taste, smell, and view, without requiring to make the other common experiments; whence they are seldom deceived; not but the merchants play them a thousand tricks in this article, which is become very lucrative of late years, from the vast demands there are for it.

The heavy, pale reddish, or rather clear brown looking seed, being thick and short, and oily in the feel, is the best. Sometimes, among some parcels of the seed, there are certain mixtures, by which predications the women immediately estimate the quality of it. The old Irish seed, of which quantities are still sown, is the worst of all; the

returns are extremely bad, and the flax but indifferent for use.

Two crops successively are common in deep rich lands; but as flax is a great drawer, they are not the better for it, as it greatly retards their coming to grass.

We always sow flax after potatoes or corn, (bere) and, if proper care be taken in the preparation of the land, find it to answer well. How far better it may be immediately out of fresh land manured, I will not take upon me to say: some writers recommend this method; but it would never answer with our poor people. I have seldom known flax to be raised immediately from manured grounds: mine being rich, deep, and moist, and properly wrought to return a first crop of some other article, yields afterwards admirable flax. Where different soils can be had in the same district, it is needless to observe, that the richest and strongest, with a clayey loam at bottom, is best: the nature of this plant requires such, being a great drawer of the nutritive parts of the earth; but, on the other hand, there is a medium to be followed in this, as in most other things: land may be made too rich for flax, which will undoubtedly lodge it, that is, occasion its prematurely lying flat to the ground: this prevents its ripening, consequently occasions great waste of it, total loss of seed, and what is recovered of it manufactures but indifferently, and stands the tests of use worse: however, there is much of this sort spun into yarn by the poor, and imposed for good on the eagle-sighted yarn-buyer, notwithstanding his great vigilance.

If middling good land, whether in the ley or not, be fallowed early in the summer, and gets the proper tilth till the March following, when it is to be sown, there is no doubt but it will yield an excellent and abundant crop of flax. Land cannot be ploughed too often, or made too fine, for this purpose. Flax ought to be sown and pulled in dry weather.

It is not ripe in my neighbourhood, generally speaking, till the beginning or middle of August, and sometimes later, when late sown: the better sort of husbandmen think it is not necessary to sow it earlier than Good-Friday: about that time most people begin.

The poor people have several marks by which they know when it is fit for pulling: the degree of brownness of the colour is the chief, and is a sufficient guide to any person. The men and women, promiscuously ranged in a row a breast, pull it expeditiously enough, especially if they are a little refreshed with some of the good things of this life, and lay it on the swarth. If there be danger of rain, they bind it the same evening into sheaves, and stack it, putting commonly eight sheaves in every stack. Here it is suffered to remain for some days, till it is sufficiently dry to remove.

The poor, from necessity, proceed to manufacture it immediately, by rippling of the rows, and watering it, &c. But my method is as follows. After I let my flax sufficiently season in the field, so as to prevent the danger of heating, which destroys it, I draw it into my haggard, stack it, and thatch it well. Thus I let it remain till the next sowing time, (March) when I ripple it and water it, and, if I have leisure, proceed to dress it; if not, make it back into a stack, and let it lie so, without any hazard of danger, as long as convenient: or, (another way) soon after pulling, it may be rippled, watered, and stacked, so as to be ready for dressing the spring following. But I chuse the former method, because I thereby preserve the seed, and sell it, if I take a little care, equal to the foreign, which will go a good way in reimbursing me my expence: it is true the quantity of flax will be somewhat diminished for remaining so long unwatered; but then it makes ample amends in meliorating it; for I have observed, that the flax thus managed dresses and manufactures much better, and when in linen, it wears best. But the impatience of our Irish ladies, who are the conductors of this branch, from the time the flax is over ground, till made into linen, is such, that they do not relish delays of this sort, though infinitely the best method of proceeding.

For watering flax, clear stagnated pools or canals, or ponds, are best, provided there are no fish, as it kills them: springs and running-waters must be avoided. To sink it under water is proper, and let it lie about three weeks, more or less, according to the quality of the flax, and the condition of it at putting in.

About me, the poor people still preposterously will water it

in bog-holes, because they think the water cannot be too soft, and that the banks being unincumbered with long grass, facilitate the drying of it.

When it is brought home (as they have no ovens) they fix a large hurdle horizontally by a ditch side about four or five feet from the ground: on this they lay a parcel of flax, and underneath make a large turf fire, and keep constantly turning it.

They judge it fit for the brake, by rubbing a parcel between their hands, and finding the prickles to detach themselves easily from the flax.

The braking is a very laborious part: it is pity that about where I live there are no engines contrived for this purpose, as it would save great expence in labour. This part of the process ought, properly speaking, to fall solely to the share of the men; but the women as commonly do it, which I think very unseemly, and still more so to see a man scutching and hackling flax, which is equally as common with us: but the women always scutch mine, and I find do it best, as I order them refreshment, it being merry-making time, (though but short) like vintage, or sheep-shearing time.

The construction of the brakers I need not explain; they are simple engines, and known to every body. The broad scutch is best, as it hurts the flax less: it ought to be made of well seasoned oak, to be light, that the women, who are dexterous at it, may manage it more easily.

A great deal depends on the skill of the hackler, who ought to be very expert and knowing in dividing it properly, and in arranging the sorts according to their different fineness. I have had some hacklers manage this matter so well, that out of the very tow they produced I had good linen for common use. I had other hacklers, who, instead of preparing my flax to spin to eight or ten dozen of yarn to the pound, of which it was capable, prepared it so badly, as to produce me only from four to six dozen yarn.

To the spinners we keep in our houses we generally give from thirty-five to forty shillings a year: these spin from four to eight dozen yarn; but if they spin finer, they are entitled to get a gratuity in addition, or higher wages. There are girls in plenty in the north of Ireland (where the manufacture most flourishes) who spin surprisingly fine, and many of them with both hands at once, at wheels adapted for the purpose; but scarcely any of these ever come into the parts where I live.

As to the rest, from the time the yarn is sent to the weaver, till it is brought home from the bleach fit for use, it forms a particular process in itself, and shall be communicated to the public, when more ample leisure will permit. However, before I dismiss this subject, it may not be improper to make a few detached observations to illustrate still more what I have already said.

There are various ways to know good seeds, which is one of our most essential objects. First, to discover its thickness, by taking some grains, and squeezing them between the fingers, until the white edges of the inside pulp or grain are forced to appear. To estimate its goodness by its weight may be easily done, by throwing a handful into water, and if good it will sink quickly. To prove if it be oily, throw a handful on the fire, and if, as soon as it touches the coals it burns up and crackles, its goodness may be depended on. But no seed of Irish growth, as I said before, will thrive well a second year in any of the soils in my neighbourhood; nor will the same soil answer for more than two successive seasons, without the intermediate occupation of other crops procured from manures.

As the culture of flax lays down land very smoothly and well, if you chuse to have your land let out, you may sow grass-seeds with a light roller, or bullock, in some little time after your flax is in the ground: they will not hurt it; and by this means you will have a full coat of grass the same season, which otherwise perhaps would not be the case for two or three seasons, flax being a great impoverisher.

When the flax is a clear yellow, or a clear brown, something resembling a lemon colour, and begins to drop its leaves, it should be pulled; but never when it is green, though often done, which is a very destructive method, for in this case it loses considerably in quantity and quality both with respect to flax and seed. Those who imagine pulling it green will make it yield the finer linen are mistaken:

taken : they need only consult the method of the Flemings, who suffer it to remain the longer in ground, the finer they want it to prove for their laces, cambricks, &c. Care, however, should be taken not to let it remain too long in ground, as this makes it work badly, yield bad yarn, and not bleach so well.

I have kept my flax in stack in my haggard some two or three seasons, and never found it was damaged by vermin, though I know there are preventatives laid down by some writers for this purpose.

If the season be moist, there is no stacking it with safety, till it remains unheaped a considerable time in the barn, as the least heating is certain destruction to it.

No land can be too good for flax, if the seed be duly proportioned to it. If the crop fails on a rich and strong soil, it has too much seed ; for it should not be so thick, but that every stem may have the benefit of the sun and air to fortify it. *Museum Rusticum*, vol. I. p. 5.

Mr. Young, in his *Annals of Agriculture*, vol. xiv. p. 349, says that "Flanders is justly celebrated for the culture of flax ; it is there cultivated in great quantity, and is considered one of the most considerable agricultural revenues of the country. They have a particular way of sowing flax, which, in the French language is called *lin ramé*, and which as it seems to me interesting, I will give you some account of : the land for the *lin ramé* is ploughed, and manured before winter ; and in the beginning of March, or sooner, according to the season, it is deeply ploughed again : some days before sowing it, they spread upon the land some pigeon's muck, and afterwards the seed, which they cover with an harrowing, and a rolling. When flax comes up, and is four or five inches high, they first weed it with the most scrupulous attention, and then they build a kind of cover hanging over the little plants in the following manner: they stick on both sides of the ground, bordering the ridge, some strong wood forks, about six inches high, upon which they put long poles along the width of the ridge, in a direction parallel to the ground. These poles are crossed by small sticks, branches of trees, &c. so as to form a kind of grate full of holes, through which the plants of flax pass, as they grow higher : by these means, their stems have a good defence against winds and rains, and their roots against an excessive humidity and heat, and so their vegetation is very much benefited. The produce of the *lin ramé* is very great ; when it succeeds well, the crop exceeds in value the land where it grows : I have heard of such crops of flax, so cultivated, as to be almost beyond credibility."

A Short Account of the Advantages of the new Machinery for braking, scutching, and beating Flax and Hemp, invented by Robert Macpherson, Assistant-Secretary to the Commissioners and Trustees for Improvements in Scotland.

The breaking of flax by the Dutch hand-brake (which is the best old method of breaking) the scutching with stock and hand, and beating with hand-mallets, being laborious, tedious, expensive, and requiring many hands, it was thought a valuable improvement, when, some years ago, a water-mill was invented, by which these operations are performed with more ease and expedition. But in some parts of the country, a sufficiency of water and water-fall is not to be met with ; in other parts where these are to be had, lint-mills are not erected, on account of their heavy expence ; and wherever erected, they are found liable to the following inconveniences. First, the expence of fitting up the mill, making dams, the aqueduct, &c. and keeping these in repair, is great ; and much damage happens by fire, and by water floods. Secondly, in Scotland, it has hitherto been found, that on account of the scarcity of hands, and difficulty of dressing in the old hand-methods, flax never was raised in considerable quantities, until the country people found the convenience of a mill in their neighbourhood ; and therefore the first sitting-up of a mill in a part of the country where there was none before, could not for years expect business adequate to his out-lay of money. This circumstance obliged the linen-board in Scotland to defray part of the expence of fitting up many of these mills. Thirdly, this mill is extremely dangerous to the workmen ; many have lost arms by it, some their lives, and the nature of the work there is otherwise remarkably unhealthy. Fourthly, this mill is so con-

structed, that the stroke of its scutchers is ineffectual, unless they are moved with a degree of violence, that nothing less than the utmost dexterity and closest care can prevent from destroying a very considerable part of the flax ; and as that skill and unremitted attention cannot be expected among a number of common day-labourers, the great waste of flax always attending these mills is easily accounted for, especially as unskilful hands are often employed ; for being called to this work only in winter, the lint-miller must content himself with labourers that, at the beginning of the season, are not otherwise engaged. Fifthly, The carriage of the rough flax to mills at a distance, the delay there, sometimes for months, till others be served, during which time the flax must lie without doors : damage, embezzlement, &c. these are much complained of ; and, with the waste before-mentioned, have in general ruined the character of these mills. Sixthly, The expence of flax-dressing is still kept high, because the proprietor of the mill must have a large rent, especially as his outlay upon it is extensive ; the miller must have a living ; and the workmen extraordinary wages for such dangerous and unhealthy work. In short, it has become very doubtful, whether, upon the whole, these mills have not been more hurtful than beneficial to the manufacture.

The new water-mill for dressing flax and hemp, invented by Robert Macpherson, removes part of these inconveniences. For, 1. It is much less wasteful of the flax : as much so, it is presumed, as water machinery can possibly be. It not only yields more flax from the scutch, but the flax, dressed by it yields still more from the heckle. 2. It is fitter for dressing long hemp. 3. It is no way dangerous nor unhealthy to the workmen. 4. It requires a less expensive mill-house, and less annual repair. 5. It requires much less water. 6. For one, two, or a few workmen, the parts of its machinery which dress the flax or hemp, may be joined to the movement of a corn-mill, or any other mill, by a small iron-axle, or by rope and pulley, through any wall or partition, at a side, above, or below.

Where much business in the beating way is to be done, the new machinery with water or a horse, gives entire satisfaction. But scutching proves an operation that requires more judicious management than can be expected at a public water-mill. A lint-miller, who dresses flax for others, finds his profit in the dispatch made by the great velocity which can be given to the scutchers by a power of water ; but the proprietor of the flax loses more by the waste occasioned by that velocity than the miller gains by the greater dispatch. In short, the dressing of flax by any expensive public water-mill remains still liable to many of the inconveniences mentioned in the first part of this paper.

The foot-machines (likewise invented by Robert Macpherson) it is presumed, obviate all these inconveniences, and go far towards bringing flax-dressing to perfection. For, 1. They waste the flax or hemp as little as the hand methods of dressing. 2. They are much more expeditious, and as much so as dare be attempted without destroying a considerable part of the flax or hemp, which above every thing else ought to be avoided. 3. The working with them is not so laborious as the hand methods. 4. They are not dangerous to the workmen. 5. They are not too bulky for general use : they are portable upon a cart, are of small expence, simple construction, can be made by any good carpenter and smith, and each machine is wrought by a single person.

With these foot-machines any person may have his flax or hemp dressed under his own eye, by his own servants, and at times when otherwise they would be idle, in the dark afternoons of winter, when the lanthorns used by hecklers will prevent accidents by fire, and in the day-time when bad weather hinders working in the fields. Thus the dressing of flax and hemp becoming easy, the raising of these crops, of all the most profitable to the farmer, and to the country, will become more general ; many will have their flax or hemp dressed by their own servants, without expence ; and when others are hired to that work, the expence must be much less than by the hand method, as the machines are greatly more expeditious. The water-mills are not taken into this comparison, because their waste of the flax or hemp overbalances the profit of their greater dispatch.

The importance of this new machinery to Britain, Ireland, and the colonies, must appear very great, when the following particulars are considered.

The

The value of the flax and hemp raised in England yearly cannot be reckoned less than — 250,000 L.
 It appears from the custom-house accounts, that there was imported into England, from Christmas 1762, to Christmas 1763, 100,997 bushels of linseed. In the fens about Lincoln-wash, thirty towns and villages have yearly about 6000 acres of flax and hemp. There are likewise some thousand acres of these crops yearly in the marsh-lands on the borders of York and Lincoln-shires. The town of Snaith, in Yorkshire, has the greatest flax-market of any place in Britain.
 The value of the flax and hemp raised in Scotland yearly is calculated about — 190,000 L.
 There is imported into Scotland about 60,000 bushels of linseed yearly.
 The value of the flax and hemp raised in Ireland yearly may be reckoned about — 500,000 L.
 The linen manufacture there is about double that in Scotland, and mostly made of their own flax.
 Sum of these — 940,000 L.

The expence of breaking and scutching that 940,000 pounds worth of flax and hemp may be reckoned 150,000 pounds; one half of which, or 75,000 pounds per annum, must come in time to be saved by the use of the new machines; for the new scutcher does more than double the work of the old hand-scutch in the same time. The new brake is not so advantageous in that respect; yet the inventor thinks he errs on the safe side, when he states the new brake and scutcher both together, as doing only double work.

The colonies in America were till lately encouraged to raise flax and hemp, by a parliamentary bounty in Britain.

The great advantages of raising our own seed, flax, and hemp, instead of providing them from foreign countries, need not be here represented. What is at present imported appears from the custom-house accounts as follows: and it cannot be doubted but the aforesaid new machinery will be the means of increasing our own growth, and consequently decreasing the foreign importation.

The linseed imported into England is annually about 100,000 bushels, reckoned in value L.
 about — 40,000 L.
 Into Scotland, about 60,000 bushels — 25,000 L.
 Into Ireland, about 80,000 — 34,900 L.
 Flax and hemp into England, about — 700,000 L.
 Into Scotland, about — 120,000 L.
 Into Ireland, about — — — — —

Sum of these, exclusive of the blank for Ireland, 919,000 L.

And that there can be no want of market for an extension of our linen and hempen manufactures (which the new flax-machinery must greatly promote) appears evident from the extensive importation of these manufactures from foreign countries; for, according to the custom-house accounts, there is annually imported into England, from the continent of Europe,

Linen-yarn, of value about — 200,000 L.
 Linen-cloth, of value — 1,500,000 L.
 And thread, lace, sail-cloth, cordage, facking, &c. the amount of which must also be considerable.

Explanation of Plate XIV. representing the Foot-machines for breaking and beating Flax and Hemp.

Of the FOOT-BRAKE.

A The three under-brake teeth, or swords, seventeen inches long, three inches deep, one and a quarter inch thick at back or bottom, a quarter of an inch at B edge, the edges two and three quarters inches asunder at the end next the guide B, and two inches asunder at the other end.
 C The two upper teeth, about an inch shorter than the under teeth.
 D The brake-mallet, about thirty-three pounds English weight.
 E, e. A compound foot-treadle. E is eight feet four inches F between the fulcrums, raised at F eight inches above

the ground (or rather five inches higher than the stance of the workman). e is two feet four inches between the G fulcrums, and is raised at G eighteen inches above the ground: that is, fifteen inches higher than the stance of the workman.

H The sword or upright timber-rod which turns the wheel by the treadle-crank.

I The treadle-crank, of seven and a half inches radius.

K The fly-wheel, four and a half feet diameter, above sixty pounds English weight. As here represented it is beat or cast-iron, but it is also made of timber.

L Brass cods or bushes.

M, m The lifting crank, m is fixed firm upon the axle of the fly, while the crank M, about eight inches radius, plays freely round the axle. In position first, m begins to take round the crank (which by the lever R pulls up the mallet:) when it comes to position second, the mallet is again at liberty, and by its weight pulls up the crank (faster than the fixed pieces move) into position third.

N. B. The treadle-crank is advanced about one eighth part of the circle before the lifting crank.

a A small pulley which turns easily round on the end of the crank, and to which a rope is fixed.

O A piece of timber which prevents the rope from falling in upon the axle, but which should not rub against the rope in its coming down.

P Here the rope passes between two friction-rollers, which are so placed that the rope comes down there four inches, or half the radius of the lifting crank, or the side of a plummet-line crossing the center of the wheel; that is, to the side on which the crank turns when it pulls down the rope.

Q A pillar, which serves only to support the guard for the rope O, and the friction-rollers at P.

R The lever.

S The lever-pillar.

T Part of the mallet-frame.

U Two pillars which guide the brake-mallet.

V An iron spring which receives the leap of the mallet, and throws it the quicker down.

W The pillars which support the fly.

X, U The pillars which bear the brake-teeth and mallet.

Y Spur and cross, supports of the pillars.

Z The bottom frame-piece.

a A broad stool upon which the workman stands, three inches above the ground.

The brake-teeth are made of good beech or plane-tree, the brake-mallet of plane-tree, ash, elm, birch, or oak; the sword, or upright timber-rod between the treadle and the treadle-crank, of beech, plane-tree, or birch; and the lever of beech, ash, or oak. The fly-wheel, if timber, should be made of oak, ash, beech, elm, or plane-tree. All the other parts of timber worth mentioning may be made of fir.

Of the FOOT-BEATERS.

The before-mentioned brake may at any time be converted to a beater of flax and hemp, by removing the brake-teeth, and putting in their place flat boards. In the upper of these boards may be driven thirty-two nails, the head about three quarters of an inch long, and the point of the head about a quarter of an inch diameter; the points of the nail-heads may be placed one inch clear asunder, and in the order marked B, at equal distances, as in this way any of the nails may most easily be drawn out in repairing the mallet. An iron hoop about the mallet will prevent its bursting with the driving in of the nails.

For the sole purpose of beating flax and hemp, the narrow end of the mallet is placed towards the workman; and where there is much work in that way, the mallet and fly may be made heavier, and then two or more workmen can work together upon the foot-treadles, which may also be made equally long.

Plate XVII. fig. 1. represents the scutching machine, where b B G is the foot-board; D, D, scutchers; Q, the center of the iron wheel C, C, Q; S, the upright piece, or scutching slack; A the piece on which the hand rests in order to scutch the flax. The machine is put in motion by the nunch at M, which is moved by the foot-board.

We have been the more particular in our account of the various methods used in cultivating and dressing flax, be-

because it is an article, which, with proper encouragement may become of the utmost importance to these kingdoms; and therefore, we were persuaded that we could not do a more acceptable piece of service to the husbandman, than by giving the various methods at full length, though we are conscious that in doing this the reader will meet with some repetitions, which could not be avoided without curtailing the whole, and consequently rendering it less valuable.

FLAX-SEED for stall-fattening is recommended by Mr. Marshall, in his Rural Economy of Gloucester, vol. I. where he says, "that, next to hay, oil-cake made of linseed is the main article of stall-fattening. But the price of this article is at length become so exorbitant, that it no longer, I am afraid, leaves an adequate profit to the consumer. Some years back, I recollect, it was the idea of men of experience, that it could not be used profitably as an article of fattening for cattle, at a higher price than three pounds a ton. Now (1788) it is, in some places, more than twice that price. The lowest price, at the more distant mills, is, I am well informed, five pounds; at Berkeley mills, six pounds; at Evesham, six guineas; at Stratford, six pounds ten shillings a ton.

"This extravagant price of the cakes has induced some spirited individuals to try the linseed, itself, boiled to a jelly, and mixed with flour, bran or chaff; and, from the information I have had, with favourable success.

"This novel practice requires a few minutes reflection. From the present scarcity and dearth of cakes, it may be inferred that the demand is greater than the quantity in the markets. If, therefore, the seed can be profitably used; though with only a small increase of profit, and with this even on a contracted scale; the use of it may operate very beneficially; by lessening the demand, and thereby lowering the present exorbitant price, of the cakes.

"It is highly probable, however, that it may be used with much greater advantage than cakes at their present price. I have by me a sample of American feed, (nearly equal to the best Dutch seed I have seen), which may now be imported for 38 to 40s. a quarter, of eight Winchester bushels. Supposing the bushel to weigh 50lb. the price of this prime seed is not twelve pounds a ton. Ordinary seed might be had cheaper.

"It is farther probable that the superior kind of nutriment, which the cakes afford, proceeds from the unexpressed oil they contain, rather than from the husks of the seed of which they appear to consist. This being admitted, and seeing the excessive power which is used in extracting the oil, we may without risque conclude that a ton of seed contains more than twice (perhaps five times) the nourishment which remains in a ton of cakes.

"The principal objection to linseed jelly is the trouble of preparing it. In an instance in which it was used with success, the method of preparing was this. The proportion of water to seed was about seven to one. Having been steeped, in part of the water, eight and forty hours, previous to the boiling, the remainder was added, cold; and the whole boiled, gently, about two hours; keeping it in motion during the operation, to prevent its burning to the boiler; thus reducing the whole to a jelly like, or rather a gluey or ropy consistence. Cooled in tubs: given, in this instance, with a mixture of barley-meal, bran, and cut chaff; each bullock being allowed about two quarts of the jelly a day; or somewhat more than one quart of seed in four days: that is, in this case, about one sixteenth of the medium allowance of cake.

"This however is thrown out as a general idea; not drawn as an inference: the comparative effect of these two materials of fattening forms an important subject for the decision of experiment.

"Viewing the present subject in a partial light, it might be said that an unlimited and excessive use of a foreign article of fattening for cattle, might lessen the demand, and thereby lower the value of our own productions, applicable to the same purpose; to the injury of the landed interest. If, however, we consider that, by the use of foreign linseed, an influx of the first vegetable manure we are acquainted with would be diffused over the soils of this country; and that wheat may be exported at a price more than equivalent to the present price of linseed; the landed interest would seem to have no cause of alarm; while in a more general point of view, the importation of linseed from America might be a national good. I understand from intelligence of the first authority, that some of the finest provinces of that country, are in a great manner destitute

of marketable returns, for the produce and manufactures of this kingdom; and further, that linseed, which can there be grown in unlimited quantities, is at present a drug in the American markets."

FLAYL. See FLAIL.

FLEABANE, or *Fleawort*, the name of a perennial weed common in pastures, the stalk of which is round, bending, solid, and heavy. The leaves are oblong, sharp-pointed, wrinkled, downy, and embrace the stalk, on which they grow very thick without any regularity. The flowers are yellow, radiated, and inclosed in a flower-cup, made of narrow scales like bristles.

FLEAK, a gate set up in a gap.

FLEAWORT. See FLEABANE.

FLET-MILK, milk that has been skimmed, or had the cream taken off.

FLOATING of Meadows. See the article MEADOW.

FLOTE-FESCUE *grafs*, an excellent *grafs* for cattle, growing in watery places.

The *flote-fescue* affords excellent feed for horses. Mr. Stillingfleet, quoting a piece published in the Amæn. Acad. vol. III. entitled *Plantæ Esculentæ*; takes notice, that the author of it says, article 90, "That the seeds of this *grafs* are gathered yearly in Poland, and from thence carried into Germany, and sometimes into Sweden, and sold under the name of manna-seeds. These are much used at the tables of the great, on account of their nourishing quality and agreeable taste."

Our ingenious countryman, in his addition to this passage, has the following words: "Mr. Dean, a very sensible farmer at Ruscomb, in Berkshire, assured me, that a field, always lying under water, of about four acres, that was occupied by his father when he was a boy, was covered by a kind of *grafs* that maintained five farm-horses in good heart, from April to the end of harvest, without giving them any other kind of food, and that it yielded more than they could eat. He, at my desire, brought me some of the *grafs*, which proved to be the *flote-fescue*, with a mixture of the marsh-bent. Whether this last contributes much towards furnishing so good a pasture, I cannot say. They both throw out roots at the joints of the stalks, and therefore are likely to grow to a great length. In the index of dubious plants, at the end of Ray's Synopsis, there is mention made of a *grafs*, under the name of *gramen caninum supinum longissimum*, growing not far from Salisbury, twenty-four feet long. This must, by its length, be a *grafs* with a creeping stalk; and that there is a *grafs* in Wiltshire, growing in watery meadows, so valuable, that an acre of it lets for from ten to twelve pounds, I have been informed by several persons. These circumstances incline me to think it must be the *flote-fescue*; but whatever *grafs* it be, it certainly must deserve to be enquired after.

"There is a clamminess on the ear of the *flote-fescue* when the seeds are ripe, that tastes like honey, as I have often found; and for this reason, perhaps, they are called manna-seeds.

"Linnaeus Flor. Suec. article 95, says, that the bran of this *grafs* will cure horses troubled with bots, if kept from drinking for some hours." So far the very ingenious Mr. Stillingfleet.

From what has been said above, we may conclude, that the *flote-fescue* is one of the best *grasses* that we can cultivate for the use of our horses, and that more especially, as it appears to thrive best in wet, low meadows, where many other *grasses* would not grow.

There are at Clacton-Lodge, in the county of Essex, not far from Thorp, some low meadows, which are every year flooded for months together during the winter season: these meadows are covered with a *grafs* of a remarkable fattening quality; for when old cows have been turned into them, though they were ever so poor and low in flesh, they have in a very short space of time grown as remarkably fat; and when killed, their meat would appear as fine, and taste as well as that of any steer or ox; therefore it is reasonably to be supposed, that the *grafs* growing in these meadows is no other than that of the *flote-fescue*.

FLY, in turnips. See TURNIPS.

FLY, in sheep, a species of maggots very troublesome to that animal. The reader will find an infallible method to destroy these troublesome insects under the article SCAB in Sheep.

FOAL-TEETH. See the article *Age of a Horse*.

FODDER, hay, straw, haulm, &c. given to cattle.

In the foddering-yards of back-sheds, or other out-houses, to have several divisions, over and above what is constantly used, has great conveniences in it; one of which is, that in them you may dispose of a two-yearling cow, or another cow, at the time of bulling; not only to keep them from a bull, but from the other beasts also, that would be leaping such a cow, whereby they may hurt each other, &c. especially cows forward with calf will be apt to warp by leaping a bulling-cow.

The open winters make hay the dearest, if a hard frost and snow come at the fore-hand of them; for if once cattle come to fodder, they must be held to it, or they will receive great damage. In watery weather all the hay that can be given to cattle will not make them thrive, but in dry frosty weather they will thrive with their meat very well.

Mr. Lisle says, that he let his cows go at large from their foddering-yard, during the winter, and so continued till April, when they fed on some grass; and those that had calved, he foddered with hay: the consequence of which was, that by the middle of April his cows would not stand to eat any straw at all, but were, during the months of March and April, so weaned from straw, by baits of grass and hay, that they fell off from the straw quite, and grew much leaner, and worse in flesh than they had been, and apparently worse than the farmer's cows, which were, after the winter months, wholly pent up to their straw, and to the pond.

All sorts of cattle that chew the cud, as sheep, cows, &c. care not to graze after each other, nor to eat one another's leavings in the foddering-yards, but cattle that do not chew the cud will eat after those that do, and *vice versa*.

Pliny tells us, where hay was scarce, it was usual to feed their cattle with chaff and barley-straw. Of chaff, says he, that is the best sort, which is the thinnest and smallest, and nearest to dust; the best therefore is from miller, the next from barley, and the worst from wheat, except it be for hard-labouring beasts.

On sound experience I am convinced, says Mr. Lisle, that in our hilly-country we ought not to have any dependence on sending our cattle out of the foddering-yard to grass before the middle of May, and therefore we ought to be provided with winter-fodder for cows accordingly.

At the beginning of winter, suppose the latter end of October, and a great part of November, while cattle still continue out in the field at grass, it is very necessary to fodder them early in the morning, while the hoar-frost hangs on the grass, which they will not eat kindly off till the sun has warmed it.

The straddling racks are best for foddering, if made strong enough, that is, so as not to be over-turned; for these racks may be lifted up as the dung mixen rises, which those fixed in the ground cannot be.

It is a practice in many places, to tie their cows up to a rack to fodder; but if a person would rightly consider the places where it is done, we should find it only used where the fodder is good, being either hay, or very good straw; but in the hill-country of Hampshire, where the cattle have straw fodder only, and that not so good as the straw in the valleys, the custom is to fodder their cows in racks, or cribs, in the open yard, which they think better than tying their cattle up to racks in houses; for though in cold and rainy weather the houses may keep their loins dry, yet in countries where the fodder is coarse, especially after wet and backward harvests, when the spirit of the straw is washed out by the rain, the giving cattle straw from racks, from whence they cannot pick and choose, as from cribs they may, is judged to tend to the impoverishing the cattle, whereas in cribs they can pick the sweet from the coarse.

There is a very remarkable difference in cattle eating their fodder, when fresh threshed, and when it has been threshed two or three days, especially if the straw be but indifferent fodder. *Lisle's Husbandry, vol. I. page 392.*

FOGGE, long grass remaining in pastures till winter.

FOISSEN, the natural juice or moisture of the grass or other herbs.

FOLD, the moveable inclosure wherein sheep are confined during the night.

It appears that the sheep-folds of the eastern nations were not such as ours, but houses erected for that purpose.

Mr. Garret, who had lived four years in Spain, says the ingenious Mr. Lisle, assures me, that in those parts where he was, they fold their sheep as we do ours, only their fold is made netwise with strong cords, and about six feet high, with the bottom flaked down to the ground, and two cur-dogs of a breed between a mastiff and a greyhound, lie within the fold to guard the sheep from the wolf.

"In favour rather of keeping a wether-flock than an ewe-flock on the hill-country, besides other conveniences, you may have the benefit of the fold for barley at the principal time when it does most good, viz. on the fallows between the latter end of February and the middle of April, when the ewes cannot be folded.

"The limitation of an ewe-flock for folding and keeping on throughout the winter, or be it a wether-flock, ought to depend on these rules; First, Not keep more at winter than you can winter, either by meads, or sowed grasses and hay. Secondly, Not to be satisfied that you can provide hay for them by sowed grasses, as broad clover, &c. in case such lands as are fitted to carry such grasses, lie at a distance for mowing, whereby you must maintain them with dung, where, by reason of carriage, it will be chargeable, unless your fold can maintain more ground than your out-lying lands to your farm, which, in the hill country, is not likely: and to carry but seven or eight pots of dung in a day, by reason of the distance, and mowing, is not reaping a profit, but bare exchanging: but if you have much land round about, and near your house, whereto you can carry thirty or forty load of dung a day, and which will bear broad clover hay, then you may increase your flock proportionably.

"As to fattening your ewes and lambs out of your flock, if you have lands disposed for fattening, you ought to consider, if you break your flock by drawing out ewes with their lambs for that purpose, what flock you will have left to fold on your wheat fallows, and how far your wheat land stand in need of a fold; for if you leave yourself not sufficient, it will be indiscretion to weaken your fold; besides, it will hurt your breed; for you will draw off many forward lambs, which might, perhaps, have carried on the breed otherwise, and when a hill country farmer is settled in a flock, it is not good to be buying yearly, to keep up his complement, on account of many dangers which may from thence ensue; it is better, therefore, in such case to buy ewes with their forward lambs to put into your fattening grounds; but in case you sow wheat-land good enough without the fold, or have another way of manuring it, by liming, &c. then it may be very well to fat off certain numbers of your flock.

"Though, says a very good farmer of my acquaintance, I have but a mean opinion of winter folding, or to fold on barley sown, and may in time fallow on grass-ground instead of barley-land, yet I would fold on barley-land fallowed or stirred, from the time my lambs were stiff enough after lambing to go on such fallows; for, says he, the benefit of an acre so folded, is three times as good as one winter-folded for barley.

"Farmer Glyde, of the Isle of Wight, with whom I was talking of husbandry affairs, told me, there was one thing he believed I knew not of, which he would tell me; he would, he said, advise me to fold my ewes and lambs on the barley-land in the spring, and divide my flocks in folding; for, said he, two hundred ewes and their lambs will do as much, if not more good, by folding on an acre of land, as four hundred wethers: I have, said he, folded a part of the same land at the same time two hundred ewes and their lambs, and in another fold of equal dimension five hundred wethers; and I have always found, that the folding of the ewes did me the best service, and brought me the best corn.

"My shepherd is of opinion, that ewes ought not to be folded on the barley fallows, or any other fallows in lambing-time, but wethers only; for the lambs, being wet, when lambed, would be dirtied with the fallows, and the ewes would presently forsake them; therefore the ewes ought in lambing time to be folded in the meadows, where it is clean, and the folds removed as often as the cold

cold wind should change from corner to corner. And afterwards, he said, they ought to fold wethers on the barley till a fortnight after May, but the ewes never after Candlemas.

"It is plain, that the early folding an ewe-flock, and lambs in April, on wheat-fallows, pinches the lambs, and so does folding them at that time on the barley-grounds, both which are too cold for them, especially on our hill country; care ought therefore to be taken, that those lands do not of necessity want folding on in those months, but that they may be otherwise provided for, and that during that time the ewe-fold may be on grass-grounds, or lay-grounds designed for fallows.

"We must be more cautious in April and May of folding an ewe-fold on the barley land, they being wettest, than of folding them on the wheat sown in August or September; because the lambs in April and May make the ewes rise often and move, whereby the ground becomes much more trodden at that time of the year by the ewe-fold, than it would be by a wether-fold, or an hog-fold, as may apparently be seen, if the folds be divided.

"Telling Mr. Gerrish the grazier, and farmer Isles, how dear Mr. Eyres our minister fold fat lambs to the number of fifteen, May eighteenth, viz. for ten shillings and six-pence each, and that they had been folded all along to the very day he sold them: they replied, that folding the lambs did very little hurt to them with respect to their fat, provided they were drove pretty late to fold, and let out early in the morning.

"Walking with Mr. Raymond into his arable common fields, October twenty-fifth (anno 1728) we met his shepherd pitching the fold on the new sowed wheat. I asked him, whether he did not find that pitching the fold on the wheat at this time of the year, and a fortnight later, turned to a much better account than folding for the barley crop for the year following. Mr. Raymond and his shepherd readily replied, undoubtedly it turned to the best account to fold after this time on wheat. I said, for my part, I had observed the fold carried on the land, designed for barley so early in the winter had little effect, its strength being spent and washed away by spring, so that it will make but little shew in the crop of barley next summer, and that therefore I chose to preserve four, five, or six acres of wheat-fallow that lies warm, and will bear sowing late, to carry my fold over to the latter end of October, rather than finish my wheat fold by the end of September, and then carry it on my barley; for though the latter part of October might, in our cold country, be too late to sow wheat, yet it was better than to be so soon folding barley, which would be no better for it. To which they replied, I was much in the right. And as I have before observed how insignificant the folds is in the winter, especially in hard frosts, I imparted it to Mr. Raymond, who concurred with me, and said, he had folded on arable land in snow, and found not the least benefit: whereupon he resolved in such cases to fold on meadow and pasture, in mighty expectations of grass: but it made no return; wherefore in snows he now lets sheep ramble.

"Whereas I have said, that in cold clay-ground, and in a cold hill country, a winter-fold does little good; yet I have by experience found the contrary in such parts of the hill country, where the land is dry and light, and that it does great service to the barley-crop. This difference may be reconciled thus, i. e. where the land, though called hill country land, does not lie very high, for the height much tends to the chilling of the ground. Again, the explanatory reason of this difference, though hardly accountable for, yet seems to me chiefly to lie in the chilling quality of the ground which at first receives the dung and urine, and that deadens the ferment; whereas in warmer ground its progression toward that end is supported by a sufficient benign warmth, since in both sorts of earth, the urine does undeniably sink into the earth, and mix with it.

"My ground being cold and feeding, I should in the spring of the year, when I come either to pitch my fold on the barley fallows, or on the sown barley, set it very wide, in order to avoid the usual inconveniences of penning at that time, viz. the rankness and lodging of the barley, and the conveniences, thinness, and coarseness.

"It was the tenth of October (anno 1720) when my fold was going to be set on the wheat-fallows of a field, which was heavy land, and the fallows, where the fold

was to go, were to be ploughed up the next day; I was afraid the land would be too wet to fold on after the wheat was sown, and spoke to the shepherd about it. He said, he believed I might be in the right, especially since the rams have been some days put to ramming the ewes, because the rams would keep moving and stirring the ewes all night in the fold, whereby the ground would be battered and trod, and so squatted, that the wheat might not get through.

"That the Greeks did pen up their sheep, that they might piss through hurdles, as in Herefordshire, you may see in Palladius's calendar, November, to avoid dirtying and damaging their fleeces.

"Farmer Miles, whom I have often mentioned with approbation, advised me, if I would turn arable into meadow, and lay it up to grass, to fling straw upon it that is less than half rotten, and then fold upon it the same night, and it will bring the ground on very fast.

"Pursuant to what has been before said, that folding in winter for barley is not profitable, because, by waiting for the fold's running over the land, we lose the principal season for fallowing; yet however it may be proper to fold till Christmas, and then go on the wheat-lay; because we can lose no fallowing season by that; we cannot well have finished our fallowing any year before Christmas.

"I find by Mr. Antill and Mr. Clerk, and others, that in Leicestershire they have no winter-folding for barley; they leave off by Michaelmas at farthest, and sometimes cannot fold again till May; the reason is, their lands are so wet they would be always in a poach, and the coldness of the lands would kill the sheep: to help which defect, they muck their barley-lands, and from thence begin their husbandry, and sow wheat the year after, often under furrow, on their barley-stubble, for they say, if they should dung their wheat-ground it would rot their wheat, and they sow peas and beans after the wheat, and then lay the ground to summer-fallow again, to be mucked in May for barley, or to fold for wheat; so that they carry out their dung before it is half rotten, or the seeds of the weeds killed: but in their inclosures they sow four crops of corn all on one earth, without dung, for the most part beginning with oats, and laying down to grass with wheat.

"I am told that in Dorsetshire the aim of the farmers is, to fold on their sheep-leaves in the middle of July, and so till Michaelmas, that in the winter there may be a good head of grass for the milch-ewes.

"It seems to be inconvenient to grasp at so large a wheat or barley-crop, as hardly to be able to compass it without folding late on the wheat after it is sowed, or on the barley land after it is sowed; for by being under the above necessity, in order to compass what one has engrossed, one may often be obliged to fold unseasonably on each sort of corn, nor will the fold in that case make good the damage done to the flock by the lateness of the season; and an ewe-fold is often damaged by folding on the cold land at the latter end of October; whereas it is better to come early with your fold off of the wheat-lands on to the barley ley-grounds, and from the sowed barley on to the wheat-fallows; for thereby you will fold the same quantity of ground of the respective grains without the respective inconveniences.

"Between washing and shearing-time sheep ought not to be folded, because of dirtying their wool, nor from the cutting of the lambs till a fortnight after, nor in sheep-leaves or arable in wet weather, for it will tread the grass into dung.

"A servant of mine, a man of very good understanding, tells me, he has been many years a shepherd, but could never observe that the fold ever did any good in frosty weather: particularly he remembers a very sharp frosty winter, in which a whole flock used daily to gather to a hay-reck, in a ground where they were foddered, yet he could not observe there was any better corn there than elsewhere. I asked him the reason of it; he said, the frost wasted and preyed on the dung; and I rather approve this observation of his, because of the great prejudice strong beer and spirits receive by being frozen, even so as to become mere *caput mortuum*.

"If frost has the same effect on dung, by impoverishing it, that it is said to have on the sheep-fold, and on strong beer: quere, whether it be proper or not, to leave horse or cow-dung spread on land without ploughing it in?

"Mr.

" Mr. Raymond is also of opinion, that the winter frosts do very much deaden the folding of the sheep, and rob it of its virtue.

" Farmer Elton said, the method he best approved of in folding, was always to fold that land first that was first designed to be ploughed, such as white or whitish land, they not being apt to bear weeds, nor will the fold be apt to cause weeds to come, and such land he would sow first, viz. at St. James's-tide. I said, I should think, though such land should be sowed ever so wet, yet, if the month of August should prove dry and scorching, it would burn, and suffer by such early sowing. He replied, if sowed wet, yet so as it came up, he never knew the drough to hurt it.

" It was a very dry season from the first of March to the sixth of May (anno 1721) during which time I set my fold on my barley. Several of the farmers in my neighbourhood said, it would be apt to do the barley more harm than good, for the sheep would scratch up the seed; whereas, if rain had come, so that the ground had not been in a dust, their scratching would have done no harm. But I rolled before I set my fold, and so I presume the ground was so fast as to receive the less damage, it being also stoney, and therefore the sheep could not scratch it so much as otherwise perhaps they might have done: the event was, the fold did no harm, but good.

" Mr. Gilbert of Maddington was telling me, the way of husbandry about him, near Salisbury, was, to fold on their wheat after it was sowed till St. Luke's-tide, which is in the middle of October; then to draw off their flock for a month to fold their sheep-leaves, and then on the barley-fallows. I asked some North-Wiltshire farmers, if about them they ever folded on the wheat-land after it was sowed; they said no, they never knew it to be done in any parts thereabouts, yet folding after the corn was sown did it more good than before; but the reason why they did not do it about Holt, &c. they believed was, because they were forced to lay up the wheat-lands in high ridges by reason of the deepness of the earth, and its wetness, and the sheep if folded on such land, would do nothing but lie between the furrows, which would do the land but little service: besides, they said, in the hill-country the land was rather of the lightest, and that the treading of the sheep, after it was sowed, pressed it closer than it was before, and so did it service.

" Mr. Raymond assured me, that sheep folded on sandy lands would thereby be sensibly more impoverished than those folded on clay lands, and this said he, the shepherds agree to, who live where there are such different sorts of land. The reason seems to be, because the sandy lands draw forth and drink up the moisture of the sheep to fill up which emptiness of the outward vessels, a fresh juice must succeed, and so on; or else that the sandy lands being hot, make the sheep perspire more than clay-lands do, whereas the cold clay rather repels perspiration.

" If sandy or light ground, as has been before hinted, draws the fat and moisture of the sheep-fold off, so as to impoverish a flock more than if they had been folded on cold clay-lands, it must be allowed, on the other hand, that light ground may be better enriched by a fold than heavy land, because the light ground imbibes more of the moisture and fat of the flock; and this gives some account why it is said, poor lands often pay better for their folding than strong lands: for the same reason winter-folding, when the ground is wet and cold, holds no proportion to summer-folding.

" Discoursing with farmer Biggs on husbandry, he said, he folded on the fallows all winter long, though never so wet; yet, said he again, sometimes the fold does harm; let be it never so wet, said he, early in the year, folding on the fallows does no harm; for, in the first, there is heat enough in the ground at the first hand of the year to keep off the chill, and then the ground is not so settled, but that the rain soon runs through it; but at the latter end of the year the ground is settled; then treading it with the fold in wet weather makes it hold water, by which it may be chilled, and kneads the very wet into it, whereby there will be the less corn.

" Before I came from Crux-Easton in February (anno 1698) in order to go into the Isle of Wight, I had a discourse with an old experienced shepherd about folding the flock on fallows: he said, as to wheat, it was excellently good, but they rarely folded on barley-land after it was sowed, for if it was a whitish land, and a hot summer came, it would be burnt up: besides, the sheep would be scraping at

that time of the year on barley-land, and would take the corn out of the ground; but the wheat, said he, lays too deep for them to do so. But when I came into the Isle of Wight, farmer Collins was of a different opinion, and said, he had alway folded with good success on hot, dry, sandy ground after it was sown with barley, and was earnest with me to try it; for said he, you will quickly see the benefit, and though the sheep should scrape, you will find the barley come thickest there. There is land, however, about Hufborne and Stoke in Hants, that will burn by folding on in the spring, and get more harm than good, if hot weather come, it being a hungry sharp gravel.

" As it seems to me, the double folding on the early wheat-fallows, to be sown on one earth, cannot occasion the roots of the grass ploughed-in to shoot up afresh, but rather prevents it, by treading the earth down into a hard plaister, so that they cannot rise; it is true, it may bring up afresh new grass, which having weak roots, will easily be torn up by the draggs.

" Columella, speaking of feeding sheep, says, there is no sort of land or food, but what (by the continual use of that only) sheep will be tired of, unless you give them some salt now and then to lick, from whence they may procure a new appetite to their meat and water. All the summer time, during the hot season, they must be let out to feed as early as may be, while the dew is on the grass; and when the sun is about four hours high, they must be led to water and under the shade, and again to feed towards sun-set. In the dog-days the flock should be so led as to feed with their heads towards the west in the forenoon, and towards the east in the afternoon; for it is of great consequence, says he, that the sheep's heads should be turned from the sun, which would be hurtful to them. And Varro gives the same directions, because, says he, the sheeps-heads are extremely soft. Perhaps this may be the chief reason of the rams and ewes in companies turning face to face, in hot sun-shiney days. During the winter, and early in the spring, they should be kept in their fold, till the sun has melted the hoar-frost from the grass, which would occasion rheums in their heads, and would also scour them: for this reason in cold wet seasons of the year they should be watered but once a day. They let their ewes, as Varro assures us, go out to feed with the rest of the flock, but kept back the lambs, which were suckled by the ewes at their return, and then again separated from them. They also tethered their lambs ten days old, lest they should dislocate or hurt their tender limbs by playing together." *Lisle's Husbandry, vol. II. page 178.*

Mr. Young, in his Annals of Agriculture, says, in respect to folding, " Mr. Bakewell's opinion is singular. He is decidedly an enemy to the practice, (except when flocks go on large, open commons in the day time, and are considered as dung-carriers to the arable land) and thinks that the advantages, supposed to be derived from it, are visionary; being, in fact, no more than robbing a large part of a farm to enrich a small one. That large flocks, even any number kept together above 100, are a barbarous practice; for, in such flocks, the strongest will beat the rest from their food; instead of which, the weakest sheep should have the best food; and, if folding is necessary on farms that have no commons annexed to them, why not have different small folds on different parts of the farm, and sort those of different kinds, or ages and strength, and thereby save the trouble of driving from one part of the farm to another? For, had not the animal, after it has filled its belly, better lie down to sleep than travel to create an appetite? And he is of opinion, from all the observations he has made in various parts of the kingdom, where folding is and is not practised, that experience strongly confirms the idea. Mr. Culley is of the same opinion. I must declare my own ideas to be far as the poles asunder. I consider folding to be a kind of summer farm-yard, that collects—what, collected, is manure; but, scattered, is little or none."

FOLE-FOOT, the same with colts-foot. See COLT'S-FOOT.

FOOD, a general name for whatever aliments are taken into the body to nourish it.

Food of plants, the particles they extract from the soil, air, &c. in order to their nourishment.

Philosophical enquiries into the principles of vegetation, and in the manner in which it is performed, are an object well worthy the attention of gentlemen whose situation allows them to pursue that truly useful and entertaining study. But as the industrious husbandman, for whose benefit this work is chiefly intended, as a compendium of the best practice

tice in agriculture, founded on the result of experience, cannot afford time for matters of speculation; nor would they, in point of prudence, consist with his necessary occupations, even if his education fitted him for such researches; it may be sufficient for him to form a general, but just, idea of the means by which plants are most successfully raised. A proper notion of this will help to guide him in the management of his lands, and shew him in what state the earth should be, to enable the plants which he cultivates most easily and readily to find their necessary food. This general knowledge of the basis of agriculture is even requisite in every one who would be satisfied of the reasonableness of his methods of proceeding.

Whether any one active principle does universally nourish all plants, or whether some particular salts or juices feed one plant, and others another, is a question, that has been warmly debated by philosophers.

The ancients generally entitled the earth to the production of the animals, vegetables, and other bodies, upon and about it; but several of the moderns, and among them some of very great name, both here and abroad, have declared in favour of water, as the efficient cause of vegetation. Lord Bacon was of opinion, that, "for the nourishment of vegetables, water is almost all in all: and that the earth doth but keep the plant upright, and save it from over heat and over cold." Others carry this hypothesis still farther, asserting water to be the only principle or ingredient of all natural things. They suppose that, by I know not what process of nature, water is transmuted into stones, into plants, and, in short, all other substances whatever. Van Helmont, and his followers, to whose opinion even the illustrious Mr. Boyle has shewn a strong propensity, are very positive in this, and alledge, as proofs, the considerable growth of mint, and several other plants, in water, and his well-known experiment on a willow-tree. Van Helmont planted this tree, which weighed five pounds, in two hundred pounds of earth dried in an oven, and watered it with rain, or distilled water, after carefully covering the case in which it stood with a perforated tin cover to prevent the admittance of any other earth. Five years after, weighing the tree, with all the leaves it had produced in that time, he found its weight to amount to one hundred and sixty-nine pounds three ounces; while the weight of the earth was only diminished about two ounces.

Mr. Evelyn thought, with the learned Dr. Sharrock, whom he quotes, that water is, of its own constitution alone, a soil to vegetables, not only as the most genuine vehicle of the riches which it imparts to plants, through the several strainers, and by means of which all change and melioration is effected; but because it is, of all other substances, best disposed for ingress, to insinuate into, and fertilize the earth; which is the reason why floated grounds are so remarkably fertile after the flood has subsided. "It is, says he, the nearest of kin to the vegetable race; for to assert, with any confidence, what part of the mere earth passes into their composition, or whether the earth serves only for stability, or as a womb and receptacle to their seeds, I shall not undertake to discuss; though I do not yet conceive the earth to be altogether so dull and inactive, as to afford no other aid to the generation of what she bears; the diversity of soils being infinitely various, and the difference of invisible infusions far beyond our arithmetic. But neither do I here by any means exclude the air, nor deny its perpetual commerce and benign influences, charged as it comes with those pregnant and subtle particles, which prevailing and insinuating into the earth's more steady and less volatile salts, that intestine fermentation is begun and promoted, which gives life, growth, and motion, to all that she produces. Dr. Mayow has proved, that the most exhausted and worn-out mould, is repaired by a bare exposure to the air alone, without which it produces nothing. Nor can plants, totally excluded from the air, live, or so much as erect themselves to any thriving purpose, as being deprived of that breath and vital balm, which no less contributes to their growth and nourishment than does the earth itself, with all our assistance. Besides, we find that the air is near of kin and affinity to water, and indeed seems as it were but a thinner water; for how else are vines, and other trees of prodigious growth, maintained among barren rocks, and thirsty pumices where rains but seldom fall, if not from the benign influences of the air?"

To this aerial food and moisture it is that most of the sedum kind owe their growth. Succulent groundsel, and the fragrant wall-flower, draw their nourishment from the same source. An ash now growing out of a wall of the abbey-

church at St. Alban's, affords a remarkable instance how much even trees are nourished by the air.

As all kinds of water, as well as air, contain many other substances besides the pure elements of water and air, it is difficult to ascertain whether these extraneous substances, or some of them, are not the food of plants. Dr. Woodward's experiments, as related in the Philosophical Transactions, seem to confirm the opinion that they are; for he observes, that a great part of what he calls terrestrial matter, mixed with the water in his experiments, ascended up into the plant, as well as the water; and the plants were more or less nourished in proportion as the water in which they stood contained a greater or smaller quantity of that matter. With regard to Van Helmont's tree, and the growth of plants in water, he very justly observes, that nothing like what the advocates for water would infer from thence, can possibly be concluded from any such experiments, unless the water used in them be absolutely pure, homogeneous, and not charged with any sort of terrestrial mixture, to which the plant may owe its growth and increase: for that all water, even the clearest and most transparent, does abound with such matter, will appear to any one who shall put some of the very purest into a clean glass phial, and stop it with the greatest care. Though perfectly transparent at first, it will grow cloudy, if suffered to stand some time without being stirred, and at length deposit an opaque sediment. Filtering and distilling will intercept some of the earthy particles with which it is naturally charged, but neither of these operations, nor any other that we know of, though ever so often repeated, will free it entirely from all extraneous matter, some of which will always remain in it, very fine and light, fit to attend every motion of the water, whose extreme tenuity, and exactly spherical globules, enable it to preclude smaller ducts than even imagination can conceive. We hardly know any fluid in all nature, except fire, whose constituent parts are so extremely subtle as those of water. They will pass through pores and interstices, impervious to air, or any other fluid. This enables them to enter the finest tubes and vessels of plants, and to introduce the nutritive matter lodged in the earth, conveying it to all parts of them; whilst each, by means of organs it is endowed with for the purpose, intercepts and assumes into itself such particles as are suitable to its own nature: letting the rest pass on through the common ducts.

The judicious Mr. Worlidge, uninfluenced by the new and prevailing mode of thinking in his time, according to which all vegetables were supposed to be fed by water only, declares positively, that he cannot but explode this opinion as destitute of foundation; for that, although several plants set in water only, do emit fibrous roots, and flourish therein for a time; yet, at best, this nourishment is but weak, because water does not contain a sufficient quantity of the true nutritive particles as the willow, poplar, and other aquatic plants raised therein, demonstrate, and as is still farther evident from their better thriving if the water be often changed. "Experiments, says he, have been made of gourds and cucumbers, planted in baked earth, and watered with water only; and after they have grown to such a bulk as the experimenter thinks proper, they are weighed, and also the earth, which last is probably but little diminished, or perhaps not at all; from whence they conclude, that the substance of those vegetables proceeded from the water. Thus have men made experiments speak as they would have them, to favour the new opinions they would impose on the credulous.

Spring and rain-water contain pretty near an equal charge of vegetable matter; river-water more than either of them. Nor can any doubt be made, but that the water which falls in rain at some times, is more charged with particles fit for the vegetation of plants, than that which falls at others. A more powerful degree of heat must draw up a larger quantity of that matter, with the humid vapours which form rain, than a more feeble warmth possibly can. The water of one spring may also flow with a higher charge of this matter than that of another: this depending partly upon the briskness of ebullition of the water, and partly upon the quantity of that matter latent in the earth, through which the fluid passes, and the greater or less laxity of that earth. For the same reason, the water of one river may abound with it more than that of another; and the same river, when much agitated, may bear up more of it than when it moves with less rapidity.

Though water be not itself the food of plants, it is an absolutely necessary agent, by which the matter proper for their

nourishment, which remains inactive till it be diluted by, and incorporated with this fluid, is conveyed to them, and introduced and distributed into their several parts, both from the earth and the air. But still it is not capable of performing even this office, without the concurrent assistance of heat, which gives it the necessary action, exalts and digests the nutritive juices, dilates the pores of the plant, and raises the sap into the stem, branches and fruit, where the sun perfects the work, by ripening it.

The necessity of heat in vegetation is apparent from our fields and forests, our gardens and our orchards. We see, that in autumn, as the power of the sun decreases, so its effects on plants diminish, and their vegetation slackens by degrees. Its failure is first discernable in trees, which, being raised high above the earth, require the most heat to elevate the water, charged with their nourishment, to their tops and extremities; so that for want of fresh support and nutriment, they shed their leaves, unless secured by a firm and hardy constitution, like that of our ever-greens. Next, the shrubs part with theirs; and the herbs and lower tribes; the heat being, at length, not sufficient to supply even these, though so near the earth, the fund of their nourishment. As the heat returns with the ensuing spring, they all recruit again, and are furnished with fresh supplies of verdure: First, those which are lowest and nearest the earth, because they require the least degree of heat to raise into them the water with its nutritive charge; next, the shrubs and higher vegetables, in their turns; and, lastly, the trees. As the heat increases, it grows too powerful, and hurries the sap with too great rapidity through the finer and more tender plants. These, therefore, go off and decay; and others, which are more hardy and vigorous, and require a greater degree of warmth, succeed in their order.

Mr. Tull is the only person who makes earth the food of plants. The experience of all ages contradicts this opinion; for the necessity of inducing something into poor soils, to enable them to produce crops, is universally acknowledged; whereas, if earth alone was the food of plants, it would in all cases produce the same effect.

As to the grand question, whether plants of different kinds are nourished by one universal food, or whether each particular species imbibes only its peculiar aliment; the supporters of this last opinion, among whom are the great lord Verulam and Dr. Woodward, say, it is not possible to conceive that one uniform homogenous matter should constitute bodies so unlike in all respects as the various tribes of vegetables; nay, even as the different parts of the same plant. But a moment's reflection will shew, that the latter part of this objection confutes the former: for if the plant has the power of altering the original juices taken in by the roots into so many various forms as experience proves it has, each plant may be indued with the faculty of assimilating to itself the juices it meets with in the earth; as we find the same food not only nourish different animals, but produce in each its peculiar character.

We have ocular demonstration, that the willow and alder thrive best on a moist soil, and that the elm, pine, fir, and cypress, prefer a drier earth. Yet these, and many more of the widest difference, are sometimes seen to draw their whole sustenance, bulk, and ornaments, whether annual or perennial, from the juices they find in the same piece of ground, and from the ambient air and dews; though our strictest diligence cannot distinguish the particular aliments which approach their several roots. Changing the earth about the roots of these, or any other trees, whose bark, sap, fruit, and seed, are of very different kinds and qualities, will only make each tree prosper the better. "Hence, says Dr. Beal, we may justly suspect, that the very contextures of their bodies, from the first spirting of their seed, and as they are formed gradually from the invisible principles of spirit and vigour of their seeds, however small and imperceptible, are the natural alembics, where the common rain-water and air are digested into very much differing leaves, fruit, seed, resins, gums, &c. perhaps as the cow's-belly converts the common juices of all sorts of grass into milk, or as the bee collects honey and wax from all sorts of flowers."

The same soil that has once been proper for the production of some sorts of vegetables (continue those who think that each particular species of plants has its particular food) does not always continue to be so; but in time loses its property. If wheat, for example, be sown upon land proper for that grain, the first crop will succeed very well, and perhaps the second, or as long as the ground is in heart; but in

a few years it will produce no more, if sown with that corn. Some other it may, as barley, rye, or buck-wheat.

That this is owing to an improper culture of the land, more than to any defect in the soil itself, will evidently appear to those who shall candidly weigh the principles of the New Husbandry, when that subject comes to be treated of.

Mr. Du Hamel makes no doubt, but that the particles which plants appropriate to themselves, take different forms in each plant, and even in the several parts of the same plant; but, as he justly observes, it does not at all follow from thence, that they were not originally the same. What would induce one to think them the same, is, that plants of different kinds rob one another of the nourishment which is in the earth: for, if a lettuce, for example, drew from the earth a food different from that of endive, a lettuce planted among endive would not only thrive better than if planted among other lettuce, but as well as if no other plant was near it. But we know, by experience, that this lettuce would grow very poorly, and consequently that plants, though of different species, do hurt and rob one another. If each plant drew from the earth only the particular juices proper for itself, poppies, thistles, &c. which kill wheat, would not in that case do it any hurt, farther than by shading it with their stalks. But that the injury they do the corn is chiefly occasioned by their roots, which consume the necessary nutritive juices, is evident from this, that if dry branches were set in such numbers as to make even a greater shade than those weeds, they would not equally prejudice the growth of the wheat.

After some other arguments of equal force, Mr. Du Hamel concludes, that plants of different species feed on the same, or nearly the same substances; that there is no plant which does not rob those that are within its reach of some part of their food; and that the soil which once is good for any one kind of plant, will always be able to supply it with food, provided it be properly cultivated.

To prove that the same juice takes different qualities in the vessels of the same plant, he instances an experiment which he made, by grafting a young lemon, of the size of a pea, by the stalk, upon a branch of an orange-tree. It grew there, ripened, and retained its quality of lemon without partaking in any shape of that of the orange. The juices of the orange-tree must therefore have changed their nature at once, on their passing into the lemon.

It is an old opinion, generally received by the ancients under the name of occult qualities, or sympathy and antipathy, that some plants delight in being near each other, while others will not live together. Several of the moderns have likewise embraced this sentiment, and urged in support of it, the fig-tree and rue, garlick and the rose, which, say they, agree remarkably well together, because the juices suited to the one are avoided by the other. Lavender, laurel, thyme, marjoram, and other aromatic plants, cannot, on the contrary, according to them, flourish together, because they feed on similar juices, of which they rob one another. Mr. Evelyn seems to be nearer the truth, when, speaking of this subject, he assigns as a reason why some plants will not thrive near others, certain effluvia or streams emitted by the one, which may be noxious to the other. Plants will not thrive under the walnut-tree, the oak, and others of the same kind, because their numerous and wide-extended roots exhaust the earth around them, and the drippings from their leaves are impregnated with an acrid matter, which is an enemy to vegetation.

Though there are evident instances of an election of food in some plants of very different kinds, such as the aquatic race, and those which delight in a dry situation; yet, so far as relates to the farmer, they may be said to be nourished with one and the same substance; but at the same time it is necessary, that both the earth and that substance be fitted for receiving and nourishing them: for be the earth ever so good, rich, and proper for the production of vegetables, little will come of it, unless its parts have that just degree of strength, or cohesion, which shall give stability to the plant, and at the same time afford an easy admittance to the fibres of its roots, to spread and extend themselves in search of that food.

The question, what is the food for plants? is of very difficult solution, as appears by the different opinions of those who have attempted to solve it. One thing is observable, that those who have endeavoured to answer this question, suppose, that the vegetable food is some one kind of matter, water, air, salt, or earth, but they do not seem to mean, that plants feed upon either of these alone, exclusively

ly of the other principles, for those who contend for water, for example, being that food, acknowledge, that the other elements are also necessary, and concur with water to feed a plant : they acknowledge that air is necessary, so necessary that vegetation cannot go on without air ; and the same may be said of the rest. Their meaning therefore appears to be, that the principle which they adopt, and suppose to be the food of plants, is so principally.

In the same manner, Mr. Tull was of opinion, that earth was that food ; not however excluding the other elements, but that earth was chiefly or principally that food : for so he explains himself, page 14 of his Husbandry, where he says, " and earth is so surely the food of all plants, that *with the proper share of the other elements*, which each species of plants requires, I do not find but that any common earth will nourish any plant." Now which of these opinions is right, or whether any of them is so, is very hard to determine. Mr. Tull's definition of the vegetable food, is in p. 10, " By food is meant that matter, which being added and united to the first *flamina* of plants, or *plantule*, which were made in little at the creation, gives them, or rather is, their increase. By this definition, earth seems to have a better claim of being the food of plants, than either of the other elements ; as earth is of a more solid and permanent nature, than air, water, or salt."

But whatever this food is, it does not appear that the researches of the curious concerning it, have hitherto been of much benefit to husbandmen, or to the improvement of agriculture. The discovery they aim at is chiefly theoretical.

But though it remains unknown what is the food of plants, there is another point of great importance discovered, namely whence that food is derived. It is found that the earth is enriched from the air or atmosphere. That though it should be ever so much impoverished, and exhausted by a repetition of robbing crops, it may be restored to its former fertility, and enriched to a high degree by good tillage, and exposure to the air, by which it is again replenished with those fertilizing particles, whereof it was before exhausted. This is a plain easy theory, that is intelligible to every common capacity, and practicable to every farmer : it is also immaterial to him, whether his plants are fed by air, water, salts, or earth ; it is sufficient for him to know, that the vegetable nourishment, of whatever nature that is, will be obtained by good tillage and exposure ; whereof he may be soon convinced by his own experience ; and while he keeps this principle in view, he cannot greatly err in practice.

It has been known for ages, that the most perfect tillage was the best husbandry ; the ancient Romans recommend it highly, but they do not seem to have considered the reason that such tillage enriched the earth, or was preparative to it.

They also cultivated their vines by digging, ploughing, or hoeing : but the practice of hoeing all plants, while they are advancing in growth, and the surprising effects of it, is a late discovery. We find by the writings of several foreign gentlemen, how much they were surprised when they saw the effects of it upon a variety of plants so cultivated.

As this was so obvious in the culture of turnips, many farmers have extended it to other plants, as pease, beans, potatoes, and others, to the great improvement of their crops, and land also ; inasmuch that they have left off fallowing, by which they formerly lost one crop in three or four ; besides saving the expence of the fallow : for they now find, that by substituting hoed crops instead of fallowing, their lands yield good crops every year, an improvement of great importance to the farmers and to the public.

FOOT, the part that supports an animal.

A horse may have a very well made foot, and well proportioned, and yet if it chance to be thin and weak, the buyer will be disappointed of his expectation ; for such a foot is liable to be spoiled in shoeing, by travelling on hard stony grounds, by too much drought in hot seasons, or by too much moisture in winter. A thin foot is that where the crust or horn is thin, this may be easily seen when the shoe is taken off, because the verge all round the sole will appear thin ; and where it is so, a horse will winch with the least touch of the pincers ; but as this trial will seldom be allowed of in buying a horse, the best way to those who would be acquainted with such things, is to observe the bottom of the crust, which is generally ragged, and where the shoe-nails are clenched and rivetted : if these be high, it is a token the foot is thin, and that there has not been sufficient hold for the nails, without driving them a good way upwards in the crust. In a thin foot, the heel

and frog are also apt to be soft and tender to the touch, and by reason of the weakness natural to such kind of foot, it sometimes turns awry, and one point of the heel will stand higher than the other, though this may be also owing to the crookedness of the pastern joints, and will sometimes happen where the foot is tolerably strong ; but is most common to such as have weak feet ; and where it is so, the horse wears his shoes more on one side than the other, and often causes him to cut, and go lame in a journey.

As a thin weak foot is justly reckoned a very great defect in a horse, so a very strong foot is not always the most eligible, but is liable to several accidents. A strong foot has the fibres of the hoof very distinct, and for the most part run in a straight line from the coronet to the toe, like the grain of oak, lignum vitæ, or any other hard wood that easily splits ; and though some such feet will last very well, and keep free from accidents, where sufficient care is taken to keep them moist and pliable ; yet when they happen to be neglected upon a long journey, or much hard riding, especially on dry stony grounds, or when they stand long in a hot dry stable, they will go lame and tender, at the same time that no defect is to be seen on the foot ; for when the soft parts within are bruised by the hardness of the hoof, or by the thickness and hardness of the sole, which in all such feet is like a plate of iron ; and when this happens, a horse will be in pain, and the true cause sometimes not found out for a long time, which I have known in several instances ; nor is it easy to restore such feet to a due temperament.

When a horse that has a very strong foot takes up a channel nail, or happens to be cut into the quick with a sharp bone, a sharp flint, or piece of glass, and a flow of humours follows upon such a wound or puncture, the confinement these meet with from the strength of the foot create much anguish, and for want of vent below, frequently causes an eruption round the coronet, which proves for the most part troublesome, and makes the cure tedious and uncertain, especially when such cases happen to fall into bad hands.

I have known some instances where the hoof and the sole have been quite loosened from all their attachments to the foot, the filaments and fibres that unite the horny part to the flesh being all torn and pulled asunder by the thickness and strength of the horn ; and where this happens in any degree, it is apt to leave a tenderness behind it, unless an uncommon care be taken to prevent it.

But the greatest inconveniency in a very hard strong foot, is its being subject to rents, and fissures, which cleave the hoof quite through, sometimes from the coronet down to the bottom ; and this kind of foot is the more easily exposed to such accidents, that the horny fibres have a more visible straight direction than where the feet are more soft and pliable ; these clefts being for the most part in the quarter, seldom admit of any other remedy than extirpating the whole piece that lies next the heel, which defect is from thence called a false quarter, wherein the cure is seldom so perfect, especially in the fore feet, as to leave no infirmity or blemish behind it. When the fissure or cleft does not penetrate through the horn, but makes a line on the surface, it is called a sand-crack, being very common in some sandy countries, where the horse's hoofs turn dry and crack with the heat of the sand. These are but little regarded where the lines are superficial, and not deep in the horn, and are often cured by rasping the foot, and keeping it cool and moist. However, it is a defect that must lessen the value of a horse, in proportion to the degree of goodness or badness of his foot ; for when the foot happens to be otherwise bad, these blemishes often degenerate, and are of ill consequence.

The next defect I shall take notice of in the feet, is of those horses that have narrow heels. Some horses feet are tolerably good, even where the heels are narrow : but when the foot is hot and inclined to rotteness, and the quarters lose the round turn that they ought to have as they approach the heel, and look as if they were bent and pinched together, inasmuch that the heels of some such horses are not above two fingers in breadth, then the foot is bad ; and the way that many take to mend these kind of feet, by hollowing on each side the frog, and thinning the quarters to cause them to stretch to a wider shoe makes them worse ; for the stretching out the quarters contracts the hoof on the instep, and almost always turns such horses hoof-bound, and wire-heeled.

But horses often grow hoof-bound from other causes, and

and in some it proceeds from the shape of the coffin-bones when it happens to be flat or hollow, where it ought to be rising and round, when the coffin drops by thinning the sole too much, and not taking care to stay it up with stuffing and splinters, and from diseases in the feet that leave a weakness and deformity in them. But when a horse that has a very strong flinty foot happens to be hoof-bound, the case generally turns out bad. For the harder the hoof, the more it presses round the instep and heel. This pressure makes the parts all round the coronet to grow fleshy and project over the instep, so as to be constantly bruised by the upper part of the hoof, especially when a horse carries any great weight upon him, and by this means in the end engenders a quitter, which creeps so under the hoof that it can seldom be removed without the loss of a quarter, the same as when there is a fissure and cleft, or rather worse, because of the depression and binding all round the upper part of the foot with the distemper of the coronet, which often renders such cures both very tedious and imperfect. Therefore this ought to be well looked into, especially in choosing a saddle horse, that his feet be tolerably shaped, smooth, and cool, not narrow heeled, nor hoof-bound, neither weak-footed, nor too remarkably strong; for most horses of this latter kind are also coarse, and chiefly fit for labour.

Another thing that ought carefully to be looked into, is that both his fore-feet be of equal size; for wherever this defect is the least apparent, though it may proceed from a horse's using one leg more than the other, as it happens to working-men who use the right-hand and arm more than the left; yet when one foot is smaller than the other, it is a blemish, and carries some doubt that such a foot may in time fail and perish, even as those do that have been hurt by accidents, or after old lamenesses in the shoulders, legs, and muscular parts, where the foot at last perishes in proportion as the muscular and nervous parts shrink and diminish.

Another defect in horses feet, is when they are flat and without depth. If such a foot happens to be strong, and the hoof smooth, if the sole be also firm, and the frog no ways rotten or fleshy, such a horse will endure the roads tolerably well. But when a flat foot is shaped like an oyster, has many rings and wrinkles, if the sole be soft, and the frog fleshy and spongy, it is a very great defect. Some horses are so remarkably faulty in this respect, that the frog bunches out beyond the bottom crust of the hoof, that their shoes must be made hollow, and the plates so broad as almost to cover the whole bottoms of their feet, to keep them from the ground. But indeed such horses are only fit for draught, and not for the saddle.

Some horses have tolerable good feet, only that their heels are low. Horses that have long yielding pasterns are the most subject to this defect, and also those that have their pasterns very small, short, and standing almost quite upright; these have generally long heels and flat feet, and their fore-legs coming straight down from the shoulder to the foot, without any bending of the pasterns, and for this reason are frequently called goat-legged. Many of the horses bred in the fens are of this kind, have but an awkward use of their limbs, and make very bad travellers, and those low heeled horses which have very long yielding pasterns, are apt to have their heels wear quite to nothing upon a journey, and all the care imaginable in shoeing cannot prevent it.

A very high heel is another extreme, which greatly lessens the value of a horse; for even where such a foot happens to be strong and smooth, it is nevertheless the cause of unsteadiness in a horse's going, exposes him often to trip and stumble, to sprains in the coffin and pastern-joints, &c.

There is one kind of horse, especially among the coach and cart breed, very remarkable for a large deep foot; the horn extremely thick and scaly, the heels broad and mouldering, and are apt to grow so very fast, that the farriers when they go about to shoe such horses, thinking to ease them of their great load, and to bring their feet into a better size, pare and rasp them to such a degree, that they leave their feet much larger about the coronet and instep than at the bottom; so that they always look as if they went upon pattens, which is not only very ugly, but such horses are seldom good for much.

A very large foot of any kind is to be avoided in a horse, even supposing it to be in itself firm and good. But when I speak of a large foot, I mean only when it is

disproportioned to his other parts, for a large horse must of course have a larger foot than a small one. But when we see the foot large, and the limb small, in all such it must be observed by those who have experience, that the bones and sinews are also slender, which not only denotes weakness, but heaviness and inaptitude to any brisk and vigorous action; and therefore unfit for the coach, or saddle, but to draw in a cart or waggon, or to carry a burden.

Some object greatly against white feet, as being generally worse than those of any other colour. Indeed when a horse has too many of his feet white, they do not always prove the best, yet I have seen white-footed horses have their feet such as the ablest judges could not find fault with. When a foot is smooth and tough, of a middle size, without wrinkles, neither too hard and brittle, nor too soft, and when the heel is firm, open, and no ways spongy or rotten, and the frog horny and dry, and the sole somewhat hollow, like the inside of a dish or bowl, whatever be the colour, such a foot will for the most part turn out good, though the dark or black hoof, where it resembles that of deer, is generally the best; and for this reason those who are the most curious about a horse's feet, do not choose such as have much white upon their legs and pasterns, to avoid their having too many white feet. *Gibson's Farriery, vol. I. p. 19.*

FOOT-PATHS are a great injury to arable land. See PATHS.

FOSSE, a ditch or moat

FOSTAL, a way leading from the main road to a large house.

FOUL-FEEDING, a voracious appetite to which some horses are subject, and though not properly a disease, is often the cause of various maladies. It is generally the effect of some latent distemper, as vermin, which have a quite different effect on some horses to what they have on others; for as horses of a lax habit of body often lose their appetites by worms, and are frequently griped and sickly in their bowels; so horses of strong rigid constitutions, that can bear the irritation those animals make in their intestines, are often voracious in their appetites, and continually craving after food.

Foul-feeders, however, differ in some things from those that have voracious appetites: for as the latter crave only after their common food, and can hardly ever be satisfied; so the latter will leave their hay to eat their litter, and seem to like it the better when it is well sauced with their own dung and urine: and therefore, they may be properly said to have a vitiated or depraved appetite. Though this does not always proceed from a voracious appetite, yet the first is often productive of the latter, and may probably be occasioned by enlarging the capacity of the stomach and intestines to such a degree, that nothing will satisfy their cravings, but what has weight and solidity; for the same kind of horses will eat mould and wet clay, or any kind of foul nasty weeds out of the ditches, and in the stable will eat stinking musty hay, which the generality of horses will refuse.

There are others of depraved appetites, that are neither foul nor voracious feeders, such as we often observe eat dry loam or mud out of the walls, which perhaps denotes some vitiated juices in their stomach; and this also is frequently owing to vermin, or at least to a bad digestion, though perhaps not to any imbecility in their constitutions; for though those horses have a longing for those extraneous things, yet their appetites at the same time seldom fail: but as this is often owing to full feeding, with the want of sufficient exercise, so we often see them recover and quite lose that vitiated taste, when they come to ride a journey, or go upon any other constant exercise.

The best method in all these cases of a vitiated or depraved appetite, is to begin with purging, and to dissolve chalk in their water, and afterwards to give them good exercise. The same method may be complied with to those that feed voraciously. To these the following draught may also be given, to blunt their appetites:

Take a large handful of the roots of marshmallows, cummin-seeds, and fenugreek-seeds, of each an ounce; liquorice roots sliced, half an ounce; boil in three pints of water till the roots are soft and slimy, then pour off the decoction, and dissolve in it an ounce of gum-arabic, and add four ounces of linseed-oil.

Let

Let the horse have four handfuls of this every morning fasting, till his appetite abates. If the horse be lean, which many voracious feeders are, he will gather more flesh under this management, and as his flesh increases, his appetite will abate.

As to foul feeders, many of these begin with voraciousness, and when they come to be stinted, take to eating of their litter to fill their stomachs, and in time take a great liking to it; and it is observable, that many of the horses that go broken winded, have this evil faculty; and therefore I should advise any one who has a foul-feeding horse, to keep his stall as clean as possible, to let no wet, dirty litter, lie under him, nor to put his litter under the manger, but to bestow it on some other horse, otherwise they will paw it out, and feed upon it greedily; but clean straw that has not been soaked with horse-piss and filth, will never hurt any horse: for though there is no harm in the urine, yet when the straw has been soaked in it with the dung, it often turns into a wad, or like a sponge in their bowels, and causes great disorders. But when their wet litter is taken away every morning, it may be the means to make them leave off that ill habit. *Gibson's Farriery, vol. II. p. 96.*

To **FOUNDER** a horse, is to over-ride him, or to spoil him with hard working.

FOUNDERING in the feet, a distemper that affects a horse by means of hard riding or labour, or by heats and colds, which disorder the body, and excite malignant humours, that inflame the blood, melt the grease, and make it descend downwards to the feet, and there fettle; which cause a numbness in the hoof, so that the horse has no sense or feeling in it; and is hardly able to stand, and when he does he shakes and quakes as if he had an ague fit upon him; sometimes this malady proceeds from his being watered while he is very hot, and his grease melted within him, and then suddenly cooled by setting him upon cold planks without litter; or by taking his saddle off too soon, or else by letting him stand while hot in some shallow water up to the fetlocks; by means of which extraordinary coldness, it causes the melted grease to fall down into their feet, and their to cake and congeal.

A horse may also be foundered by wearing strait shoes, and by travelling upon hard ground.

The symptoms by which you may know when your horse is foundered upon his fore feet, and not his hind feet, is by his treading only upon his hind feet, and as little as he can upon the other; or his going crouching and crumpling upon his buttocks; and when sometimes he is foundered upon his hind feet, and not upon his fore feet, (which happens but seldom) it may be known by his seeming weak behind, and his resting himself as much upon his fore feet as he can; being afraid to set his hinder feet to the ground.

The general method of cure is: first, to pare all the horses's soles so thin that you may see the quick: then to bleed him well at every toe, stop the vein with tallow and rosin, and having tacked hollow shoes on his feet, stop them with bran, tar, and tallow, as boiling hot as may be; repeating this every other day for a week together, and afterwards to give him good exercise, &c.

CHEST-FOUNDERING, a distemper proceeding from crudities in the stomach, or other weaknesses obstructing the passage of the lungs.

This is discovered by the horse's often coveting to lie down, and standing straggling with his fore legs; the symptoms being much the same as in purfiness; the only difference is, that young horses are subject to chest foundering as well as old; whereas, those horses which are troubled with purfiness are generally six years old and above.

Grass, with refreshing and cooling diet, cures the former, but encreases the latter.

The cure: take five or six pennyworth of oil of petre, and mingle it with an equal quantity of ale or beer, and with your hand rub this mixture on the part affected, a red hot fire-shovel being held against it while you are rubbing it.

FOUNDERING in the body, is caused by a horse's eating too much provender suddenly, while he is too hot and panting, so that his food not being well digested, breeds ill humours, which by degrees spread themselves all over his members, and at length does so oppress his body that it renders him extremely weak, and makes him incapable of bowing his joints; and when he has laid down cannot rise again; nor can he either stale or dung without great pain.

It is also caused by drinking too often upon a journey while he is hot, not being ridden after it.

The symptoms are, the horse will be chilly and quake for cold after drinking; and some of his drink will come out at his nose, and in a few days his legs will swell, and after a while begin to peel; he will have a dry cough, his eyes will water, and his nose run with white phlegmatic stuff, he will forsake his meat, and hang down his head for extreme pain, in the manger.

For the cure: first, rake the horse's fundament and give him a clyster; then put half an ounce of cinnamon, and of liquorish and aniseeds each two spoonfuls in fine powder, and five or six spoonfuls of honey into a quart of ale or sack, set it on the fire till the honey is melted, and give it him lukewarm to drink, riding him afterwards gently for an hour, clothe him and litter him warm, and keep him fasting for two hours more: sprinkle his hay with water, sift his oats clean from the dust, and give it him by little and little: let him drink warm meshes of malt and water; and when he has recovered strength, bleed him in his neck vein, and perfume his head with frankincense once a day.

FOWL, a general name for all sorts of birds; but used in a particular sense to signify such as are bred in the farmer's yard for profit.

The countryman's farm or habitation cannot be said to be compleatly stored or stocked without fowl as well as beast, which yield a considerable advantage by their eggs, brood, bodies, and feathers. Any poor cottager that lives by the high-way-side may keep them, they being able to shift for themselves the greatest part of the year, by their feeding on insects, corn, or any thing almost that is eatable by any other sort of animal: and therefore they are kept to great advantage at barn-doors, and other places, where corn or straw is scattered.

As for cocks and hens, we shall not enter into a description of the several sorts of them, only observe that those that are the best breeders, and the best layers, are to be chosen, the oldest being always the best sitters, and the youngest the best layers; but no sort will be good for either if they are kept too fat. The best age to set a hen for chickens, is from two years old to five; and the best month to set them in, is February, though any month between that and Michaelmas is good. A hen sits twenty days; whereas geese, ducks, and turkeys, sit thirty. Observe to let them have constantly meat and drink near them while they sit, that they may not straggle from their eggs, and chill them. One cock will serve ten hens.

If fowls are fed with buck or French wheat, or with hemp, canary, or millet-seed, which is commonly sown in March, it is said they will lay more eggs than ordinary; and buck-wheat, either whole or ground, and made into paste, which is the best way, is a grain that will fat fowls or hogs very speedily; but the common food to fat them with is barley-meal wet with milk or water; but wheat-flour is better: yet if you design to bring up chickens, give a barley-corn or two to each of them, as you take them out of the nest, and so continue to feed them till they are fit for fattening.

For the best methods of breeding ducks, geese, turkeys, pigeons, swans, peacocks, &c. See **POULTRY**, and each under its proper article **DUCKS**, **GEES**, **TURKEYS**, &c.

FOWL's Dung. See the article **Dung**.

FOX, a well known animal of the canine kind, with sharp ears and a bushy tail.

The fox is very prejudicial to the husbandman, by taking away, and destroying of his lambs, poultry, geese, &c. especially in places that are near forest-woods, and covert places. The best way of destroying them is with guns or traps, after this manner: if you design to shoot them, procure a sheep's paunch, and tying of it to a long stick, rub your shoes well upon it, that the fox may have no scent of your feet, and draw the paunch after you, with which make a trail a mile or two in length; and order it so as to bring it near some thick-headed tree. At which place, when you have made your trail, leave your paunch, and with your gun get up into the tree; and as soon as it begins to be dark, you will see him come by you upon the scent of the trail, where you may shoot him. Observe that you draw the trail to windward of the tree, if you can.

But if you have a mind to catch them with a steel-trap, which is the surest way, choose a place to set it in a plain part of a large field; let it be out of the way of all paths, but not near either a hedge or any shelter. Open your trap, and lay it upon the ground, and cut out in the turf just the form thereof, and take out so much earth as may make room to lay it, covering it again very neatly with

the turf you cut out; and because the joints of the turf will not close exactly, get some of the fine mould that is to be found in a new cast up mole-hill, and fill the joints with it, taking some grass, and sticking it in the mould, as if it grew there. Make all so fine and plain, as that it may deceive your own eye to look upon it. About eight or ten yards from the trap, three several ways, scatter some of the fine mould that you had out of the mole-hill, very thin upon a place about fourteen or fifteen inches square; and upon these places, and where the trap is, lay two or three small bits of cheese, and with a sheep's paunch, as is before directed, draw a trail of about a mile long to each of the three places, that are at a distance from the trap, and from thence to the trap, that so the fox may come upon one of those places first, which will make him approach the trap with more boldness, where you will seldom fail of him; only you must observe not to fasten your trap, but to leave it loose, that he may draw it to the hedge-side, or to some cover, or else he will bite off his leg, and be gone.

Some bend down a stick in the wood, and set a trap for them in their paths, like that which is set for woodcocks, which hangs them up, or any other sort of vermin. *Mortimer's Husbandry*, vol. I. p. 312.

FOX-TAIL GRASS, the same with cow-wheat. See the article **COW-WHEAT**.

FREE-MARTIN, a barren heifer; being a twin with a bull-calf.

FRENCH BARLEY, a species of barley called by botanists *tritico speltum*. Some call it wheat-barley. It is naked, and the grain like wheat, but the ear shaped like that of the common barley. This species is often sown about Rowley, Hamstal, and Redmore, in Staffordshire. It yields a large increase, and makes good bread and good malt. See the article **BARLEY**.

FRENCH BEANS. See the article **BEANS**.

FRITH, an arm of the sea running into the land.

FROST, the last effect of cold; the power or act of congelation.

Frost is a great fertilizer of land, and therefore when the soil is a harsh, churlish, or obstinate clay, it should be turned up in ridges at the beginning of winter, which will greatly tend to remove its bad qualities, and separate its particles.

Hard winters are generally of service to corn in many respects; especially if the land has been thoroughly drained, and is well covered with snow. This last mellows the ground and keeps it warm; while frost, neither the rigour nor duration of which need be feared if it comes on gradually, and the land is dry, not only kills great numbers of vermin and insects, but, by leaving the earth in a loose state, fits it for roots to extend themselves therein, as the warmth of the spring approaches, and thereby enables them to produce strong plants; whereas frequent rains in winter, without frost, sodden the earth, which afterwards produces nothing but blades, soon to be destroyed by the hoar frosts of the spring, by insects, and by weeds; or which would yield at most only straw without grain. The winter's frosts may indeed nip off the blades; but then the roots being unhurt, new ones will shoot up in the spring. This was the case in the remarkably severe winter of 1608, of which Mezeray speaks, and which, notwithstanding its extreme severity, was followed by a plentiful harvest; and such also, or nearly such, was the long winter of 1739.

The great danger from frosts is, when the earth is wet, and not covered with snow. For example, if a strong frost returns after a sudden thaw, the fibres of the roots are broken by the expansion of the surrounding water when frozen, and the too great abundance of moisture in the plants themselves when frozen, tears their fibres to pieces by the same expansion. This was what happened in 1684.

Early in the spring of 1710, the parliament of Paris, hoping that the corn cut off by the preceding winter would shoot out again, as it did after the winter of 1608, mentioned by Mezeray, forbid sowing anew the lands which had been sown the autumn before: but the expectation now proved groundless, the plants having been totally destroyed by repeated frosts, intermixed with frequent thaws, so that had it not been for the barley that was sowed afterwards, which yielded such prodigious crops, that the French still call that year the year of barley, the dearth must have been much more dreadful than it was. In that very spring, after the hard winter, several people in the dutchy of Berry, and elsewhere, sowed wheat, which

sprouted well, and grew, but did not spindle; whereupon, some mowed their crops, and others turned in cattle to feed as in a meadow: but after another winter had passed over them, these very fields yielded the next year as plentifully, as if they had been sown anew. In inclosed grounds, the corn near hedges, which secured it from the north wind, resisted all the rigour of that excessive cold; and in other places, where the poor peasants raked up all the snow they could collect, and spread it with their hands upon the uncovered spots of their small fields, their corn was preserved, and yielded a good crop.

A gentleman, now living in England, had a field of wheat so greatly damaged by alternate frost and thaw, that the neighbouring farmers thought he could not do better than plough it up for spring corn; but observing that many of the plants were yet alive, and in a condition to be recovered, though thinly scattered, he hand-hoed the whole, and reaped three quarters of corn from each acre of this land.

Wheat is very hardy, and rarely injured by frost, if the land upon which it grows is not wet. In the great frost of the year 1739-40, the frost was often intense in the nights, and in the days a bright sun-shine; these alternate changes reduced the surface of the land to dust, which was so light, that the wind blew the mould off the south sides of the ridges that lay east and west; but on the north sides, that were not so much exposed to the sun, the mould not being so much pulverised, was not blown off, and the wheat there was very little hurt; while the roots of the wheat on the south sides was laid bare, and the plants in general were killed by the frost. The blades of all the wheat were destroyed, and nothing green to be seen, and many farmers ploughed up their wheat, thinking it was all dead: others, more curious, finding upon examination, that the roots were still alive, suffered their wheat to remain, which, upon the frost going off, recovered, shot up new stalks, which branched greatly, and produced very large ears, and very full grained corn, so that upon the whole there was a plentiful crop. From this and other instances it appears, that wheat upon dry healthy land is not killed by frost, unless its roots are all, or most of them, exposed to it.

Mr. Marshall, in his Minutes of Agriculture, makes the following remarks, "October 3. 1785. The barley had not ripened, perceptibly, for some weeks before the late sharp frosts; since which it has ripened daily. There are twice the number of ripe ears, now, there were a week ago: they are not only changed as to colour, but the corn is obviously plumper. Before the frosts, the heads seemed slender and puny; so much so, that I had consigned the whole to the miller: now I begin to hope that some of it may, this year of scarcity, be fit for the maltster."

"It was a general observation, it seems, in this country, in the year 1782, (a wet backward summer) that the late ripe crops did not ripen until frost came: even wheat was cut in December."

"How is this to be explained? Frost, we scarcely can doubt, compresses the sap vessels of vegetables, and, probably, forces the sap out of them, back to the earth, it is generally supposed; but, perhaps the natural receptacles of the plants are first supplied."

"It is observable that fruits ripen, leaves fall, lattermath shrinks, by frost."

FROWAR, the name of an edge tool, used in cleaving laths.

FRUNDELE, two pecks, or half a bushel.

FRUSHES. See **RUNNING-THRUSH**.

FUDDER, a load. It properly relates to lead, and signifies a certain weight, viz. eight pigs, or sixteen hundred weight.

FULLERS EARTH, a native earth found in many parts of England, and much used by fullers in cleaning and scouring their cloth. It is of a very fat nature, and very full of that vegetative salt that helps the growth of plants; and therefore may be used with advantage, where it is found in plenty, on some sorts of land.

FURLONG, the eighth part of a mile.

FURROW, a trench made by the plough.

FURROWING PLOUGHS. Of these, Mr. Young, in his Annals of Agriculture, Vol. IV. says, "That used for pease makes only one furrow at a time, and drills the pease; with the same plough the bean furrows are made, but, instead of drilling, they are dropped. The plough used for wheat, barley, oats, and canary (and one plough answers

answers the purpose for these several sorts) makes two furrows at a time; the seed is then sowed by hand, and grows regularly in them. The barley I generally drill, not sow. It must be harrowed with the furrow. Observe, I dung my clover-lay, and plough it six weeks or two months before I furrow and sow canary, and if the ground is well ploughed, there is not any the least difficulty in furrowing a clover lay. What I mean by ploughing well, is making small furrows, and laying them with a comb; not great, broad, flat furrows."

FURZE, *whins* or *gorse*, to which C. Bauhin and Mr. Ray, gives the name of *genista spinosa*, and which Linnaeus and Miller call *ulx*, propagate themselves so rapidly, by sowing their seeds, that, where they are once established in a spot of ground, they soon over-spread the whole place; for, as the seeds ripen, their pods are opened by the warmth of the sun, and they are thrown out with an elastic jirk to a considerable distance all around. There they vegetate, and the ground is soon filled with young plants, which are not easily destroyed after they have taken good root. The only way of extirpating them, is by paring off and burning the surface of the ground. See the article BURN-BAKING.

This is by so much the more advisable, as these seeds will otherwise remain a long while found in the earth, and grow whenever they are brought up by ploughing; and also because the smallest fragments of this plant will strike out fresh roots, and shoot up anew; but when a good thickness of the surface is pared off, and burnt, the seeds are so effectually destroyed, and the roots are killed to so considerable a depth, that neither can again give rise to new plants; and if a few of these do appear, a summer fallow will put an entire end to their growth. Their increase may likewise be prevented by good manuring with marl, chalk, or lime, especially in sandy soils, which are most apt to produce this plant, and which are at the same time the most benefited by these helps.

However, this very plant, formerly deemed a great nuisance, is now cultivated to advantage on light, sandy, dry soils, which would otherwise turn to little account.

The tops of the common English furze, bruised a little to take off, or to blunt their prickly tips, have been found to be excellent fodder, even for lean sickly beasts, and particularly horses, which they have frequently recovered, and plumped up in a short time. This custom is much practised in several foreign countries, where furze are cultivated purposely for fodder; and the peasant thinks it a happiness that his breaking their pipes with a mallet enables him to give this wholesome green food to his cattle in the winter, when often no other succulent plant can be had fit for that use. The mills which Sir Capel Hanbury has lately erected for this end in Wales, with a patriotic spirit, well suited to his distinguished zeal for the public welfare, will save the countryman that laborious task, and prove highly beneficial to those who follow his judicious example.

When furze are raised on purpose for the food of cattle, and especially on soils like the above mentioned, their seeds should be sown in February, March, or April, and the ground should be prepared as for barley. Six pounds of them will be sufficient for an acre of land; and they should be but barely covered over. The young plants must be preserved from cattle during the first year, and they will be fit to mow or cut in the next. October is the proper time to begin cutting them. They will con-

tinue to shoot till Christmas, and be fit for use till March. Horses eat them as readily as they do hay, after they have been bruised, or pounded, so as to take off their sharp points; and it is said, that an acre of ground, will produce fifteen tons of this fodder, and it will go as far as an equal quantity of hay. Some mix the bruised furze with chopped straw; an hundred of straw to a ton of furze; but only the growth of the year should be cut for cattle.

Poor hungry gravelly soils, which would not have let for five shillings an acre, have been rendered worth twenty shillings an acre, by sowing of them with furze seed, in places where fuel has been scarce; this being frequently used for heating ovens, burning lime and bricks, and also for drying malt; but it is not worth cultivating in countries where fuel of any kind is cheap, or upon such lands as will produce good grass or corn.

Some years ago, the common furze used to be much sown for hedges about fields; and where the soil was light, the plants soon became strong enough for a fence against cattle: but as these hedges grow naked at the bottom in a short time, and the plants frequently failed, so as to leave considerable gaps, this practice has of late been greatly disused. The species commonly called French furze is the best for this purpose, because it thickens more near the ground, and grows to a greater height; but its shoots are not tender enough for cattle to eat them. This is also considered as the most difficult to extirpate; though Mr. Bradley, who tells us he had seen fields of one hundred and fifty acres planted with it in Devonshire, says, that it may be killed by cutting the woody stalks within a foot of the root in summer time; for that it will not then spring up again like the small wild furze or whins, by which name Mr. Markham distinguishes the smaller from the larger sort. This begins to blow in the middle of January, and continues in blossom all the summer; while the English furze does not bloom till towards the end of the spring, and finishes its blossoming at the same time as the other.

The marquis of Tourbilly observes, that cows, oxen, and most other cattle, as well as horses, feed heartily upon, and are well fed by the bruised tops of furze; and that we may be sure corn will do well wherever this plant is met with: for be the surface of the ground what it will, the spontaneous growth of the furze always indicates a depth of good mould underneath; and the continual dropping and rotting of the leaves, will infallibly improve and enrich the surface. The flowers of the furze are excellent for bees.

FURZE GROUNDS. Mr. Marshall, in his Rural Economy of Yorkshire, Vol. I. says, "It is the opinion of one who has paid close attention to the subject, that old furze-grounds, off which fuel having been repeatedly carried, are of course much depauperated, may in general be improved in the following manner:

"Grub; sow grass seeds, on the grubbed surface, without ploughing; and let the land remain in this state until it has acquired a degree of firmness, the smaller roots left in it are decayed, and the surface has got a covering. Then sod-burn, lime, &c. and break up the soil for a course of arable crops; closing with cultivated grass. When the furzes begin again to grow troublesome repeat the sod-burning."

FUZZEN, or FUZEN, the natural juice or nourishment of any thing; the strength of it.

G.

GALLERY, a kind of covered walk in a garden, formed into porticoes or arches, with horn-beams, lime-trees, or the like.

GALLING of a horse's back, a disorder occasioned by heat, and the chafing or pinching of the saddle.

In order to prevent it, some take a hind's skin well covered with hair, and fit it neatly under the pannel of the saddle, so that the hairy side be next the horse.

This does not harden but sweat, and so not only keeps that part from galling, but is good for such horses as have been lately cured, which would otherwise gall again.

After a journey you ought to take off the saddle and feel the horse's back, whether he has been pinched or galled or not, which will be the best discovered after he has stood an hour or two unsaddled, by the swelling of the part oppressed.

If it be only swelled, fill a bag with warm dung, and tie it upon the swelling, which will not only prevent it from growing worse, but also probably quite disperse it.

Or you may rub and chafe the swelling with good brandy, or spirit of wine, and having soaked the place well with it, set fire with a lighted paper to what remains of it, and the swelling will disappear, when the fire extinguishes of itself; but if the skin be broke, wash it with warm claret, mixed with a fourth part of fallad oil, or fresh butter; or bathe it often with brandy if the horse will endure it.

When a horse's back is galled upon a journey, take out a little of the stuffing of the pannel over the swelling, and sew a piece of soft white leather on the inside of the pannel; anoint the part with salt butter, and every evening wipe it clean, rubbing it till it grow soft, anointing it again with butter, or, for want of that, with grease: wash the swelling, or hurt, every evening with cold water and soap, and strew it with salt, which should be left on till the horse be saddled in the morning.

GALLON, a measure of capacity both for dry and liquid things, containing four quarts; but these quarts, and consequently the gallon itself, are different, according to the quality of the thing measured: for instance, the wine gallon contains 231 cubic inches, and holds eight pounds avoirdupoise of pure water: the beer and ale gallon contains 282 solid inches, and holds ten pounds three ounces and a quarter avoirdupoise, of water; and the gallon for corn, meal, &c. 272 cubic inches, and holds nine pounds thirteen ounces of pure water.

GALLOWS of a plough, a part of the plough-head so called by farmers, from its resemblance to the common gallows, as consisting of three pieces of timber, of which one is placed transversely over the heads of the other two. See **PLOUGH**.

GAME-LAWS. For the information and satisfaction of all gentlemen farmers, and others, we have here inserted abstracts of all the acts of parliament relating to the game, whereby they and sportsmen may know the respective times when they are to begin, and when they are to leave off sporting, and also the penalties and punishments of infringing or breaking the above acts. Agreeable to the act of 24 Geo. III. certificates required before the first day of October, 1784, shall bear date on the day of the month on which the same shall be issued, and shall remain in force until the first day of July next following. No certificate shall issue between the first day of October, 1784, and the first day of March 1785; and every certificate which shall issue after the said first day of March, 1785, shall be issued between the first day of March and the first day of July in each year, and shall bear date on the day of the month on which the same shall be issued, and shall be in force for twelve calendar months, commencing from the date; and if any clerk of the peace, his deputy, or steward clerk, issuing certificates, otherwise than directed, to forfeit 50*l*. 24 Geo. III. *sess*. 2. c. 43. f. 5. But certificates may issue

to any person beyond the seas, who hath, or shall have, in any year, first arrived into England, any time after the first day of July in such year; but in every such case, the cause shall be specified, either in the body or at the foot of such certificate; to bear date on the day it is issued, being stamped with double duties, and to be in force till the first day of July next following the date thereof, 24 Geo. III. *sess*. 2. c. 43. f. 6. Every qualified person, after the said first day of October, 1784, shooting at, killing, taking, or shooting any pheasant, partridge, heath-fowl, or black game, or any grouse, or red game, or any other game, or killing, taking, or destroying, any hare, with any greyhound, hound, pointer, spaniel, setting-dog, or other dog, without having obtained such certificate, shall forfeit the sum of 50*l*. 24 Geo. III. *sess*. 2. c. 34. f. 7. Clerk of peace, &c. shall on or before November 1, 1784, and in every subsequent year, on or before August 12, in each year, make out and transmit to the stamp office, London, alphabetical lists of the certificates so granted by them, distinguishing the duties paid on each respective certificate so issued, and on delivery thereof, the receiver-general of the stamp duties shall pay to clerk of peace, &c. for the same, one farthing a name; and in case of neglect or refusal, or not inserting a full, true, and perfect account, he shall forfeit 20*l*. 24 Geo. III. *sess*. 2. c. 43. f. 9. Lists may be inspected at stamp office for 1*s*. each search, 24 Geo. III. *sess*. 2. c. 43. f. 10. If any qualified person, or having a deputation, shall be found in pursuit of game, with gun, dog, or net, or other engine for the destruction of game, or taking or killing thereof, and shall be required to shew his certificate, by the lord or lady of the manor, or proprietor of the land whereon such person shall be using such gun, &c. or by any duly appointed game-keeper, or by any qualified and certified person, or by any officer of the stamps, properly authorised by the commissioner, he shall produce his certificate; and if such person shall refuse, upon the production of the certificate of the person requiring the same, to shew the certificate granted to him for the like purpose; or in case of not having such certificate to produce, shall refuse to tell his christian and surname, and his place of residence, and name of the county where his certificate was issued, or shall give in any false or fictitious name, he shall forfeit 50*l*. 24 Geo. III. *sess*. 2. c. 43. f. 12. Certificates do not authorise any person to shoot at, kill, take or destroy any game, at any time that is prohibited by law, nor give any person a right to shoot at, &c. unless he be duly qualified by law, 24 Geo. III. *sess*. 2. c. 43. f. 13. No certificate, obtained under any deputation, shall be pleaded or given in evidence, where any person shall shoot at, &c. any game out of the manor or lands for which it was given, 24 Geo. III. *sess*. 2. c. 43. f. 14.

Lord Mansfield has given it as his opinion, that an unqualified person may go out to beat the hedges, bushes, &c. with a qualified person, and to see the game pursued or destroyed, provided the unqualified person has no gun or other engine with him for the destruction of the game, without being subject to a penalty.

Destroying conies, transportation, 5 Geo. III. c. 14. Robbing warrens, felony without clergy, 9 Geo. I. f. 22. Killing them in the night, or endeavouring to kill them, fine of 10*s*. or commitment, 22 and 23 Car. II. c. 25. f. 5, 6. Unqualified persons using guns to kill them, same may be seized, 3 Jac. I. c. 13. f. 5. Stalking deer without leave, 10*l*. 19 Hen. VII. c. 11. Hunting or killing them, 10*l*. costs, and sureties for good behaviour, 5 Eliz. c. 21. Buck-stalls or engines kept by unqualified persons, may be seized, 3 Jac. I. c. 13. Selling, or buying them to sell again, 40*s*. 3 Jac. I. c. 27. Courting, or killing them without consent, 20*l*. 13 Car. II. c. 10. Hunting, taking, killing, or wounding, 30*l*. or transportation, 3 Will. III. c. 10. 5 Geo. I. c. 15. 9 Geo. I. c. 22. 10 Geo. II. c. 32. Destroying pales or walls of inclosed grounds without consent,

sent, 30*l.* 5 *Geo. I. c. 15. f. 6.* Keeper of park killing or taking them, 50*l.* 5 *Geo. I. c. 15.* Robbing places, where kept, felony without clergy, 9 *Geo. I. c. 22.*

All lords of manors or other royalties may appoint game-keepers, 22 and 23 *Car. II. c. 25. f. 2.* and empower them to kill game, 2 *Burn's Just. 225.* But if he disposes of game without the lord's consent, he shall be committed for three months, and kept to hard labour, 5 *Anne, c. 14. f. 4.* But no lord shall make above one game keeper within one manor, with power to kill game, and his name shall be entered with clerk of peace; certificate whereof shall be granted by clerk of peace, on payment of one shilling. Unqualified game-keepers killing or selling hare, pheasant, partridge, moor, heath-game, or grouse, he shall forfeit 5*l.* by distress, or commitment for three months, for the first offence, and for every other four, 9 *Anne, c. 21. f. 1.* No lord shall appoint unqualified game-keeper, or one who is not *bona fide* servant to such lord, or immediately employed and appointed to take and kill game for the sole use of lord; other persons under colour of authority for taking and killing game, or keeping any dogs or engines whatsoever for that purpose, shall forfeit 5*l.* In like manner, 3 *Geo. I. c. 11. f. 1.* Every deputation of a game-keeper to be registered with clerk of the peace, or in the sheriff or steward's court-books of the county where lands lie, and annually take out certificate thereof, stamped with an half-guinea stamp, 24 *Geo. III. f. 2. c. 43. f. 1.* and by the 31 of *Geo. III. c. 21.* with an additional half-guinea stamp, making in the whole one guinea. Every game-keeper, from and after the passing of this act, who shall so deliver his name and place of abode as aforesaid, and require a certificate, shall be annually entitled thereto, stamped as before directed, from clerk of peace or his deputy, sheriff, or steward's clerk to the effect of the form in the act set forth, 24 *Geo. III. f. 2. c. 43. f. 3.* Clerk of peace, &c. after signing certificate, shall issue same stamped to person registering deputation, on requiring same, for which he may receive 1*s.* 24 *Geo. III. f. 2. c. 43. f. 4.* Neglecting, or refusal of issuing certificates, incurs a forfeiture of 50*l.* 24 *Geo. III. f. 2. c. 43. f. 4.* recoverable in courts of *Westminster*, court of Session, of Justiciary, or Exchequer in *Scotland*, by action of debt or information, for the use of the plaintiff, with double costs of suit, 24 *Geo. III. f. 2. c. 43. f. 18.* And moreover be liable to pay the duty on such certificate, 24 *Geo. III. f. 2. c. 43. f. 4.* Clerk of peace, &c. may issue his certificate to any game-keeper first appointed in any year after first *July* in that year, 24 *Geo. III. f. 2. c. 43. f. 6.* If any lord or lady of a manor, or proprietor of land, shall make any new appointment of a game-keeper, and shall register deputation with clerk of peace, &c. and obtain a new certificate thereon, the first shall be void; any person acting under the same, after notice, shall be liable to all the penalties of the game-laws, and those against unqualified persons, 24 *Geo. III. f. 2. c. 43. f. 11.*

Every person tracing or coursing hares in the snow shall be committed for one year, 31 *Eliz. c. 5.* unless he pay to church-wardens, for the use of the poor, 20*s.* for every hare, or become bound by recognizances with two sureties in 20*l.* a-piece, not to offend again; and every person taking or destroying hares with any sort of engine, shall forfeit, for every hare, 20*s.* in like manner, 1 *Jac. I. c. 27. f. 2.* Persons found using engines liable to punishment inflicted by 31 *Eliz. c. 5.* See above, and 22 and 23 *Car. II. c. 25. f. 6.* Unqualified persons keeping or using shooting dogs, or engines to kill or destroy hares, shall forfeit 5*l.* to the informer, with double costs, 2 *Geo. III. c. 19.* by distress, or committed for three months for first offence, and for every other four, 5 *Anne, c. 14. f. 4.* Taking or killing hare in the night-time, forfeit 5*l.* 9 *Anne, c. 25. f. 3.* The whole to the informer, with double costs, 2 *Geo. III. c. 19.* as directed by 5 *Anne, c. 14. f. 4.* 9 *Anne, c. 25. f. 3.* Killing or taking with gun, dog, or engine, hare in the night, between the hours of seven at night and six in the morning, from *October 12* to *February 12*, and between the hours of nine at night and four in the morning, from *February 12* to *October 12*, or in the day-time upon *Sunday* or *Christmas-day*, to forfeit not less than 10*l.* nor more than 20*l.* for the first offence; nor less than 20*l.* nor more than 30*l.* for the second offence; and 50*l.* for the third offence; with costs and charges; and upon neglect or refusal, be committed for six or twelve calendar months, and may be publicly whipped; final appeal to quarter sessions, 13 *Geo. III. c. 80.* Persons armed and disguised, stealing them, felony without clergy, 9 *Geo. I. c. 22.* Higler, chapman, carrier,

inn-keeper, victualler, or alehouse-keeper, having in his custody, or buying, selling, or offering to sale, any hare, unless sent up by some person qualified, (or any person selling, exposing, or offering to sale, hares, 28 *Geo. II. c. 22.*) shall forfeit for every hare, 5*l.* the whole to informer, 2 *Geo. III. c. 19.*

For preserving heath-cocks or polts, no person whatsoever, on any waste, shall presume to burn, between *February 2* and *June 24*, any grig, ling, heath, furze, goss, or fern, on pain of commitment for a month, or ten days, to be whipped and kept to hard labour, 4 and 5 *W. and M. c. 23. f. 11.* Shooting heath-cocks, grouse, or moor-game, contrary to 1 *Jac. I. c. 27. f. 2.* and killing any of them in the night, or using gun, dog, or engine, with such intent, contrary to 9 *Anne, c. 25.* and 13 *Geo. III. c. 80.* And carriers and others having such game in their possession, contrary to 9 *Anne, c. 14.* are all liable to the same penalties, and recoverable in the same manner as those offences are subjected to in regard to shooting, &c. hares.

Officers of the army, without leave of the lord of the manor, destroying coney, hare, pigeon, pheasant, or partridge, or his Majesty's game, shall forfeit 5*l.* to the poor; and the commanding officer, for every offence, committed by any soldier under his command, shall forfeit 20*s.* in like manner; and if, upon demand, he shall not in two days pay said penalty, he shall forfeit his commission. *Vide* The yearly Mutiny Act.

Taking partridges, by nets or other engines, upon another's freehold, without special licence of owner of same, 10*l.* half to him who shall sue, and half to owner or possessor, 11 *Hen. VII. c. 17.* Shooting at, &c. partridges, with gun or bow, or taking, &c. them with dogs or nets, by 7 *Jac. I. c. 11.* or taking their eggs out of their nests, liable as persons shooting at, &c. hares, and also 20*s.* for every bird or egg, as is shewn in the preceding column concerning Hares. Selling, or buying to sell again, a partridge, (except reared and brought up in houses, or from beyond sea) forfeit for every partridge 10*s.* half to him who will sue, and half to informer, 1 *Jac. I. c. 27. f. 4.* Taking, killing, or destroying partridges in the night, forfeits for every partridge, 10*s.* half to him who will sue, and half to lord of the manor, unless he licence, or cause the said taking or killing, in which case this half shall go to the poor, recoverable by church-warden; and if not paid in ten days, to be imprisoned for one month; and moreover, shall give bond to justice, with good sureties not to offend again for two years, 23 *Eliz. c. 10.* To kill a partridge in the night is 5*l.* penalty, 9 *Anne, c. 25. f. 3.* the whole whereof is given to the informer, 2 *Geo. III. c. 19.* and may be recovered within three months, 5 *Anne, c. 14.* before a justice of peace, or within six months, by action in Court of Record at *Westminster*, 9 *Anne, c. 25.* with double costs, 2 *Geo. III. c. 19.* Keeping or using any greyhounds, setting-dogs, or any engine for destroying partridges, 5*l.* to be levied and recovered as the like penalty for killing hares, by 5 *Anne, c. 4. f. 4.* as before is shewn. Penalties for using gun, dog, snare, net, or other engine with intent to take or destroy partridges in the night, or on *Sunday* or *Christmas-day*, same as using them against hares, by 13 *Geo. III. c. 80.* as in the foregoing column. Carriers and others having partridges in their possession, liable to same forfeitures as having hares; and the same laws against shooting them as for shooting hares.

All the laws respecting the penalties and recovery of them, for taking them by nets, snare or other engines, without license of the owner, by *Hen. VII. c. 17.* And for shooting, or destroying them with dogs or snares, &c. by 7 *Jac. I. c. 11.* or taking their eggs, by 1 *Jac. I. c. 27. f. 2.* And for selling, and buying them to sell again, by last cited act (except that the penalty for a pheasant is 20*s.*) and for destroying them in the night (excepting as aforesaid,) by 23 *Eliz. c. 10.* 9 *Anne, c. 25. f. 3.* and 13 *Geo. III. c. 80.* And for keeping or using sporting-dogs or engines for destroying them, by 5 *Anne, c. 14. f. 4.* Or for using gun, dog, or net, for destroying them on *Sunday* or *Christmas-day*, by 13 *Geo. III. c. 80.* and for carriers and others having them in their possession; all these laws are *mutatis mutandis verbatim*, the same as those respecting partridges.

Person prosecuted for any thing done in pursuance of this act, he may plead the general issue, and give the special matter in evidence for his defence; and if upon trial verdict puts for defendant, or plaintiff become non-suited, defendant shall have treble costs of plaintiff, 24 *Geo. III. f. 2. c. 3. f. 24.*

Qualifications for killing game (besides the late new tax) are, 1. Having a freehold estate of 100*l.* *per annum*, 22 and

23 *Car. II. c. 25.* 2. A leasehold estate, for 99 years, of 150*l. per annum.* 3. The eldest son or heir-apparent to an esquire, or person of superior degree. 4. The owner or keeper of a forest, park, chace, or warren. See *Bl. Com.* 174, 175. Unqualified person keeping dogs or engines to destroy the game, to forfeit 5*l.* 5 *Anne, c. 14.* Restrictions in the laws concerning the preservation of game, seems to affect all persons whomsoever, whether qualified or not, 2 *Burn's Just.* 219, 248. No person (other than the King's son,) unless he have lands of freehold to the value of five marks a year, shall have any game of swans, on pain of forfeiting them, half to the king, and half to any person (so qualified) who shall seize the same, 22 *Edw. IV. c. 6.* Any gentleman or other that may dispend 40*s.* a-year freehold, may hunt and take wild-fowl with their spaniels only, without using a net or other engine, except the long-bow, 25 *Hen. VIII. c. 11.* From persons not having lands of 40*l.* a-year, or not worth in goods 200*l.* using gun or bow to kill deer, any person having 100*l.* may seize same to his own use, 3 *Jac. I. c. 13.* Killing in the night, between the hours of nine at night, and four in the morning, from February 12 to October 12, any game, by any person, whether qualified or not, subject to same penalties as killing hares at that time of night, by 13 *Geo. III. c. 80.* as has been already shewn. Every person qualified to kill game, shall, previous to his shooting at, killing or destroying any game, deliver in writing his name and place of abode, if in *England*, to the clerk of the peace, if in *Scotland*, to the sheriff or steward clerk of the county where resident, and annually take out a certificate thereof, stamped with a two guinea stamp, 24 *Geo. III. sess. 2. c. 43. s. 1.* and the 31 of *Geo. III. c. 21.* an additional stamp of one guinea, making in all three guineas, and from and after the passing of this act, every such qualified person who shall so deliver in *England* or *Scotland*, his name and place of abode as aforesaid, and require a certificate thereof, shall be annually entitled thereto, stamped as aforesaid, from clerk of peace or his deputy, sheriff, or steward clerk, to the effect of the form in the act set forth, 24 *Geo. III. sess. 2. c. 43. s. 3.* Clerk of peace, &c. after he shall have signed such certificate, shall forthwith issue the same, stamped, to the person so delivering in his name and place of abode, and requiring the same, for which he shall be entitled to receive 1*s.* for his own trouble, 24 *Geo. III. sess. 2. c. 43. s. 4.* Neglect in, or refusing certificates, incurs like forfeiture, and which are recoverable in like manner, and with same costs as to gamekeepers, as before mentioned; besides liable to pay the duty on such certificate, 24 *Geo. III. sess. 2. c. 43. s. 4.*

The time for sporting in the day is, from one hour before sun-rising, until one hour after sun-setting, 10 *Geo. III. c. 19.* The sporting season for bustards is from December 1 to March 1. For grouse or red-game, from August 12 to December 10. Hares may be killed all the year, under the restriction in 10 *Geo. III. c. 19.* Heath-fowl, or black game, from August 20 to December 20, 13 *Geo. III. c. 55.* Pheasants, from October 1 to February 1. Partridges, from September 1 to February 12, 2 *Geo. III. c. 19.* Fowls, widgeons, wild-ducks, wild-geese, at any time, but in June, July, August, and September, 10 *Geo. III. c. 32.*

From and after October 1, 1784, in all cases where the penalty by this act, does not exceed 20*l.* justice of peace shall, upon information or complaint, summon the party and witnesses to appear, and proceed to hear and determine the matter in a summary way, and upon due proof by confession, or upon the oath of one witness, give judgment for the forfeiture; and issue his warrant for levying the same on offender's goods, and to sell them, if not redeemed within six days, rendering to party overplus, and if his goods be insufficient to answer the penalty, shall commit offender to prison, there to be for six calendar months, unless penalty be sooner paid; and if party be aggrieved by the judgment, he may upon giving security amounting to value of forfeiture, with the costs of assurance, appeal to the next general quarter sessions, when it is to be heard and finally determined; and in case the judgment be affirmed, sessions may award such costs incurred by appeal as to themselves shall seem meet, 24 *Geo. III. sess. 2. c. 43. s. 19.* Witnesses neglecting or refusing to appear, without reasonable excuse, to be allowed of by the justice, shall respectively forfeit, for every offence, 10*l.* to be levied and paid as other penalties by this act 24 *Geo. III. sess. 2. c. 34. s. 20.* Justice to cause conviction to be made out to the effect of the form set forth in the act 24 *Geo. III. sess. 2. c. 43. s. 21.* Justice may mitigate penalties as he thinks fit, so that

the reasonable costs and charges of officers and informers for discovery and prosecution, be always allowed, over and above mitigation, and so as same does not reduce the penalty to less than a moiety, over and above the costs and charges, 24 *Geo. III. sess. 2. c. 43. s. 22.*

It is felony to take any swans that be lawfully marked, though they be at large; and so it is unmarked swans, if they be domestical or tame, so long as they keep within a man's manor, or within his private rivers, or if they happen to escape from them, and are pursued and taken, and brought back again; but if they be abroad, and attain their natural liberty, then the property of them is lost, and so long felony cannot be committed by taking them, *Burn's Just. Tit. Game.*

Same laws against shooting wild-fowls as for shooting hares, by 1 *Jac. I. c. 27. s. 2.*

I have here also added an abstract from the late act of parliament for preventing the stealing of dogs, which shews the great regard the legislator has to the canine race.

By the statute of 10 *Geo. III.* for preventing the stealing of dogs, it is enacted, that after the 1st day of May 1770, if any person shall steal any dog or dogs of any kind or sort whatsoever, from the owner thereof, or from any person intrusted by the owner thereof with such dog or dogs; or shall sell, buy, receive, harbour, detain, or keep any dogs of any kind or sort whatsoever, knowing the same to have been stolen as aforesaid, every such person being convicted thereof upon the oath of one credible witness, before two justices of the peace, shall for the first offence forfeit and pay any sum, not exceeding 30*l.* nor less than 20*l.* and the charges of conviction. And in case such penalty shall not be forthwith paid, the offender to be committed to goal for any time not exceeding twelve months, nor less than six, or until the penalty and charges are paid. Any person guilty of a subsequent offence, to forfeit and pay any sum not exceeding 50*l.* nor less than 30*l.* together with the charges, which penalties to be paid, one moiety thereof to the informer, and the other to the poor of the parish. On non-payment, the offender to be imprisoned for any time not exceeding 18 months, nor less than 12, or until the penalty and charges shall be paid, and be publicly whipped.

Justices to grant warrants to search for dogs stolen. And in case any such dog or dogs, or their skins, shall upon such search be found, to take and restore every such dog or skin to the owner, and the persons in whose custody any such dog or skin shall be found, are liable to the like penalties and punishments. Persons aggrieved may appeal to the quarter-sessions, and the determination there to be final.

GAP, a breach or opening made in a hedge.

GARGET, or Gargol, a distemper incident to hogs; and is known by the creature's hanging down his head, and carrying it on one side, moist eyes, staggering, and loss of appetite.

It is occasioned by a corruption of the blood, engendered by the eating of rotten fruits, garbidge, carrion, or rank grass, wherein is much hemlock, &c.

In order to cure this disease, let the creatures be first blooded both under the tail and under the ears, and then the following drink given them:

Take of chamber-lye one pint; rue and southern-wood, cut small, of each a handful; wood-foot from an oven, and common salt, of each a spoonful; hen's dung, near two spoonfuls; flour of brimstone one ounce: stir the whole together, and give two or three horns to each, proportional to their size. It is also good for a cow to cure the gargol or murrain.

Or you may use the following drink in the room of the above:

Take angelica, flavewort, or hog's madder, and May-weed, of each one handful; shred them together very small, and boil them very well in a pint of milk; and when it is cold enough, add to it a penny-worth of sallad-oil, and the same quantity of treacle. *Mor-timer's Husbandry, vol. 1. p. 250.*

GARTH, a yard, a backside, a croft.

GARNER, a granary, or repository for corn.

GARZIL, hedging wood.

GASCOIN, the inner thigh of an horse, which begins at the iliac, and reaches to the pla or bending of the ham.

GAUNT

GAUNT BELLYED, OR LIGHT BELLYED HORSE, is one whose belly shrinks up towards his flank; whence you may conclude he is extremely costive, and annoyed with much unnatural heat, so as to be always very watthy, tender, and unhealthy, after hard labour.

In order to the cure of it, it must be observed, that all horses have two small strings, reaching from the cuds to the bottom of the belly, one on each side; you must therefore with your finger break these strings, and then anoint the part every day with fresh butter and the ointment *populneum* mixed to equal quantities.

GAFEL, a frame of timber upon hinges to give a passage into inclosed ground. See **HANGING GATES**.

GATEWAY, the passage through gates of inclosed grounds.

GATTERIDGE-TREE, prickwood.

GAVEL, a row, or swarth of corn, cut down with the scythe.

GAVEL, is also a provincial word, signifying ground.

GAVEL-KIND, a custom whereby the lands of the father are equally divided at his death among all his sons.

GAVELOCK, a pitch, or iron-bar for entering stakes into the ground.

GEESE, birds too well known to need any description here. They are very profitable to the farmer many ways, for their flesh, their feathers, and their grease. They will live upon commons or any sort of pastures, and need very little care or attendance; only they should have plenty of water. The largest geese are reckoned the best: but there is a sort of Spanish goose, that is a much better layer and breeder than the English, especially if the eggs are hatched under an English goose.

Geese lay in the spring, the earlier the better; because of their price, and their having a second brood. They commonly lay twelve or sixteen eggs apiece. You may know when they will lay, by their carrying straw in their mouth; and when they will sit, by their continuing on their nests after they have laid. A goose sits thirty days; but if the weather be fair and warm, they will hatch three or four days sooner. After the goslings are hatched, some keep them in the house ten or twelve days; and feed them with curds, barley meal, bran, &c. and after they have acquired some strength, let them out four or five hours a day, taking them in again till they are big enough to defend themselves from vermin. Others put them out at first, and perhaps succeed as well as the former. One gander will be sufficient for five geese.

If you would fat green geese, you must shut them up when they are about a month old, and they will be fat in about a month more. Be sure to let them have always by them, in a small rack, some fine hay, which will much hasten their fattening. But for fattening of older geese, it is commonly done when they are about six months old, in or soon after harvest, when they have been in stubble fields, from which food some kill them, which is a good way. But those who are desirous of having them very fat, shut them up for a fortnight or three weeks, and feed them with oats, split beans, barley-meal, or ground malt mixed with milk; but the best thing to fatten them with is malt mixed with beer. You must however observe in fattening all sorts of water-fowl, that they usually sit with their bills upon their rumps, where they suck out the greater part of their moisture and fatness, at a small bunch of feathers, which you will find standing upright on their rumps, and always moist, with which they trim their feathers, which renders them more oily and slippery than the feathers of other fowls, and causes the water to slip off them. If therefore these upright feathers are cut away close, they will become fat in less time, and with less meat than otherwise. Geese will likewise feed on, and fatten well with carrots cut small and given them; or if you give them rye before, or about Midsummer, it will strengthen them, and keep them in health, that being commonly their sickly time.

In some countries they shear their geese for feathers, and some pull them twice a year; but the latter is more injurious to them, and therefore it is better staying till their moulting time, and till their death, for the feathers. *Mortimer's Husbandry*, vol. I. p. 255.

Mr. Young, in his *Annals of Agriculture*, vol. xiv. speaks of the treatment of geese in Lincolnshire, to the following effect:

"It is generally allowed that three geese to one gander is sufficient, more geese would be too many so as to render the

eggs abortive. The quantity of eggs to every goose for sitting, about 12 or 13.

"They must be fed with corn in their water whilst sitting; near them, so as to feed at pleasure. The ganders should be allowed to keep near them, so that they can see them, as they will naturally watch as guard over their own geese.

"Their nests should be made for them of straw, and confined so as the eggs cannot roll out when the geese turn them, which they do every day.

"When near hatching, the shell should be broke a little against the beak, or nib, of the gosling to give air, or to enable it to receive strength, to throw off the shell at a proper time. The method of plucking them; about the beginning of April: pluck gently and carefully, the fine feathers of their breasts and backs, but be careful not to pull or interrupt their down, nor pen feathers.

"You also pull their quills, five out of a wing, but I think four would be better. The quills will bear pulling in 13 or 14 weeks again, twice in a year; the feathers three times a year, of the old geese and ganders, seven weeks from the first pulling; and then again seven weeks after, which is the last pulling of the year.

"The young geese may be pulled once at 13 or 14 weeks old, but not quilled, being hatched in March.

"If the geese are late in hatching, I expect the brood geese should not be plucked so soon as April, but the month after.

"If they are fed with barley and oats, as they ought to be, they will thrive and do the better, and their feathers will grow faster and be better in quality. They must have plenty of grass and water."

GELDING, a castrated animal. In the performing of this, three things are to be observed; first the age, then the season of the year, and lastly the state of the moon.

As to the first, if it be a colt, he may be gelded at nine days old, or fifteen, if his stones be come down; for the sooner you geld him, the better, for the growth, age, and courage; but a farrier may geld a horse at any age whatever, if he be careful of the cure.

As to the time of the year, it should be done between April and May, or in the beginning of June at farthest; or at the fall of the leaf, which is about the latter end of September.

But for the third thing, viz. the state of the moon, the fittest time is always when the moon is in the wane or decrease.

As to the manner of gelding, whether it be a foal, colt, or horse, after you have cast him upon some soft place, take the stones between your foremost finger and your great finger, then slit the cod and press the stones forth; when that is done, with a pair of small nippers made of steel, box, or brazil wood, being very smooth, clap the strings of the stones between them very near, cut to the setting on of the stones, and press them so hard, that there may be no flux of blood, then with a thin drawing cauterizing iron, made red hot, sear away the stone: after that take an hard plaister, made of rosin, wax, and washed turpentine, well dissolved together, with your hot iron, melt it upon the head of the strings; that being done, sear them, and melt more of the salve, till such time as you have had a good thickness of the salve upon the strings.

Lastly, loose the nippers, and do so to the other stone; fill the slits of the cod with white salt, anoint all the outside of the cod with hog's grease, and then let the horse rise; keeping him in a warm stable loose, that he may walk up and down, for there is nothing better for him than moderate exercise.

But if you perceive that he swells in the cod and sheath very much, walk him up and down, and make him trot an hour in a day, which will soon recover him and make him sound.

GELT-GIMMER, a barren ewe.

GEOFF, or *Goffi*, a mow of hay or corn.

GERMINATION, the act of sprouting or shooting: growth.

GERMINS, buds, tender shoots.

GIGGS, small swellings, or bladders on the inside of the lips and palate of a horse.

They are cured by slitting them open with a knife or lancet, and washing them afterwards with salt and vinegar.

GILL, a rivulet, a beck. It is also a name for ground-ivy, or hale-hoof.

GIMMER-LAMB, or *Gammer Lamb*, an ewe-lamb.

GIN.

GIN. Mr. Young, in his *Annals of Agriculture*, says, it is asserted to be a custom with some farmers, who fatten much veal, to give the calves little balls of barley-meal dipped in gin; and it is founded upon experience, that they fatten much the speedier.

GLANDERS, a very obstinate and loathsome disease incident to horses.

The cause and seat of the glanders has till lately been so imperfectly handled, and so little understood by the writers on this distemper, that it is no wonder it should be ranked among the incurables; but a new light having been thrown on this whole affair by the study of M. La Fosse, the king of France's farrier, who has been at the pains to trace out, and discover, by dissections, the source, and cause of this disorder, we hope the method he has proposed, with some further experiments and improvements will soon bring to a certainty of cure (in most cases at least) a distemper so dangerous to our horses, and that hitherto has eluded the force of art.

Before we make mention of this work which, has the approbation of the Royal Academy of Sciences, it will not be unacceptable to our readers, we apprehend, to have a more particular account of the symptoms of this disorder from M. La Fosse, that we may the better judge of the merit of our author and his discoveries.

This gentleman then has distinguished seven different kinds of glanders, four of which are incurable.

The first proceeds from ulcerated lungs, the purulent matter of which comes up the trachea, and is discharged through the nostrils, like a whitish liquor, sometimes appearing in lumps and grumes. In this disorder, though the matter is discharged from the nostrils, yet the malady is solely in the lungs.

The second is a wasting humour, which usually seizes horses at the decline of a disease, caused by too hard labour; this defluxion also proceeds from the lungs.

The third is a malignant discharge, which attends the strangles sometimes, and falls upon the lungs, which runs off by the nostrils.

The fourth is, when an acrimonious humour in the farcy seizes these parts, where it soon makes terrible havoc.

The fifth kind we shall describe by and by, as arising from taking cold.

The sixth kind is a discharge from the strangles, which sometime vents itself at the nostrils.

These are the various disorders which have been observed sometimes to throw matter out from the nostrils; let us now describe the real glanders:

The matter then discharged from the nostrils of a glandered horse, is either white, yellow, or greenish, sometimes streaked, or tinged with blood; when the disease is of long standing, and the bones are fouled, the matter turns blackish, and becomes very foetid; and is always attended with a swelling of the kernels or glands under the jaws: in every other respect the horse is generally healthy and sound, till the distemper has been of some continuance.

It is always a bad sign, when the matter sticks to the inside of the nostrils, like glue or stiff paste; when the inside of the nose is raw and looks of a livid, or lead colour, when the matter becomes bloody, and stinks, and when it looks of an ash-colour. But when only a limpid fluid is first discharged, and afterwards a whitish matter, the gland under the jaw not increasing, and the disorder of no long continuance, we may expect a speedy cure; or in this case, which arises from taking cold, after a horse has been over-heated, the pituitary membrane is but slightly inflamed, the lymph in the small vessels condensed, and the gland overloaded, but not yet ulcerated.

From these symptoms and some observations made both by Bracken and Gibson, it is plain they were not absolute strangers to the seat of this disorder, though they neglected pushing their inquiries to the fountain-head, and consequently were at a loss to know how to apply the remedy to the parts affected.

But our author, after examining by dissection the carcasses of glandered horses, and making a strict scrutiny into the state of the viscera, assisted for that purpose by ingenious and expert anatomists for ten years together, affirms this disease to be altogether local; and that the true seat of it is in the pituitary membrane, which lines the partition along the inside of the nose, the maxillary sinusses or cavities of the cheek-bones on each side the nose, and the frontal sinusses or cavities above the orbits of the eyes;

that the viscera, as liver, lungs, &c. of glandered horses are in general exceeding sound: and consequently that the seat of this disorder is not in those parts, as has been asserted by most authors; nor indeed is it probable it should: for how could such horses preserve their appetite, their good appearance, sleek and shining coats; in a word, all the signs of health for many years together (which many glandered horses are known to enjoy) with such distempered bowels.

But on nicely examining the heads of such horses, he found the cavities above-mentioned, more or less, filled with a viscous slimy matter, the membrane, which lines both them and the nostrils inflamed, thickened, and corroded with sordid ulcers, which in some cases had eat into the bones. These sinusses or cavities will be better understood by referring to the annexed plate.

He observes, that when glandered horses discharge matter from both nostrils, both sides of the membrane and cavities were affected; but when they ran at one nostril only, that side only was found distempered.

It is a curious remark of our author, that the sublingual glands, or the kernels situated under the jaw-bone, which are always swelled in this distemper, do not discharge their lymph into the mouth, as in man, but into the nostrils; and that he constantly found their obstruction agreed with the discharge; if one gland only was affected, then the horse discharge from one nostril only; but if both were, then the discharge was from both.

He sometimes, though rarely, found the boney partition of the nose carious or rotten; but that the spongy bones about this part must suffer from the acrimony of matter long pent, is not at all to be doubted, though the more solid ones may escape.

The seat of this disorder thus discovered, our author, with great ingenuity, has paved the way for cure, by trepanning these cavities, and taking out a piece of bone, by which means the parts affected may be washed with a proper injection: and, in fine, the ulcers deterged, healed, and dried up.

But as from the observations since made by this gentleman, there are different species of the glanders, so the cure of the milder kinds may first be attempted by injections and fumigations. Thus, after taking cold, should a horse for fifteen or twenty days discharge a limpid fluid, or whitish matter from one or both nostrils, the glands under the jaw rather growing harder than diminishing, we may expect it will degenerate into true glanders: to prevent which, after first bleeding, and treating him as we have directed for a cold, let an emollient injection, prepared with a decoction of linseed, marshmallows, elder, chamomile flowers, and honey of roses, or such like, be thrown up as far as possible with a strong syringe, and repeated three times a day: should the running not lessen, or be removed in a fortnight by the use of this injection, a restraining one may now be prepared with tincture of roses, lime-water, &c. and the nostrils fumigated with the powders of frankincense, mastich, amber, and cinnabar, burnt on an iron heated for that purpose, the fume of which may easily be conveyed through a tube into the nostrils.

This method has been found successful when used in time; but the methods of cure depend on the stubbornness of the disorder; and, when inveterate, recourse must be had to the operation above described.

This operation he has performed on three horses, two of whom discharged from one nostril only, and the third from both; the two first he trepanned on that side of the head which was affected, and to the other he performed it on both, and found that the wound and perforation filled up with good flesh in twenty-six days, and the horses suffered no inconvenience from the operation; though after this experiment they were put to death.

The directions and orders of the civil government of France, which hindered people from keeping glandered horses, long prevented M. La Fosse repeating his attempts, and pushing his experiments further; but it is to be hoped that so useful a project will be pursued to its utmost extent, as it seems so promising in the execution, and is so important in its consequences: to which end we shall beg leave to animadvert on what has been said, and offer our opinion both in relation to the disease, the operation, and the manner in conducting the cure.

In order to prove that a great inflammation of the pituitary membrane is always the cause of the glanders, M. La Fosse has attempted to bring on an inflammation upon the

the same membrane, by a corrosive injection; and when the injection was only thrown into one side, the maxillary lymphatic glands were swelled on the same side, and that nostril only produced the discharge; but when both nostrils were injected, these symptoms appeared on both sides. This gentleman has also observed, that the bone of the maxillary sinus being broke by the kick of another horse, the usual symptoms of the glanders soon appeared, from the inflammation the pituitary membrane suffered on the occasion.

The original source and cause then of this disorder seems to be an inflammation in the glands and membrane that lines the nostrils and these cavities, which, if not dispersed in time, will form matter, that will ulcerate and erode the bones, for want of a free discharge to unload the cavities, and of proper applications to cleanse and deterge the ulcers: violent cold, or a feverish translocation settling here, may also occasion the same complaint, and are probably the general causes.

There is a disorder in men called *Ozæna*, that has great similitude to this in horses, and arises from an inflammation in the maxillary sinusses, or cavities in the cheek-bones, from whence ensues a collection of matter, which, when the cavity is full, or the head properly inclined, runs over into the nose, and would constantly discharge thence like a glandered horse, was the head continued in the same position. The surgical cure is the taking out one or more teeth from the upper jaw, and perforating the cavity with a proper instrument, in order to make a depending orifice for the matter to flow through; and to make way for syringing the parts effected with proper injections which in this case are thrown through the cavity into the nose.

The similarity of these two cases, with the method of cure, and the success attending the surgical treatment (which was first invented and perfected by our countrymen Drake and Cowper) undoubtedly gave the first hint for trepanning, and syringing these cavities in horses; and it is most probable, that when the operation is attempted in time, before the bones become rotten, it will be attended with equal success; but after opening the cavities, should it by probing be discovered, that the bones are in that state, the best way then would be to dispatch the horse, to prevent unnecessary trouble and expence.

The parts fixed on for applying the trepan are pointed out in the plate, and the manner of sawing out the bone will easily be understood by a view of the instrument, and the explanation annexed.

The perforations being made, our next business is to prevent their filling up too fast, as it may be necessary to keep them open for some weeks before a cure can be effected; for which purpose, after the use of the injections, let the upper one be filled up with a piece of cork, waxed over, and adapted exactly to its size, the lower one may be kept open with a hollow leaden tent, through which there will be a constant drain of matter from the sinusses, which will be greatly favoured by this depending orifice, and both be detained by a proper bandage.

If this method should not prevent the granulations, or shoots of the flesh, from filling up so fast as to choak up the perforation, and by that means hinder the injections passing freely, they must be suppressed by rubbing with caustic medicines, or touching with the actual cautery; as may also the bony edges, which, by obliging them to exfoliate or scale off, will retard the healing.

The injection first made use of, should be of a deterfive nature; as a decoction of birth-wort, gentian, and centaury; to a quart of which, if two ounces of *Egyptiacum* and tincture of myrrh are added, it may be as proper as any; and when the discharge is observed to abate, and the colour alter to a thick white matter, the injection may be changed for barley-water, honey of roses, and tincture of myrrh; and, finally, to dry up the humidities, and recover the tone of the relaxed glands, Bate's allum-water, or a solution of calcothar, vitriol, lapis medicamentosus, or such like, in lime-water, will most probably complete the cure. Dr. Bracken recommends the following:

Take of allum and white vitriol powdered, of each four ounces; calcine them in a crucible when cold, powder the calx, and mix it with a gallon of lime-water and a quart of vinegar; decant the clear for use.

But whoever is at all acquainted with practical surgery, well knows, that without the assistance of internals, especially in glandular disorders, the cure is not so easily effected, nor rendered complete or lasting: we therefore advise a strong decoction of guaiacum chips to be given every day, to a quart or three pints, throughout the cure, and when the matter lessens, to purge at proper intervals, and put a rowel into the horse's chest, in order to divert the fluids from their old channel: if these should not succeed, mercurials may be given with the phytic, and the alterative powders with lime-water may be taken for a time, if the horse is worth the expence.

An explanation of the Heads and Trepan. See Plate XVII. Fig. 2.

B. B. two lines representing the bounds of the cerebellum, or back part of the brain, which is very small in a horse, in proportion to that of a man, as well as the brain itself, which commences from the line D.

C. C. a line where the superior part of the sinus frontalis commences, together with a view of the bottom of the sinus, which terminates between the lines D and E, where there appears a substance in the form of a pear, which is the *os ethmoides*, or sieve-like bone, through which the olfactory nerves pass, by which the pituitary membrane receives its sensibility, and the sense of smelling is performed.

E. represents the beginning of the maxillary sinus, which terminates at M.

The shaded space, which may be observed between these two lines, represents the great cavities. The oblique ray marked F, is a bony partition, which separates this sinus into two parts, that have no communication; and sometimes it happens (though but rarely) that there are two bony partitions; and for this reason they are represented by the lines marked F and G. It also sometimes happens (but still more seldom) that there are horses, in whose heads we do not find any of these bony partitions.

N. points out the place of the cornets or horns. O, the redoublings. F, their middle part. Q, the inferior part of them. M, the bony canal or pipe which guards the maxillary nerve.

A. A. the septum narium, or partition, which divides the nose from top to bottom, and constitutes the two nostrils.

L, in the head that is intire, points out where the trepan should be applied on the frontal sinus, when we have reason to believe the glanders is spread into this sinus. However, I think it safest to apply it first on E, for the reasons mentioned in the next explanation, and because the brain may be endangered, should the sinus be mistook.

E, the place where the trepan may be applied, in order to cleanse the maxillary sinus. The round mark between D and E (which is the impression of the trepan) is, however, on experience, preferred by the author, as the properest place, as one orifice would then be sufficient to wash all the parts, both above and below, with the injection.

But in general, when the maxillary sinus is only affected, penetrate but the upper part, where the syringe points, or thereabouts, and your expectations will be answered; should they not, there seems so little danger in the operation, that you may again perforate at the places above-mentioned, higher up. But a proper number of experiments will soon settle this point with certainty.

H, in the head that is intire, points out the place where another hole, or perforation should be made, as a drain to give issue to the glanderous matter washed away by the injection which could not be discharged without such a depending orifice; and perhaps this perforation alone, in many recent cases, would be sufficient, provided the injection passed freely upwards, and the hole was kept open by means of a hollow leaden pipe constantly retained in it for that purpose, and to procure a free passage for the matter.

I, represents the injection pushed in by the syringe, which flows out by the orifice and the nostril K; during the use of the syringe, it is necessary to hold the nostrils close.

If, in the maxillary sinus, instead of one there happens to be two bony partitions, it is absolutely necessary to

pierce through them both, by means of a filetto, or sharp-pointed tuck, as in the manner represented in the cut of a horse's head opened, though this conformation seldom occurs.

As these bony partitions may in some particulars vary, should the filetto not have the desired effect, and the injection thrown in by the syringe not come out at H; in such case the liquor should be injected upwards, through the orifice made by the filetto or trepan at H.

As in young horses the frontal and maxillary sinusses are very small, it will be proper to direct the trepan towards the interior part of the nose, otherwise the instrument might work upon the roots of the teeth, which incline towards the sinus, and would in such case be an insurmountable obstacle to the operation.

R, the instrument or trepan. S, the handle which turns it. T, the saw-part to be applied to the bone.

From a view of this instrument, the manner of working it will appear simple and easy; the cooper's managing his wimble being a proper directory.

The instrument called the trephine, which is chiefly used by our English surgeons in perforating the skull, will equally answer this purpose; and if any difficulties should arise, notwithstanding this description, the gentlemen of the faculty will soon make it familiar and intelligible.

Before the application of the trepan, or trephine, it is quite necessary to observe, that a circular piece of the skin should first be cut off, with the membrane which covers the bone, about the size of a half-crown-piece, in order to make the instrument work the easier, and to prevent the inconveniencies which might arise from the external wounds healing up too fast.

The syringe should be large enough to contain half a pint of injection.

GLANDIFEROUS, an epithet applied to such trees as bear mast or acorns. Thus the oak, beech, &c. are called glandiferous trees.

GLEANNING, the action of picking up the ears of corn left behind by the gatherers.

GLEBE, properly signifies the soil or ground in general; but is particularly applied to the land possessed as part of the revenue of an ecclesiastical benefice.

GLEBOUS, or *gleby*, turfy.

GLEDE, a kite.

GLEN, a valley, a dale.

GLYSTER, or *Clyster*, a medicine injected into the anus of an animal.

Glysters are often necessary for horses in various disorders, and may be reduced to these different kinds, viz. laxative and emollient, purgative and restraining.

But it should be observed, that before the administration of emollient glysters in costive disorders, a small hand well oiled should be passed up the horse's fundament, in order to bring away any hardened dung, which otherwise would be an obstacle to the clyster's passage.

A bag and a pipe of a proper form, is to be preferred to a syringe, which throws up the clyster with so much force, that it often surprises a horse, and makes him reject it as fast as it goes in: whereas the liquor, when pressed gently from the bag, gives him no surprize or uneasiness, but passes up easily into the bowels, where it sometimes remains a long time, and is extremely useful, by cooling and relaxing them; and will sometimes incorporate so with the dung, as not easily to be distinguished from the other contents of the guts. These emollient clysters are extremely serviceable in most fevers, and greatly preferable to purging ones; which in general are too pungent, and stimulate too much, especially if aloes are a part of the composition.

Nutritive clysters are very necessary, and often save a horse from starving, when his jaws are so locked by convulsions, that nothing can be conveyed by the mouth.

They should not exceed a quart or three pints at a time, but be often repeated: nor should they be too fat; but made of sheeps-heads, trotters, or any other meat-broths, milk-pottage, rice-milk strained, and many other such nourishing things. For an emollient clyster take the following:

Take marshmallows and camomile flowers, each a large handful; bay-berries and sweet fennel-seeds bruised, each an ounce, boil in a gallon of water to three quarts, pour off into a pan, and dissolve in it

half a pound of treacle, and a pint of linseed oil, or any common oil.

To make it more laxative, add four ounces of lenitive electuary, or the same quantity of cream of tartar, or common purging salts.

Take two or three handfuls of marshmallows, fenna one ounce, bitter-apple half an ounce, bay-berries and aniseed bruised, each an ounce, salt of tartar half an ounce; boil a quarter of an hour in three quarts of water, pour off, and add four ounces of syrup of buckthorn, and half a pint of oil.

This clyster will purge a horse pretty briskly; and may be given successfully, when an immediate discharge is wanting; especially in some fevers with inflamed lungs, or other disorders, which require speedy relief.

But it is necessary to caution against a solution of coarse aloes for this purpose, as it has been found to gripe horses violently, and excite feverish, and sometimes convulsive symptoms; and indeed all pungent and stimulating medicines, as the stronger purgatives generally are, should be given in this form with great caution.

But the generality of emollient clysters may be prepared with much less trouble; as two quarts of water-gruel, with half a pound of treacle, a pint of oil, and a handful of common salt, will as effectually answer every purpose. The following is a restraining clyster.

Take pomegranate-bark, or oak-bark, two ounces; red rose-leaves, fresh or dry, a handful; balustines, an ounce; boil these in two quarts of water, till one is nearly consumed; then pour it off, and dissolve in it four ounces of diascordium; to which may be added a pint of Port-wine.

This will answer all common cases, where restraints are necessary, but should never be given in larger quantities; for the longer clysters of this kind lie in the bowels, the more efficacious they are. *Bartlet's Farriery*, p. 22.

Take of chamomile-flowers, sweet fennel, and coriander-seeds bruised, of each one ounce; caraway-seeds half an ounce; boil in two quarts of water, till reduced to three pints; then strain, and add for solution, while hot, of Epsom salts two ounces; and, when nearly cool enough to administer, add of olive-oil and tincture of fenna, commonly called Daffy's Elixir, of each a quarter of a pint.

GNATS, are troublesome to those who live near watery places, and they likewise destroy the leaves and vegetables as soon as they appear, especially turneps; to remedy which, burnt straw or dried fern will drive them away. To clear the house of them, the smoke of tobacco will effectually answer, when by closing our doors and windows they cannot re-enter. They are easily attracted by ash-leaves hung up in a room, or balls made of new horse-dung, so that you may cover them with a basin and destroy them.

GOAD, a pointed instrument with which oxen are driven forward.

GOAR-VETCHES, the same with summer-vetches. See the article VETCHES.

GOAT, a genus of animals, the characters of which, according to Mr. Ray, are these; that it is covered with hair, not with wool; that its horns are less crooked than those of a sheep, and that it has a beard hanging down from its chin, and is of a strong smell.

It is very singular that this genus of animals are all able to run and climb about the rugged parts of mountains without falling, though their feet seem by no means contrived by nature for any such purposes.

Goats may be of great advantage to the farmers in some parts of the kingdom, as they will live in rocky barren countries, where nothing else can get a support for life. They will climb the steepest rocks, and there browse upon briars, heath, and shrubs of various kinds, which other creatures will not taste of. They will feed on grass in pastures; but, as they love browsing on trees much better, great care must be taken to keep them from valuable plantations.

The greatest advantage of these creatures is their milk, which

which they yield in large quantities: and which is accounted the best milk of all animals. They mix this and cows milk together in many parts of the kingdom, and a very valuable kind of cheese is made of it. Beside this, the kids or young goats are very fine food, and the best kinds bring forth these two or three at a time, and that twice a year.

Goats hair also is valuable; it may be sheared as the wool from sheep, and is excellent for making ropes that are to be used in the water, as they will last a great while longer than those made the common way. A sort of stuff is also made of it in some places. The best kind of goats for keeping to advantage should be chosen in this manner: the male should have a large body, his hair should be long, and his legs straight and stiff; the neck should be plain and short, the head small and slender, the horns large, the eyes prominent, and the beard long. The female should have a large udder, with large teats, and no horns, or very small ones. They should be kept in flocks, that they may not straggle; and they should have good shelter both in summer and in winter, the heat and cold being both prejudicial to them. They should be coupled in December. They should have no litter in winter, but only a paved floor kept clean. The kids are to be brought up for the table in the same manner as our lambs are. They are recommended to lie among horses, their smell, as supposed, preventing many distempers in those cattle. *Mortimer's Husbandry*, vol. I. p. 244.

GOAT, the utility of. See STAGGERS.

GOD's-GOOD, yeast, or barm.

GOFFE, the same with geoff. See GEOFF.

GOOL, a ditch.

GOOSE. See the article GESE.

GOOSE-GRASS, or wild tanfy, the name of a troublesome weed very frequent in clay-grounds. The best method of destroying it is to mow it in summer, well dung the land, and never plough it out of heart.

GOSS, or *Gorse*, the furze.

GOULANS, corn-marigolds.

GOURDY-LEGS. A distemper in horses, caused by pains and other fleshy sores.

The way to cure them, is first to shave away the hair upon and about the sore place, as close as may be, and then to anoint it with linseed oil and aqua vitæ, shaken together till they are perfectly mixt; and renew the mixing of it as often as you have occasion to use it, because they will separate by standing, without being shaken; anoint the sore place with this every day till the sore be made whole.

GRAIN, a general name for all sorts of corn, as wheat, barley, &c.

GRAINS. See FATTENING CATTLE.

GRANARY, a building to lay or store corn in, especially that designed to be kept a considerable time

Experimental philosophy has proved, that the air is the great source of corruption; keep out that, and all is kept out; and the most corruptible substances, such as meal, butter, milk, and the like, have been preserved fresh four months in the exhausted receiver of an air-pump.

They have near Grand Cairo, a magazine or granary, defended with good walls, and called Joseph's granaries. It is not probable that they are quite so old as the days of that patriarch; but they abundantly prove the utility of such store-houses, by the vast quantities of grain annually preserved in them.

Many parts of Africa abound with granaries of this kind.

They are so many deep pits made in the solid rock; the descent into them is but just large enough for a man to go down into them; but they grow larger as soon as the person is in, and are usually square, from thirty to forty feet in diameter. In these the great men of the country preserve their corn; they first strew over the floor with straw, then they lay on the corn, till as the heap rises, placing a thin bed of straw between the corn and the sides, as they did at the bottom. In this manner they proceed till the whole cavity is filled: when this is done, they cover the mouth of the entrance with a sort of hurdle of green boughs of trees, interwoven one with another. This they cover with about two feet thickness of sand, and over this raise a ridge of earth, well beat together, in order to throw off the rain both ways, that none may settle on the place and soak into the magazine.

The corn thus stored up always keeps three, four, or more years very good; and, not unfrequently, the pro-

prietor being taken off by the severity of the eastern governments, under which they live, the magazine is forgotten, and some accident discovering it many years afterwards, the corn is almost always found perfectly good in it. All the care they take, in regard to the corn, is to expose it two or three days to the sun's heat, to dry it, thoroughly, before they carry it into a magazine.

In the dutchy of Lithuania, and in the Ukraine, the people always preserve their corn in the same manner in wells or pits made in dry places: but in these countries great care is to be taken in the opening these store-rooms; for if people descend into them before they have had sufficient communication with the fresh air, they are often killed by the damps; this, however, is easily guarded against. By these, and numerous other instances of the practice of other countries, it appears evident, that the advantage of these subterranean granaries over all others is very great.

Though these are to be recommended before all others; yet the common granaries may, with proper care, be rendered greatly more useful than they are at present. The grand caution necessary to this purpose is, to guard against the too great humidity, which there always is in places where there is a great number of doors and windows. A too free access of the external air is also to be carefully guarded against; for this brings in with it the eggs of a vast number of different insects, which prey upon, and destroy the corn. A third caution is, when the corn is the produce of the country where it is preserved, not to fill the place with the crop of one place only, but to mix the harvests of two as different provinces as may be, the one dry, the other moist, or otherwise differing as much as may be; thus the contrary qualities of the one will prevent the destruction of the other. These are the three great rules to prevent the corrupting of corn; but when the mischief is once begun, it will prove very difficult to stop it; all the care that can be employed, should therefore be taken in regard to these.

The two great cautions to be observed in the erecting of granaries, are to make them sufficiently strong, and to expose them to the most drying winds. The ordering of the corn in many parts of England is thus: to separate it from dust and other impurities after it is threshed, they toss it with shovels from one end to the other of a long and large room; the lighter substances fall down in the middle of the room, and the corn only is carried from side to side, or end to end of it. After this they screen the corn, and then bring it into granaries, it is spread about half a foot thick, and turned from time to time about twice in a week; once a week they also repeat the screening it. This sort of management they continue two months, and after that they lay it a foot thick for two months more, and in this time they turn it once a week, or twice, if the season be damp, and now and then screen it again. After about five or six months, they raise it to five or six feet thickness in the heaps, and then they turn it once or twice in a month, and screen it now and then. When it has lain two years, or more, they turn it once in two months, and screen it once a quarter, and, how long soever it is kept, the oftener the turning and screening is repeated, the better the grain will be found to keep.

It is proper to leave an area of a yard wide on every side the heap of corn, and other empty spaces, into which they turn and toss the corn, as often as they find occasion. In Kent they make two square holes at each end of the floor, and one round in the middle, by means of which they throw the corn out of the upper into the lower rooms, and so up again, to turn and air it the better. Their screens are made with two partitions, to separate the dust from the corn which falls into a bag: and when sufficiently full, this is thrown away, the pure and good corn remaining behind.

Corn has, by these means, been kept in our granaries thirty years; it is observed, that the longer it is kept, the more flour it yields in proportion to the corn, and the purer and whiter the bread is, the superfluous humidity only evaporating in the keeping. At Zurich, in Switzerland, they keep corn eighty years or longer, by the same sorts of methods.

The public granaries at Dantzick are seven, eight, or nine stories high, having a funnel in the midst of every floor, to let down the corn from one to another. They are built so securely, that though every way surrounded with water, the corn contracts no damp, and the vessels have the convenience

nience of coming up to the walls for their lading. The Russians preserve their corn in subterranean granaries, of the figure of a sugar-loaf, wide below, and narrow at top: the sides are well plastered, and the top covered with stones. They are very careful to have the corn well dried before it is laid into these store-houses, and often dry it by means of ovens, their summer dry weather being too short to effect it sufficiently.

GRANGE, a house or farm furnished with granaries and barns for holding corn, stables for horses, stalls for cattle, &c.

GRANIFEROUS *Pods*, are such as contain small seeds resembling grain.

GRANIVOROUS, an epithet given to animals that feed on corn or feed.

GRASS, a general name for most of the herbaceous plants used in feeding cattle.

The best season for sowing grass-seed is the latter end of August, and the beginning of September, that the grass may be well rooted before the frost sets in, which is apt to turn the plants out of the ground, when they are not well rooted. This seed should be sown in moist weather, or when there is a prospect of showers, which will soon bring the grass up; for, the earth being at that season warm, the moisture will cause the seed to vegetate in a few days: but, where this cannot be performed in autumn, the seeds may be sown in the spring; towards the middle of March will be a good time, if the season proves favourable.

The land on which grass-seed is intended to be sown, should be well ploughed, and cleared from the roots of noxious weeds, such as couch-grass, fern, rushes, heath, gorse, broom, rest-harrow, &c. which, if left in the ground, will soon get the better of the grass, and over-run the land. Therefore, in such places where either of these weeds abound, it will be a good method to plough up the surface in April, and let it lie some time to dry; then lay it in small heaps, and burn it. The ashes so produced, when spread on land, will be a good manure for it. The method of burning the land is particularly useful; especially, if it is a cold stiff soil; but where couch-grass, fern, or rest-harrow, is in plenty, whose roots run far under ground, the land must be ploughed two or three times pretty deep in dry weather, and the roots carefully harrowed off each ploughing; which is the most sure method to destroy them. Where the land is very low, and of a stiff clayey nature, which holds water in winter, it will be of singular service to make some under-ground drains to carry off the wet; which if detained too long on the grounds, will render the grass sour. The method of making these drains is prescribed under the article DRAINING.

Before the seed is sown, the surface of the ground should be made level and fine, otherwise the seed will be buried unequal. The quantity of grass-seed for an acre of land is usually three bushels, if the seed is clean, otherwise there must be a much greater quantity allowed; when the seed is sown, it must be gently harrowed in, and the ground rolled with a wooden roller; which will make the surface even, and prevent the seeds from being blown in patches. When the grass comes up, if there should be any bare spots, where the seed has not grown, they may be sown again, and the ground rolled, which will fix the seeds; and the first kindly showers will bring up the grass, and make it very thick.

Some people mix clover and rye-grass together, allowing ten pounds of clover, and one bushel of rye-grass, to an acre: but this is only to be done where the land is designed to remain but three or four years, in pasture, because neither of these kinds are of long duration; so that, where the land is designed to be laid down for many years, it will be proper to sow with the grass-seed some white trefoil, or Dutch clover; which is an abiding plant, and spreads close on the surface of the ground, sending forth roots at every joint; and makes the closest sward of any, and is the sweetest feed for cattle: so that, whenever land is laid down to pasture, there should always be six or eight pounds of this seed sown upon each acre.

The following spring, if there should be any thistles, ragwort, or such other troublesome weeds, come up among the grass, they should carefully be cut up with a spaddle before they grow large; and this should be repeated two or three times in the summer, which will effectually destroy them; for, if these plants are suffered to ripen their seeds, they will be blown all over the ground; their seeds having

down adhering to them, which assists their transporation; so that they are often carried by the wind to a great distance, and thereby become very troublesome weeds to the grass. For want of this care, how many pastures may be seen almost over-run with these weeds, especially the ragwort; when a small expence, if applied in time, would have intirely extirpated them! for a man may go over several acres of land in one day with a spaddle, and cut up the weeds just below the surface of the ground, turning their roots upwards; which if done in dry weather, they will soon decay; but this must always be performed before the plants come to have their seeds formed; because after that many sorts will live long enough to nourish their seeds after they are cut, so as to ripen them: and there will be a supply of weeds for some years after, which cannot be extirpated without a much greater expence.

The proper management of pasture land is the least understood of any part of agriculture: the farmers never have attended to this, being more inclined to the plough; though the profit attending that has not of late years been so great as to encourage them in that part of husbandry: but these people never think of laying down land for pasture, to continue longer than three years: at the end of which time they plough it up again, to sow it with grain.

Their usual method is to sow rye-grass and trefoil with barley, when they intend to lay down the ground; or sometimes sow only clover with the barley; nor is it possible to convince these people of their error in sowing corn with this grass; which they affirm to be useful in shading the grass, not considering how much the corn draws away the nourishment from the grass: but it is in vain to write to these people, who are not to be convinced, either by argument or experiment; so much are they led by custom, as not to be easily driven out of their own methods; but, as their practice of husbandry has greatly lessened the circumstances of the farmers, so that the lands are daily falling into the hands of the owners, therefore this part of husbandry should by them be principally attended to, as it may be carried on with much less expence: for pasture land requires but few hands to manage; whereas the sowing of corn is attended with great expence, and the profit is very precarious: but when this is attended with success, and the grain at a moderate price, if the whole labour is to be paid for, there will be little coming to the owner for rent, when the balance is fairly stated; but in this most gentlemen deceive themselves, and often suppose they gain by farming, when, perhaps, the whole rent of the land is lost: therefore to avoid the trouble which attends this sort of husbandry, it will be the best method to turn as much of their land into pasture as they can; which, by grazing and feeding sheep, will be attended with little expence, and a sure profit.

It is not uncommon for the husbandman, for want of distinguishing grasses for seed, to fill his ground with either weeds or bad and imperfect grasses. Whereas by making a proper choice, he would always have the best grass, and in the greatest abundance his land will admit of.

In the common way of proceeding, if a farmer wants to lay down his land to grass, he either takes his seeds indiscriminately from his own foul hay-rick, or sends to his neighbour for a supply. By this means, besides a certain mixture of rubbish, which must necessarily happen; it is not unlikely but that what he intends for dry land may have come from moist, where it grew naturally, and so on the contrary: and the consequence of this slovenly method frequently is, that the ground, instead of being covered in one year with a good sward, is filled with weeds not natural to it, which would never have sprung up, if they had not been brought thither.

"Arguments, says Mr. Stillingfleet, are never wanting in support of ancient customs, and I am no stranger to those, such as they are, which prejudice and indolence have made use of on this occasion.

"1. Some say then, that if you manure your ground properly, good grasses will come of themselves. I own they will. But the question is, how long it will be before that happens: and why be at the expence of sowing what you must afterwards try to kill? which must be the case, so long as people sow all kinds of rubbish under the name of hay-seeds. Again, if the best way is to let the ground take its chance, why is the farmer at the expence of procuring the seeds of the white and broad clover, which com-

up in almost all parts of England spontaneously? But if this is allowed not to be the best way in relation to clover of any kind, what reason can be in nature, why grass-seeds only ought not to be sown pure?

"2. Others say, that it is better to have a mixture of different seeds. I will suppose this to be true. But cannot a mixture be had though the seeds be gathered, and separated? and is not a mixture by choice more likely to be proper, than one by one chance; especially after a sufficient experience has been had of the particular virtues of each sort, of the different kinds of cattle which each grass is most adapted to, of the different grounds where they will thrive best, &c. all which circumstances are now, in general, wholly unknown, though of the utmost consequence?

"3. It is said by some, that weeds will come up along with the grass. No doubt of it. Can any one imagine, that grass-seeds should be exempted from what happens to every other kind of seeds? But I will venture to say, that not near the quantity of weeds will spring up which they imagine, if the grass be sown very thick. Men must be very much put to it, when they make such objections as this last, or indeed any of the others. I am almost inclined to say with a great writer, 'It is a simple thing to take much pains to answer simple objections.'

"One would hardly think it possible, that the slovenly method of proceeding, here complained of, could prevail universally: yet this is the case as to all grasses, except the darnel (or rye) grass, and what is known in some few countries by the name of the Suffolk-grass; and this latter instance is owing, I believe, more to the soil than to any care of the husbandmen. Now, would the farmer be at the pains of separating, once in his life, half a pint, or a pint, of the different kinds of grass-seeds, and take care to sow them separately, in a very little time he would have wherewithal to stock his farm properly, according to the nature of each soil, and might at the same time spread these seeds properly over the nation, by supplying the feed-shops.

"I have had frequent experience how easy it is to gather the seeds of grasses, having several times employed children of ten or eleven years old, who have gathered many sorts for me without making any mistakes, after I had once shew them the sorts I wanted.

"I have procured thus the creeping bent, the fine bent, the sheep's fescue, the crested dog-tail, &c. in sufficient quantities, to begin a stock; but, for want of a proper opportunity of cultivating them myself, or meeting with any one who had zeal enough to bestow a proper care on them, my collections of this kind hitherto have only proved, that the scheme is in itself feasible.

"In the year 1761, a little boy gathered, by my directions, as much of the crested dog-tail, in three hours, by the side of a road, as, when shed; yielded, upon weighing, above a quarter of a pound avoirdupois, perfectly free from husks. As this seed is small, the skilful will easily judge how far such a quantity would go if properly employed.

"My very estimable and ingenious friend Mr. Aldworth, who was witness of the fact which I last mentioned, at my desire, ordered a small part of a meadow, near his seat at Stanlake, which had better grasses, and less mixed, than the rest, to be left unmowed till the seeds were fit for gathering. This piece yielded, upon threshing and sifting, a full bushel by measure, of almost pure seed of crested dog-tail.

"In case any one should be inclined to follow this example, I think it highly necessary to observe, that care must be taken to mow the grass before it sheds; that it be mowed very early in the morning, before the dew is off the ground, and that it ought not to be spread as in making hay, but left as it falls from the scythe during a sufficient time, and then be gently turned over.

"The number of grasses fit for the farmer is, I believe, very small; perhaps half a dozen, or half a score, are all he need to cultivate; and how small the trouble would be of collecting the seeds of these, and how great the benefit, must be obvious to every one at first sight. Would not any one be looked upon as wild, who should sow wheat, barley, oats, rye, pease, beans, vetches, buck-wheat, turneps, and weeds of all sorts together? Yet how is it much less absurd to do what is equivalent in relation to grasses? does it not import the farmer to have good hay and grass in plenty? and will cattle thrive equally on all sorts of food? We know the contrary. Horses will scarcely eat hay that will do well enough for oxen and cows. Sheep

are particularly fond of one sort of grass, and fatten upon it faster than any other in Sweden, if we believe Linnæus. And may they not do the same in England? How shall we know till we have tried? Nor can we say, that what is valuable in Sweden, may be inferior to many other grasses in England, since it appears by the Flora Suecica, that they have all the good ones that we have. But however this may be, I should rather choose to make experiments than conjectures."

The Society for promoting Agriculture, &c. in the province of Britany, had laid down the most rational plan yet formed by any body of men, nobly associated for the welfare of their country, and which promises the greatest advantages to mankind. A part of this plan is the cultivating separately most of the plants which grow naturally in the fields there, in order to know which of them will afford the most and the best food for cattle.

As the husbandman would not be benefited by knowing the particular classes, genera, &c. under which Ray, Linnæus, and other botanists have ranged the several species of grasses, we shall here give the names of such of them as may be cultivated to most advantage in this country, with the best drawings (for which we are indebted to Mr. Stillingfleet) for some of the most profitable sorts, which it will be of service to the farmer to be able to distinguish rightly.

The common dogs-grass, quich-grass, or couch-grass, (*Gramen spica triticea repens vulgare, caninum dictum*) common creeping-grass, with a spike like wheat, called dogs-grass, will thrive in almost any soil, and can scarcely be got out again, after it has once taken possession: so greatly does it multiply by its roots and trailing branches, which put forth roots and shoots at every joint. It grows to the height of four or five feet, with blades so rough and coarse, that few horses will eat them, especially while they are green: but it yields abundant crops of hay, which does well enough for oxen, and therefore deserves, perhaps, more attention than our farmers have yet bestowed upon it. M. Duhamel indicates the best way of making the most of it, when he directs the farmer always to mow it before its seeds ripen, or stalks grow hard; for after that cattle refuse it; adding, that it soon shoots up again, and will bear frequent cutting.

This plant is well known to all husbandmen to whom it is a sad plague, when it gets into their arable land. It is the chiendent of the French, who, I must observe here for the benefit of their husbandry, do not distinguish it sufficiently from our

Rye-grass, which is C. Bauhin's *Gramen loliaceum angustiore folio, et spica*, Darnel-grass, with a narrower leaf and spike; and Linnæus's *Lolium spica mutica*, Darnel with a chaffy spike: for darnel-grass, rye-grass, and ray-grass, are only different names of one and the same plant: though M. Duhamel, misled by the erroneous spelling of some writers, who have called rye-grass, ray-grass, has been mistakenly induced to think, that these are two different plants with us. We distinguish, indeed, two considerably different species of the rye-grass, viz. the foregoing, which, according to Mr. Ray, is the *Lolium rubrum*, or red darnel; and the *Lolium album*, which, according to the same author, is C. Bauhin's *Gramen loliaceum spica longiore*, darnel-grass with a longer spike, and the yvræ of the French, by us commonly called darnel only. But both of them are equally rye-grass. It is the last of these species, viz. the *lolium album*, which is chiefly cultivated in England, especially in strong cold land, upon which it will succeed better than any other species, and is an earlier seed in the spring: but it is very coarse; and unless it be cut quite early for hay, it becomes so hard and wirey in the stalks, that few cattle care to eat it: for this sort of grass has but few leaves, and runs all to stalks. When cattle have been turned in to feed upon it, the remaining stalks or bents, as they are sometimes called, should be mowed off in June; for otherwise they will dry upon the ground, give the pasture the disagreeable appearance of a stubble field during all the latter part of the summer, and be so very troublesome to the cattle which feed on it, by tickling their nostrils, that nothing but the want of better grazing will compel them to eat of the young grass which shoots up between these withered stems; for they will not eat them. Those who think that they do, when straitened for food, are greatly mistaken, according to Mr. Miller, who says, that he has closely attended to this many years, and has always found these bents

remaining, on the ground untouched, till the frosts, rain, and winds, have destroyed them in the winter. Besides this, by permitting them to stand, the after-growth of the grass is greatly retarded, and the beautiful verdure of the fields is lost for three or four months. It therefore is good husbandry to mow them close to the ground, before they become too dry: and if this cutting is then made into hay, it will serve to feed cart-horses in the winter, so as to repay the expence of mowing.

The red darnel is a considerably inferior species of rye-grass; for it has yet narrower leaves, and its stalks grow hard much sooner. It is very common in most pasture grounds, because it flowers early, and its seeds ripen and sow themselves before the hay is cut. They, therefore, who would keep their pastures as clear as possible from this grass, should always mow them before its seeds are ripe.

Rye-grass is usually sown with clover, upon such lands as are designed to be ploughed again in a few years; and a common method is to sow it with spring corn. But Mr. Miller, from many repeated trials, has always found, that when this grass has been sown in August, and a few showers have fallen shortly after, the crop has been by much the best: for then it has often been so high as to afford a good seed the same autumn; and a ton and a half of hay has been mowed early the next spring on each acre of land, though it has been a cold and sour soil. "I am, therefore, says he, convinced of that being the best season for sowing these grasses; though it will be very difficult to persuade these persons to alter their practice, who have been long wedded to old customs. The quantity of seeds which I allow to an acre is about two bushels, and eight pounds of the common clover, which, together, will make as good a covering upon the ground as can be desired. But this is not to be practised upon lands where the beauty of the verdure is principally regarded. It is fittest for those who have only profit in view." However, we must reckon as an abatement in this profit, that, as M. Duhamel rightly observes, the ground that has been under rye-grass, which is not so profitable a crop as either lucerne, saintfoin, or even clover, is not able to bear wheat the next year, as it is after those other plants, or after a crop of roots.

According to Mr. Lisle's information, the farmers in the Isle of Wight prefer rye-grass to hop clover, because, say they, the rye-grass will bear the winter, and keep to a good head, which the clover will not do. One of his tenants there had an acre and a half of rye-grass upon tolerably good ground, which he shut up from Michaelmas till within a month of Candlemas, and from thence to the middle of April it kept fifteen ewes and fifteen lambs.

Rye-grass seldom lasts more than three years, as it is commonly managed: but Mr. Lisle is strongly of opinion, that, considering the nature of its roots, and its manner of propagating itself, by sending forth fibres from its joints, it may be kept alive many years longer, by dunging it, or by refreshing it with soil, when it begins to decay, after the second or third year: besides which, this will make its roots tiller, and mat on the ground, to the utter suppression and destruction of all weeds, not excepting even the couch-grass.

An acquaintance of his near Upcurn, in Dorsetshire, told him, that he had as much rye-grass seed on eighteen acres of land, as was worth twenty pounds; and that, after the seed was threshed out, that hay was better than oat-straw fodder. Mr. Lisle himself saw a rick of this coarse stubbed hay, and a rick of oat-straw, both of which had been laid open to the cattle, in the same place; and they would not touch the straw, but had made such a hole in the rye-grass hay-rick, that it was ready to fall. The same person assured Mr. Lisle, that he found the rye-grass to be excellent food for his cattle, if it was mowed green, and not kept for the lucre of the seed. His usual allowance was three bushels of this seed to an acre of land, and he used to sell it for twenty-two pence, or two shillings a bushel.

Another farmer shewed Mr. Lisle some of his rye-grass, saying, that he looked upon it as his choicest fodder for sheep. He mowed it while in the flower; and Mr. Lisle declared, that he thought it very fine hay. Others again, and those men of experience, have affirmed, that the very stubble of the rye-grass, mowed the same year it was

sowed, is, when ploughed in, as good as dunging, and will pay for the seed.

Mr. Lisle agrees with all other experienced husbandmen, that, though rye-grass will maintain as many cattle on an acre as hop-clover will do; yet it does not, like it, improve the land for a subsequent crop of corn; the reason of which he takes to be, that the roots of the rye-grass, consisting of a multitude of matty fibres, which run on the surface of the ground, gird and hold the earth so strongly together, that they cannot easily be disentangled from it by ploughing.

"If I may judge of this grass, says Mr. Stillingfleet, by the venison I have eaten out of a paddock that was chiefly filled with this species, I would by no means recommend it for parks. I know it will be said, that venison is never good out of paddocks, that the deer must have room to range, trees to browse on, &c. I grant there is some reason for saying this, but I believe in general it is more owing to the want of proper food, viz. good grass, than merely to confinement: for paddocks are generally made out of a rich spot of ground near the house, that has constantly been manured, and of course is full of grass fitter for the dairy or the stable, than for deer; which hardly ever is the case in large parks. No man will, I suppose, pretend to make good pork from a hog fed with grains instead of pease, though he has the liberty of choosing as much ground as he pleases, and where he pleases."

In a subsequent edition of his Observations on Grasses, he adds, "I have since eaten venison out of a large park, where there was much of this grass, and it was no better than that out of the paddock. I should be apt to think from hence, that this grass would not be proper for sheep, as I have always observed that the same kind of ground which yields good venison, yields also good mutton. For what particular uses it is good, wants to be tried; whether for the dairy, for fattening cattle, or for horses. Many are tempted, by the facility of procuring the seed of this grass, to lay down with it grounds near their houses, where they want to have a fine turf: but unless the soil be very rich, a worse grass cannot be chosen for this purpose, as it will certainly die off entirely in a very few years."

The wall-barley, or way-bennet, as some people improperly term it, is evidently from the shape of its ear, and from every other characterising circumstance, a rye-grass, or wild rye, as Mr. Ray observes, though very different from the preceding. It is the *gramen secalinum et secale sylvestre*, called tall meadow rye-grass by Mr. Miller, who reckons it an excellent grass for sowing, because it is very leafy, its stalks do not become stiff and hard like many other species, and its roots are perennial. He seems not to doubt, but that it may be rendered very fine by proper care; and as its roots are perennial, rolling will make them mat so as to form a very close sward. There are three sorts of it, viz. the greater, the lesser, and the marsh rye-grass. Mr. Stillingfleet wishes, that this genus only were to be called rye-grass, and that the old name of darnel were continued to the *gramen loliaceum*, or rye-grass before spoken of.

The two best species of grass for pastures are, in Mr. Miller's opinion, C. Bauhin's *gramen pratense, paniculatum majus, angustiore folio*, meadow-grass, with large panicles, and a narrower leaf, which is the *poa panicula diffusa spiculis, quadrifloribus pubescentibus culmo erecto teretri*, Flor. Succ. 77. Poa with a diffused panicle, the smaller spikes having four hairy flowers, and a taper erect straw; and C. Bauhin's *gramen pratense, paniculatum majus, latiore folio*, meadow-grass, with a larger panicle, and broader leaf which is the *poa panicula diffusa, spiculis trifloribus glabris, culmo erecto teretri*, Flor. Succ. 76. Poa with a diffused panicle, small spikes with three flowers, and an upright straw.

These seem to be the great meadow-grasses Mr. Stillingfleet observes are common in our best meadow grounds. He has also met with them frequently on banks by the road side, and near ditches, even where they were not to be found in the adjoining meadows and pastures. But as he has not favoured us with a botanical description of them, we can only form conjectures.

If the seeds of these two sorts were carefully collected and sown separately, without any mixture of the seed of other grass, they would not only afford a greater quantity of fodder on the same space of land, but the grass would also

also be better, the hay sweeter, and the verdure more lasting, than that of any other species. Mr. Miller recommends this particularly to every gentleman who would improve the verdure near his habitation.

The annual meadow-grass makes the finest of turfs. It grows every where by way sides, and on rich found commons. It is called in some parts the Suffolk grass, as we mentioned before. Mr. Stillingfleet says, he has seen whole fields of it in High Suffolk, without any mixture of other grasses, and as some of the best salt butter we have in London comes from that country, it is most likely to be the best grass for the dairy. See ANNUAL MEADOW GRASS.

As the next best to meadow-grass, Mr. Miller recommends Ray's *gramen avenaceum pratense elatius, panicula flavescens, locustis parvis*, taller meadow oat-grass, with a yellowish panicle and small husks, which is the *avena panicula laxa, calycibus trifloris brevibus, flosculis omnibus aristatis*, Prod. Leyd. 66. Oat-grass with a loose panicle, three flowers in each impalement, which is short, and all the flowers having awns. Mr. Ray likewise recommends the smooth mountain oat-grass, which he calls *gramen avenaceum montanum spica simplici, aristis recurvis*, found by Mr. Dale upon Bartlow hills in Essex, on the edge of Cambridgeshire in the borders of the corn fields between Newmarket and Exning, and on the chalk hills between Northfleet and Gravesend; and the rough or hairy oat-grass, which he distinguishes by the appellation of *gramen avenaceum hirsutum, panicula purpureo argentea splendens*, and which abounds in the pastures about the earl of Cardigan's house at Twickenham, in Middlesex. He also includes under this genus, all the *festuca* kinds, of which Mr. Stillingfleet gives the following account, in his Observation on Grasses, subjoined to his translations of several ingenious tracts, selected from the Transactions of the Academy of Upsal.

Sheep's fescue, which he distinguishes by the name of *festuca ovina*, is the grass most esteemed for the food of sheep in Sweden, where they have not such downs as we have.

Gmelin says, that the Tartars choose to fix, during the summer, in those places where there is the greatest plenty of this grass, because it affords a most wholesome nourishment to all kinds of cattle, but chiefly sheep: and he observes, that the sepulchral monuments of the ancient Tartars are mostly found in places which abound with this grass, which shews, adds he, that it has long been valued among them.

This grass abounds in many parts of England and Wales, and particularly on all the finest sheep pastures in Herefordshire, Oxfordshire, Norfolk, &c. Mr. Stillingfleet observes, that it is a very early grass, and that, contrary to what Linnæus says, either sheep or some other animals do eat the flowering stems of this grass; for, when he searched for it upon Bansted downs, he could see no part of it but the radical leaves, except among bushes near the hedges, where it was guarded from the sheep.

Mr. Stillingfleet says, that he has always seen the purple fescue along with the fine bent and silver hair grass, which will be spoken of hereafter, particularly on Bansted downs, in great plenty, in a place inclosed in order to keep the sheep out. From thence he is inclined to think, that this is the chief grass all over the downs; but as the flowering stems in the other parts were entirely gone at the time of his viewing it, except along the hedges, he could not be certain in this respect.

After candidly declaring his want of knowledge of the qualities of the fescue fescue, which he calls *festuca fluitans*, Mr. Stillingfleet quotes a curious passage in the Transactions of the Academy of Upsal, where the author of a piece entitled *Plantæ Fescentæ* says, that the seeds of this grass are gathered yearly in Poland, and from thence carried into Germany, and sometimes into Sweden, and sold under the name of manna seeds, and that they are there much used at the tables of the great, on account of their nourishing quality and agreeable taste. Mr. Stillingfleet then adds, that one Mr. Dean, a very sensible farmer at Ruseomb, in Berkshire, assured him, "that a field of about four acres, which always lay under water, and was occupied by his father when he was a boy, was covered with a kind of grass that maintained five farm horses in good heart, from April to the end of harvest, without giving them any other kind of food, and that it yielded

more than they could eat." Some of it was carried to Mr. Stillingfleet, who found it to be the fescue fescue, with a mixture of the marsh bent: but whether this last contributes much towards furnishing so good pasture for horses, seems doubtful to him. They both threw out roots at the joints of the stalks, and are therefore likely to grow to a great length.

Linnæus says, that the bran of this grass will cure horses troubled with bots, if they are kept from drinking for some hours.

In the index of dubious plants, at the end of Ray's Synopsis, mention is made of a grass called *gramen caninum supinum longissimum*, longest supine dog's grass, which grows at Maddington in Wiltshire, and in some part of Wales, to the length of twenty-four feet, and is used for the fattening of hogs. Its stalks are of the creeping kind, and touch the ground at several of their knots; for they do not rise much in height. Mr. Stillingfleet thinks it the fescue fescue, and rightly advises farther enquiries concerning it. But he does not seem here to have consulted Mr. Worlidge, who says, speaking of this grass, that it is extraordinarily sweet, but not so easily propagated as hath been imagined, the length thereof being occasioned by the washing of a declining sheep down, from whence hasty rains bring with them much of the fatness of the dung of the sheep, which subsides upon the small meadows where this grass grows: so that in springs not subject to these showers, or on lands not enriched by that fertilising soil brought down to them, this grass does not thrive so well.

The vernal grass, which Mr. Stillingfleet calls *anthoxanthum odoratum*, and which is at least a species of Ray's *gramen vernum spica brevi laxa*, and of C. Bauhin's *gramen vernum pratense spica flavescens*, vernal grass, with a loose yellowish spike, is one of the earliest grasses, and grows very commonly in all our meadows, pastures, and other grounds. It is found in plenty upon those pastures which sheep are fond of, and from whence excellent mutton comes; and therefore it is most likely to be a good grass for sheep pastures. Mr. Stillingfleet says, he has found it on all kinds of grounds, from the most sandy and dry to the most stiff and moist, and even in bogs. It is very plentiful in the best meadows about London, viz. towards Hampstead and Hendon; and its seeds may be gathered very easily, as it sheds them upon the least rubbing. This grass gives a grateful odour to hay.

Mr. Lisle remarks, that the *gramen parvum repens purpurea spica*, small creeping grass, with a purple spike, is no indication of bad ground, though it be a very bad grass. Ray says, that it is very common in pastures. There seems to be a great sweetness in it. The same may be said of the *gramen cristatum*, or smooth crested grass, which also abounds every where in our meadows and pastures.

The meadow fox-tail grass (*gramen alopecuroides*) abounds in our best meadows about London, and makes very good hay; perhaps the best of any that is brought to market here. Mr. Stillingfleet observed in the spring of the year 1762, a meadow near Hampstead which consisted of this grass chiefly, with some of the vernal grass and the corn-broom grass: but it is scarce in many parts of England, particularly in Herefordshire, Berkshire, and Norfolk; though it might be gathered at almost any time of the year, even from hay-ricks, as it does not shed its seeds without rubbing, which is the case of but few grasses.

The water fox-tail (*alopeuroides paludosum*) is also found in such meadows about London as are found and lie under water in the winter. Mr. Stillingfleet thinks it may, perhaps, be a proper grass to sow on such grounds.

Mr. Stillingfleet has always found the fine bent-grass, which he names *agrostis capillaris*, in great plenty on the best sheep pastures, as on Malvern-hills, Bagshot-heath, and all the high grounds in Herefordshire, Berkshire, Oxfordshire, and Norfolk, and other places remarkable for good mutton.

The same may be said of the mountain hair-grass, which he calls *aira flexuosa*; and of the silver hair-grass, which is his *aira caryophylla*.

The quaking-grass, cow-quake, or lady's hair, as it is called in some places, is the *gramen tremulum maximum*, of C. Bauhin, and J. Ray, and the *briza spiculis cordatis, flosculis septendecim*, Hort. Cliff. 23. Briza with heart-shaped

shaped little spikes, and seventeen flowers in each. Though a very poor and slender grass, Mr. Lisle thinks it no indication of poor land where it grows: for, as Mr. Ray observes, it is the most common grass of any in all the pasture grounds throughout England.

Mr. Miller describes it as having an annual root, which sends up many broad hairy leaves, between which arise slender stiff stalks, from a foot to near two feet high, dividing upward into a large loose panicle, garnished with heart-shaped small spikes, each having about seventeen small floscules, or florets; and these, after the flowers are past, are succeeded by a single seed. The heads hang by slender long foot-stalks, which are moved by every wind, so that they generally appear shaking; from whence it had the name of quaking-grass. There is a smaller species of it, which is a native of England; but, I believe, of no greater value than the former. These grasses come to head in May: and this gave rise to the English proverb, May, come she early come she late, makes the cow quake.

Matweed (*gramen spartcum*) is of the broom kind, and delights in sandy places near the sea. Even clouds of sand blown over it do no hurt, but on the contrary promote its growth. It has been of excellent service in fixing loose sands, as, if I have been rightly informed, it once did very remarkably in Norfolk. Of ten species of this plant, which Mr. Ray distinguishes, the following are the chief. 1. *Spartium Plinii*, five *juncus Hispanicus*, the true matweed of Pliny, or Spanish broom; 2. *Gramen spartcum paniculâ brevi folliculo inclusâ*, hooded matweed; 3. *Gramen spartcum maritimum Anglicanum*, English sea matweed, or marram; 4. *Spartum maximum maritimum Hollandicum*, spica *secalinâ*, the greatest Holland matweed; with a rye spike; 5. *Gramen spartcum pennatum*, Feather-grass; and 6. the *Gramen spartcum juncifolium*, or *spartum parvum*, small matweed.

Mr. Stillingfleet says, that the best mutton he ever tasted, next to that which comes from hills, where the purple and sheep's fescue, the fine bent, and the silver hair grasses abound, was fed upon the crested dog-tail grass, which he and Mr. Hudson call *cynofurus crystallus*. He therefore rightly judges it proper for parks; and confirms this opinion, by adding, that he knows a park where this grass abounds, which is famous for excellent venison. It makes a very fine turf upon dry, sandy, or chalky soils: but unless it be swept over with the scythe, its flowering stems will look brown; as is the case of all grasses which are not fed by a variety of animals: for that some animals will eat the flowering stems, is evident from commons, where one scarcely sees any part of the grasses, except the radical leaves.

Mr. Miller thinks the cock's foot grass (Ray's *Gramen dactylon*, Hist. p. 1271) the capon's-tail grass (Ray's *Gramen murorum spicâ longissimâ*, Hist. p. 1286) and the millet grasses (*Gramina maliacea*) too coarse to deserve attention in England; though some of their species are very useful in the warm parts of America, where there is a great scarcity of finer grass, and even much better adapted for such climates, than any of our European grasses; because many of them lie flat on the ground, and emit roots from their joints, by which means they are well prepared for heat; of which their large and juicy stalks likewise enable them to bear an extraordinary degree.

The purple, or, as it is commonly called, red meadow trefoil, which is C. Bauhin's *Trifolium pratense purpureum*, has already been sufficiently distinguished from the common red clover, or red honey-suckle (Ray's *Trifolium purpureum majus*, *pratense simile*, Sym. 328) which, though Mr. Lisle thinks otherwise, is undoubtedly a native of England, as is manifest from its spontaneous and flourishing growth on the top of many mountains, particularly in even the most northern parts of Scotland, where no mortal surely ever dreamt of cultivating it. The species called yellow meadow trefoil, or hop-clover, is C. Bauhin's *Trifolium pratense luteum, capitulo lupuli, vel agrarium*; and the smaller kind of this, commonly called nonesuch, or black seed, is the *Trifolium luteum, lupulinum minimum*. M. Duhamel rightly prefers the first of these sorts for artificial pastures, and observes, that it is the only species now cultivated in France for that purpose.

Our meadows afford us the white meadow-trefoil, honeysuckle-grass, or white Dutch clover, which is the *tri-*

folium pratense album of C. Bauhin, and by far the best sort of clover for lasting pastures, because it is the sweetest and most abiding of all plants of this kind. See CLOVER.

I do not know that the narrow-leaved plantain, or ribwort (*Plantago angustifolia*) hath ever been cultivated purposely for the food of cattle. It grows, indeed, in almost all pastures: but, as it will thrive upon very dry spots, because it strikes a deep root, it may probably deserve farther trial.

The late Dr. Eliot recommends two sorts of grasses, natives of North America, of which he lately sent over a parcel of the seeds to the London Society for the Encouragement of Arts, &c. by whom they have been distributed here, so that we may hope soon to know their success in this country, and of which he has given an account in his Essays upon Field Husbandry in New England. See the articles BIRD-GRASS, and TIMOTHY-GRASS.

GRASS-*Lease*, grass-lands, or lands appropriated to grass for feeding of cattle.

GRATTEN, a term used in Cornwall, to imply the mowing of grass, the first year after the land has been manured with sea-sand; and this operation they call mowing in gratten.

GRAVELLING. A misfortune that happens to a horse by travelling, by little gravel stones getting between the hoof and the shoe, which settles at the quick, and there festers and frets.

The way to cure it, is to take off the shoe, and then to draw the place with a drawing iron till you come to the quick; pick out all the gravel, and squeeze out the matter and blood found therein, and afterwards wash it clean with copperas water, then pour upon it sheeps tallow and bay salt melted together, scalding hot, stop up the hole with hards, and set the shoe on again, and at two or three times dressing it will be whole; but do not travel or work him before he is quite well, or let his foot come to any wet.

GRAVELLY-Land, that which abounds with gravel and sand. See the article SANDY-LAND.

The best manure for this sort of land is marl, or any stiff clay that will dissolve with the frost, cow-dung, chalk, mud, and half rotten straw from the dunghill.

GRAZING. Mr. Marshall, in his Rural Economy of the Midland Counties, says that "the midland district viewed collectively, is a grazing country. South and East Leicestershire, and much of Northamptonshire fall entirely under this description. Warwickshire, inclines more to the dairy.

The species of grazing, which is here practised, is, in a manner solely, summer fattening on grass. Some may, every year, be finished with hay and kept pasture: and a few individuals practise stall-fattening, on hay and what is called "cutmeat;" namely, oats in straw, cut in a chaff machine; and some, but very few, on oilcake.

GRAZING in a wet season. I cannot with propriety omit mentioning, in this place, an incident of practice which has occurred to me, this autumn, 1789, a very wet year.

The general complaint is, that grazing stock, though they have this year rolled in grass, have not done well; Mr. Henton, of Hoby (in Leicestershire) being singular in saying, that his feeders have done tolerably. Indeed, his stock corroborate his assertion. He had a lot of cows at Loughborough, the 12th of August, the fattest in the show.

But his management is more remarkable than his success. He "foddered them with hay all the wet weather;" that is, he mowed the broken grass for them, beginning under the hedges, and continuing to mow the coarsest patches, throughout the piece.

The first day (the day it was mown) the cattle seldom touched it; but the second or third day, they fell to it freely; eating it "between whites," in preference to grass. "In the morning it was always the first thing they filled their bellies with."

The cattle having eaten up the more palatable parts of the herbage, the thistles and other offal were raked up, and carried off the ground: most excellent management!

His stock consisted of about sixty head. At first, one man, only, was employed in mowing, &c. But, before the rainy weather ceased, he set on another man.

What an admirable thought! that which other men suffered to stand waste in itself, an encumbrance to the ground

ground, and a nursery of weeds, was converted to a food, more nutritious, in a wet season, than the best of the standing herbage.

The fairs at Birmingham are among the worst in the country, for fat stock! the butchers giving the graziers no encouragement to drive their stock to them: preferring the toil of riding twenty, thirty, or perhaps forty miles from home, to pick up their "fat!" spending a principal part of their time, and their profits, in an employment, truly ridiculous.

How convenient it would be to the grazier, as well as to the butcher, to have a weekly market—a Smithfield, at or near Birmingham! to the grazier, in thereby having a constant and certain market, whenever he wanted either keep or money; and to the butcher, in saving time and travelling expences. Yet the few which are taken there, at present, are frequently drove out unfold!

But, at present, the day, Thursday, the ordinary market day, is improper: Monday or Tuesday would be a more suitable day: and Sutton, perhaps the most suitable place.

For further particulars, see the articles FATTENING CATTLE, FLAX-SEED, &c.

GREASE, a disease incident to horses and other cattle, consisting of swellings and gourdinens of the legs.

In order to treat this disorder with some propriety, without having recourse to the falling down of humours for its explanation, we shall consider it as arising from two different causes; a fault or relaxation in the vessels, or a bad disposition of the blood and juices. In order to this, it will be necessary to observe, that the blood and juices are carried to the extreme parts by the arteries, and returned by the veins; consequently the blood must rise perpendicularly in the latter, in order to return from the extremities to the heart. And hence swellings in the legs of horses may be easily accounted for, as a partial stagnation of the blood and juices may be naturally expected where the circulation is languid, especially when there is a want of due exercise, and a proper muscular compression on the vessels to push forward the returning blood, and propel the inert, and half-stagnating fluids through their vessels. In short, the blood, in such cases, cannot so easily ascend as descend, or a greater quantity will be brought by the arteries than can be returned by the veins.

The grease then, considered in this light, must be treated as a local complaint, where the parts affected are alone concerned, the blood and juices being yet untainted; and in good condition; or as a disorder where they are both complicated: but when it is an attendant on some other distemper, as the farcy, yellow dropsy, &c. such diseases must first be cured before the grease can be removed. In the former case, moderate exercise, proper dressing, cleanliness, and external applications, will answer the purpose; in the latter, internals must be called into our assistance, with proper evacuations.

When a horse's heels are first observed to swell in the stable, and subside, or go down, on exercise, let care be taken to wash them very clean every time he comes in, with soap-suds, chamberlye, or vinegar and water, which, with proper rubbing, will frequently prevent or remove this complaint: or let them be well bathed twice a day with old verjuice, or the following mixture, which will brace up the relaxed vessels; and if rags dipped in the same are rolled on, with a proper bandage, for a few days, it is most likely the swellings will soon be removed by this method only, as the bandage will support the vessels till they have recovered their tone. To answer this end also, a laced stocking, made of strong canvas, or coarse cloth, neatly fitted to the part, would be found extremely serviceable, and might easily be contrived by an ingenious mechanic.

Take rectified spirit of wine four ounces, dissolve in it half an ounce of camphor, to which add wine-vinegar, or old verjuice, six ounces; white vitriol, dissolved in a gill of water, one ounce; mix together, and shake the phial when used.

But if cracks or scratches are observed, which ooze and run, let the hair be clipped away, as well to prevent a lodgment (which becomes stinking and offensive by its stay) as to give room for washing out dirt or gravel, which, if suffered to remain there, would greatly aggravate the disorder.

When this is the case, or the heels are full of hard scabs it is necessary to begin the cure with poultices, made either of boiled turnips and lard, with a handful of linseed powdered, or oat-meal and rye-flour, with a little common turpentine, and hog's lard, boiled up with strong beer grounds, or red wine lees. The digestive ointment being applied to the sores for two or three days, with either of these poultices over it, will, by softening them, promote a discharge, unload the vessels, and take down the swelling, when they may be dried up with the following:

Take white vitriol and burnt alum, of each two ounces; Ægyptiacum one ounce; lime water a quart, or three pints: wash the sores with a sponge dipped in this, three times a day, and apply the common white ointment, spread on tow; to an ounce of which may be added two drams of sugar of lead.

Or the following wash and ointment may be used for that purpose:

Take half an ounce of Roman vitriol, dissolved in a pint of water; then decant off the clear into a quart bottle, add half a pint of camphorated spirits of wine, the same quantity of vinegar, and two ounces of Ægyptiacum.

Take honey four ounces, white or red lead, powdered, two ounces; verdigrise, in fine powder, one ounce: mix together.

Some, for this purpose, apply alum-curd; others a strong solution of alum in verjuice, with honey; and many of these forms may be easily contrived. But let it be remembered, that as soon as the swelling is abated, and the moisture lessened, it would be very proper to keep the legs and patterns rolled up with a firm bandage, or linen roller, two or three fingers wide, in order to brace up the relaxed vessels, till they have recovered their natural tone.

This method is generally very successful when the distemper is only local, and requires no internal medicines: but if the horse be full and gross, his legs greatly gorged, so that the hair stands up, and is what some term pen-feathered, and has a large stinking discharge from deep foul sores, you may expect to meet with great trouble, as these disorders are very obstinate to remove, being often occasioned by a poor dropical state of the blood, or a general bad disposition in the blood and juices.

The cure in this case, if the horse is full and fleshy, must be begun by bleeding, rowels, and repeated purging; after which, diuretic medicines are frequently given with success. Thus,

Take four ounces of yellow rosin, one of sal prunella; grind them together with an oiled pestle; add a dram of oil of amber, and give a quart of forge-water every morning, fasting two hours before and after taking, and ride moderately.

As this drink is found very disagreeable to some horses, I would recommend the nitre balls in its stead, giving to the quantity of two ounces a day, for a month or six weeks, mixed up with honey, or in his feeds: take the following also for that purpose.

Yellow rosin four ounces, salt of tartar, and sal prunella, of each two ounces Venice soap half a pound; oil of juniper half an ounce; make them into balls of two ounce weight, and give one every morning.

Or,

Take nitre two ounces; camphor one drachm; honey enough to make into a ball: give as the former.

The legs in this case should be bathed or fomented, in order to breathe out the stagnant juices, or to thin them, so that they may be able to circulate freely in the common current. For this purpose foment twice a day with a discutient fomentation, in which a handful or two of wood-ashes has been boiled; apply then the above poultice, or the following, till the swelling has subsided, when the sores may be dressed with the green ointment till they are properly digested, and

then dried up with the water and ointment above recommended.

Take honey one pound, turpentine six ounces, incorporate with a spoon; and add of the meal of fenu-greek and linseed, each four ounces; boil in three quarts of red wine lees, to the consistence a poultice; to which add, when taken from the fire, two ounces of camphor in powder; spread it on thick cloths, and apply warm to the legs, securing it on with a strong roller.

If the sores are very foul, dress them with two parts of the wound ointment, and one of *Ægyptiacum*; and apply the following, spread on thick cloths, and rolled on.

Take of black soap, one pound; honey, half a pound; burnt alum four ounces; verdigrise powdered, two ounces; wheat flour, a sufficient quantity.

If the diuretic balls should not succeed they must be changed for the antimonial and mercurial alteratives already mentioned; but turning a horse out in a field, where he has a hovel or shed to run to at pleasure, would greatly contribute to quicken the cure; and, indeed, would in general effect it alone: but if this cannot be complied with, let him be turned out in the day time.

If the horse is not turned out, a large and convenient stall is absolutely necessary, with good dressing, and care: this stall should be six feet wide, that a tall horse may shoot out his legs at length, so that the blood may circulate freely, without meeting with resistance, which it naturally must, when a horse lies all on a heap, or with his hind legs under him: nor should the stable be paved with too great a declivity, for if the horse stands too low with his hind legs, most of his weight will rest upon them; and give him the grease, especially if he be at all inclined to be gourd.

The last thing we shall recommend, is to make him lie down in the stable as often as possible. This is undoubtedly of the utmost consequence, as it will not a little contribute to the removal and cure of this disorder: for by only changing the position of his legs, a free circulation would be obtained, and the swelling taken down; whereas it is in general greatly aggravated by the obstinacy of the horse, which refuses to lie down at all, probably from the pain it gives him in bending his legs necessary for that purpose; by which means the stiffness and swelling increases, till the over-gorged and distended vessels are obliged to give way, and, by bursting, discharge the fluids that should circulate through them. *Barlet's Farriery*, p. 284.

GREASE melted. See the article *MOLTEN GREASE*.

GREEN-SCOURING, a disease to which sheep and bullocks are often subject.

The best remedy for this disease is verjuice; a wine-glass full is enough for a sheep, and a pint for a bullock. *Lisle's Husbandry*, vol. II. p. 211.

GREEN-BUGS, which destroy plants in gardens, may be destroyed by sprinkling the places where they lodge with the juice of henbane infused in vinegar. Or the plants on which they settle may be watered with the cold decoction of mustard and laurel-seed, mixed with water.

GRIP, or *Gripe*, a small ditch cut across a meadow or ploughed-field, in order to drain it. It is otherwise called a water-furrow.

GRIPES, a very acute disease to which horses are very often subject.

There seems to be no distemper so little understood by the common farrier, as the gripes or cholic in horses; one general remedy, or method, serving them in all cases; but as this disorder may be produced by very different causes, the cure must also vary, otherwise the intended remedy, injudiciously applied, will not only aggravate the complaint, but make it fatal. We shall divide this disorder into three different species: the flatulent or windy, the bilious or inflammatory; and the dry gripes; each of which we shall distinguish by their different symptoms, and then point out the proper remedies.

The flatulent, or windy cholic is thus known. The horse is often lying down, and as suddenly rising again with a spring; he strikes his belly with his hinder-feet, stamps with his fore-feet, and refuses his meat; when the gripes are violent, he will have convulsive twitches, his eyes be turned up, and his limbs stretched out as if dying, his ears and feet being alternately very hot and cold; he falls into pro-

fuse sweats, and then into cold damps; strives often to stale, and turns his head frequently to his flanks; he then falls down, rolls about, and often turns on his back; this last symptom proceeds from a stoppage of urine, that almost always attends this sort of cholic, which may be increased by a load of dung pressing on the neck of the bladder.

These are the general symptoms of cholic and gripes from wind, drinking cold water when hot, and when the perspirable matter is retained, or thrown on the bowels by catching cold; in all which cases they are violently distended. Cribbing horses are more particularly subject to this complaint, by reason they are constantly sucking in great quantities of air.

The first intention is to empty the strait gut with a small hand dipt in oil, which frequently makes way for the confined wind to discharge itself; and by easing the neck of the bladder, the suppression of urine is taken off, and the horse stales and gets ease.

Farriers generally strike a steam in the bars of a horse's mouth, which seems to be of little or no use; for where a quantity of blood is intended to be taken away, the vessels of this part are neither large or numerous enough to furnish it; so that it is more eligible to take it from the neck-vein, and is always proper in full, sanguine, plethoric, young horses.

The following ball and clyster seldom fail of giving relief in these cases:

Take Strasburgh or Venice turpentine, and juniper berries pounded, of each half an ounce; sal-prunella, or salt-petre, an ounce; oil of juniper, one dram; salt of tartar, two drams; make into a ball, with any syrup: it may be given whole, and washed down with a decoction of juniper-berries, or a horn or two of ale.

If the horse does not break wind, or stale plentifully, he will find no relief; therefore in an hour or two give him another ball, and add to it a dram of salt of amber; which may be repeated a third time, if found necessary. During the fit the horse may be walked and trotted gently, but should by no means be harrassed beyond his ability, or dragged about till he is jaded.

The following clyster may be given, between the balls, or alone, and repeated occasionally:

Take camomile flowers, two handfuls; anise, coriander, and fennel seeds, of each an ounce; long pepper, half an ounce: boil in three quarts of water to two; and add Daffy's elixir, or gin, half a pint; oil of amber, half an ounce; and oil of camomile, eight ounces.

The subsequent balls and drink are also very proper for this purpose, and to remove gripes occasioned by drinking cold water when hot, or catching cold after violent exercise:

Take powder of anise, cummin, and fennel-seeds, of each half an ounce; camphor, two drams; pellitory of Sapin, one dram; oil of juniper, fifty drops: make into a ball with any syrup, and wash it down with a horn or two of ale.

Or,

Take mithridate, or Venice treacle, two ounces; Matthew's pill, two drams; camphor, one dram, dissolved in a little spirit of wine; powder of fresh aniseed one ounce; or the same quantity of the cordial-ball; dissolve in a pint and half of ale.

Or,

Take philonium, one ounce, or an ounce and an half; tincture of senna, or Daffy's elixir, and sallad-oil, of each half a pint: give warm for a drink, and repeat it if necessary.

Either of these medicines are well calculated for this purpose; but as the ingredients may not always be ready at hand, or procurable, we shall put down a couple of drinks that have frequently, on trial, been found successful, and are easily prepared. It is to be observed, that the horse should be well rubbed, clothed, and littered with clean straw up to his belly.

Take

Take of Castile-soap or hard-soap, nitre or salt-petre, of each one ounce ; juniper-berries and ginger, each half an ounce ; Venice turpentine, or rosin, dissolved with the yolk of an egg, six drams : mix with a pint and a half of warm ale, or a decoction of juniper-berries, with a large onion boiled with them. This may be repeated twice or thrice.

Or,

Take a pint of brandy, rum, or Geneva, with as much sweet oil, and give for a drink. Should this not succeed, boil an ounce of pepper or ginger, in a quart of milk ; and add to it a handful of salt, and half a pint of oil : this given warm, will (according to Burdon) purge in two or three hours.

The signs of a horse's recovery, are his lying quiet, without starting, or tumbling, and his gathering up his legs, and ceasing to lash out ; and if he continues an hour in this quiet posture, you may conclude all danger over.

The next species of cholic we shall describe is the bilious or inflammatory, which, besides most of the preceding symptoms, is attended with a fever, great heat, panting, and dryness of the mouth ; the horse also generally throws out a little loose dung, with a hot scalding water, which when it appears blackish, or of a reddish colour, and fetid smell, denotes an approaching mortification.

In this case the horse should immediately be bled to the quantity of three quarts ; and it should be repeated if the symptoms do not abate in a few hours. The emollient clyster, with two ounces of nitre dissolved in it, should be thrown up twice a day, to cool the inflamed bowels ; plenty of gum arabic-water should be taken ; and a pint of the following drink given every two or three hours, till several loose stools are procured ; and then it should be given only night and morning, till the disorder is removed.

Take fenna, three ounces ; salt of tartar, half an ounce ; infuse in a quart of boiling water an hour or two ; then strain off, and add two ounces of lenitive electary, and four of Glauber salts.

If this disorder is not removed by these means, but the inflammation and fever increase, attended with a discharge of the flesh-coloured water above described, the event will most probably be fatal ; and the chief thing to be depended on now, must be a strong decoction of Jesuit's bark, given to the quantity of a pint every three hours, with a gill of red port-wine.

A quart of the same may be used for a clyster, with two ounces of Venice turpentine, dissolved with the yolks of two eggs, an ounce of diascordium, and a pint of red wine, and given twice a day : if the horse recovers, give two or three mild rhubarb purges.

To a horse of little value, give the following, which in these cases has been found successful.

Take diapente, one ounce ; diascordium, half an ounce ; myrrh, in powder, two drams : make it into a ball with two drams of oil of amber, to be given twice or thrice a day.

The last we shall describe is the dry gripes, or the cholic, which arises often from costiveness ; it is discovered by the horse's frequent and fruitless motion to dung, the blackness and hardness of the dung, the frequent and quick motion of his tail, the high colour of his urine, and his great restlessness and uneasiness.

In this case the strait gut should be examined and emptied, with a small hand, oiled properly for that purpose ; the emollient oily clyster, given under the article CLYSTER, should be thrown up twice a day ; and the above purging drink given, till the bowels are unloaded, and the symptoms removed.

The diet for a horse in the gripes should be scalded bran, warm water-gruel, or white water, made by dissolving four ounces of gum arabic in a quart of water, and mixing it with other water.

From this history and division of gripes and cholics, with their different treatment, it appears how absolutely necessary it is they should be well understood, in order to be managed skilfully : it is plain, too, that violent hot medicines should, in every species of this disorder, be guarded against, and given with great caution and discretion, even in the first kind of stultent cholic, where indeed they can only be wanted ; yet two often, when prepared by the farriers, with

oil of turpentine, Geneva, pepper, and brine, &c. they even increase that disorder, by stimulating the neck of the bladder too forcibly heating the blood, and inflaming the bowels, till a mortification is brought on them. These are in general the constant appearance of horses that die of this disorder, whose bowels, being examined for that purpose, have been found inflamed, full of red and livid spots, sometimes quite black, crisped with extreme heat and rotten.

GRIPS, the swaths, or small heaps of corn, lying in the field, as it is cut down with the scythe or sickle.

GROATS, oats, after the shells are taken off.

GROOM, a man who looks after horses, and should demean himself after so gentle and so kind a manner towards horses, as to engage them to love him ; for a horse is reckoned one of the most loving creatures to man of all other brutes, and in every respect the most obedient.

Therefore if he be dealt with mildly and gently his kindness will be reciprocal ; but if the groom or keeper be harsh and cholerick, he will put the horse out of patience, and make him become rebellious, and occasion his biting and striking.

Therefore the groom should frequently dally, toy, and play with the horses under his care, talking to them, and giving them good words, leading them out into the sunshine, there run and shew them all the diversions he can.

He must also duly curry-comb and dress him, wipe away the dust, pick and clean him, feed, pamper, and cherish him ; and constantly employ himself in doing something about him, as looking to his heels, taking up his feet, rubbing upon the soles, &c.

Nay, he ought to keep him so well dressed, that he may almost see his own face upon his coat ; he must likewise keep his feet stopped and anointed daily, his heels free from scratches, and other sores, ever having a watchful eye over him ; and overlooking all his actions, as well feeding as drinking ; that so no inward infirmity may seize upon him ; but that he may be able to discover it, and endeavour to cure. The qualifications necessary in a groom, are obedience, fidelity, patience, diligence, &c.

First, he ought to love his horse in the next degree to his master, and endeavour by fair usage to gain a reciprocal love from him, and an exact obedience ; which if he knows how to pay his master, he will the better be able to teach it his horse ; and both the one and the other are to be obtained by fair means, rather than by passion and outrage. For those who are so irrational themselves, as not to be able to command their own passions, are not fit to undertake the reclaiming of an horse, who is by nature an irrational creature.

He must then put in practice the patience, which he ought at all times to be master of, and by that, and fair means, he may attain his end : for no creature is more tractable than a horse, if he be used with kindness to win him.

The next thing requisite to a groom is neatness, as to keeping his stable clean swept, and in order ; saddles, housings-cloths, stirrups, leathers and girths clean, and above all his horse clean dressed and rubbed.

Lastly, diligence is requisite in a daily discharge of his duty, and observing any the smallest operation, whether casual or accidental, either in his countenance, as symptoms of sickness ; or in his limbs and gait, as lameness ; or in his appetite, as forsaking his meat ; and immediately upon any such discovery to seek out a remedy.

This is the substance of the duty of a groom in general.

We will suppose *Bartholemew-tide* to be now come, and the pride and strength of the grass to be now nipped by the severe frosts and cold dews which usually accompany this season, so that the nourishment thereof turns into raw crudities, and the coldness of the night (which is injurious to horses) abates as much flesh and lust as he getteth in the day, whereof he is now to be taken up from grass, whilst his coat lies smooth and sleek.

The horse designed for hunting, &c. being brought home, the groom must set him up for that night in some secure and spacious place where he may evacuate his body, and so be brought to warmer keeping by degrees ; and the next day set him up in the stable.

It is indeed held a general rule amongst grooms, not to clothe or dress their horses till two or three days after their stabling ; but there seems no other reason but custom for this practice.

Some also give the horse wheat-straw to take up his belly at his first housing ; but others utterly disapprove of it.

For

For the nature of a horse being hot and dry, if he feeds on straw which is so likewise, it would straiten his guts, and cause an inflammation in his liver, and by that means distemper his blood; and besides it would make his body so costive, that it would cause a retention of nature, and cause him to dung with great pain and difficulty, whereas full feeding would expel the excrements according to the true intention and inclination of nature. Therefore let moderate airing, warm clothing, good old hay, and corn, supply the place of wheat-straw.

The first business of a groom after he hath brought his horse into the stable, is, in the morning, to water him, and to rub his body over with a warm whisp, a little moistened, and afterwards with a woollen cloth; also to clean his sheath with his wet hand from all the dust it had contracted during his running, and to wash his yard either with white-wine or water.

He must then trim him after the manner that other horses are trimmed, except the inside of his ears, which ought not to be meddled with for fear of making him catch cold.

In the next place he must take him to the farrier's, and there get him shod with a set of shoes, answerable to the shape of his feet, and not to pare his feet to make them fit his shoes.

Let his feet be well opened between the quarters and the frush, to prevent his being hoof-bound, and let them be opened straight, not sideways; for by that means, in two or three shoeing, his heels (which are the strength of his feet) will be cut quite away. Pare his foot as hollow as you can, and then the shoe will not press upon it.

The shoe ought to come near the heel, but not to be set so close as to bruise it, nor yet so open as to catch in his shoes, if he happens to over reach at any time, and so hazard the pulling them off, the breaking of the hoof, or bruising of his heel.

The webs of his shoes ought to be neither too broad nor too narrow, but of a middling size, about the breadth of an inch, with stopped spunges, and even with his foot; for though it would be for the advantage of a travelling horse's heel, to have a shoe set a little wider than the hoof on both sides, that the shoe may bear his weight, and not his foot touch the ground, yet the hunter being often forced to gallop on rotten spongy earth; if he have them larger it would hazard his laming, and pulling off his shoes, as has been before observed.

There is an old proverb, *before behind and behind before*; that is, in the fore feet the veins lie behind, and in the hinder feet they lie before; therefore the farrier ought to take care that he does not prick him, but leave a space at the heel of the fore feet, and a space between the nails at the toe.

Having got his shoes set on as above directed, a great deal of his hoof will be left to be cut off at his toe.

That being cut off, and his feet smoothed with a file, he will stand so firm, and his feet will be so strong, that he will tread as boldly on stones as on carpet ground.

The horse being shod, and it being time to water him, let him stand in the water, which will (in the opinions of some) close up the holes, which the driving of the nails has made.

Afterwards have him gently home, tie him up to the rack, rub him all over, body and legs, with dry straw, then stop up his feet with cow-dung, give him a quartern of clean sifted old oats, and a quantity of hay, sufficient to serve him all night, and leave him till the next morning.

GROUND, a general name for land, be the soil what it will.

The Romans were very attentive to examine the nature of the ground before they broke it up, and distinguished it into three situations, champaign, hilly, and mountainous. They rightly approved most of a champaign country, declining gradually from the foot of a hill toward the south, or south-east; if a hill rising gently; and if a mountain neither lofty, nor rugged, but covered with plenty of wood and grass. Either of these situations is eligible, according to the purpose for which the ground is intended; some plants affecting hotter, others colder exposures; some delighting to dwell on hills, others in vallies; and some again being indifferent to either: but generally speaking, most vegetables choose the warm and kindly soil of low grounds, fertilised by what the rains bring down to them from the hills and more elevated parts.

The spontaneous produce of the earth is an infallible indication of the nature and quality of the ground. Wild thyme shews it to be good for feeding cattle; betony and

straw-berries direct to wood; camomile points out a mel-low soil fit for wheat; burnet indicates land fit for pasture; and mallows denote it proper for the uses of the kitchen-garden, as has been observed by lord Bacon, Mr. Evelyn, and others.

On the contrary, says the last mentioned of these writers, some ground is so cold, as naturally to bring forth nothing but gorse, broom, holly, yew, juniper, ivy, box, &c. which may perhaps direct us to the planting pines, firs, and other perennial verdures in such places.

Moss, rushes, wild tanfy, sedge, flags, fern, yarrow, and withered, blasted, shrubby, and curled plants, are natural indications of a very bad soil.

The nature of the ground may also be pretty well guessed at, by the quality of the water which runs, or is strained through it.

By the smells, which, upon the falling of the first rains after a long drought, is very pleasing, and even fragrant, from good and natural mould; but disagreeable and noxious, if the ground contains any mineral, or other ill quality, as is remarkable in marshes and fenny places.

By the taste, all earths, as well as plants, abounding more or less in their peculiar salts; some sweet and grateful; others bitter, hot, or astringent; and others flat and insipid; easily discovered by the method which Columella directs, of digging up some of the under mould, out of that part of the land which is deemed the worst, and mixing it thoroughly in an earthen vessel, with sweet water, which, when poured off after the grosser parts have subsided, will retain the taste of the earth soaked in it.

The touch will immediately shew whether it be soft, pliant, fat, and slippery; whether it sticks to the fingers, or melts and dissolves on the tongue; in which case the soil may be deemed rich. If it be gritty, light, and porous, it is bad.

Mould fit for the production of plants is of an uniform substance, unmixed with the contrarieties of soft and hard, churlish and mild, moist and dry: neither is it too unctuous or too lean; but light, and crumbles easily; yet is consistent enough to be wrought and kneaded. It is of such due tenacity as to retain a just degree of moisture, and neither soils the fingers, nor cleaves much to the spade, which easily enters it. Of this kind is the soil usually found under the turf of pasture-grounds, upon which cattle have been long fed and foddered. In short, that is the best mould which is blackest, cuts like butter, sticks not obstinately, breaks into small bits, smells sweet, is tempered without crusting or chopping in dry weather, or becoming poachy in wet, which shines after the plough, where flocks of crows follow the ploughman, and, as Pliny expresses it, peck at his very heels.

As to colour, next to the blackish, the pre-eminence is generally given to the darker grey, and after that to the russet: the clear tawny is reputed worse: the light and darsh ash-colour (light of weight and resembling ashes) good for very little: and the yellowish red, the worst of all.

The common opinion, that all grounds are red or brown; cold and dry, blackish; cold and moist, whitish; hot and moist, ruddy; is, notwithstanding the specious arguments alledged in favour of it, from the exhalation of minerals, the heat of the sun, and other accidents, exploded by Columella, who proposes, as a much surer way to judge of the goodness of land, digging a trench, and afterwards throwing back the same earth that was dug out, treading it down well when it is returned. If, says he, through a kind of ferment as it were, there be more than enough to fill the trench, it is a certain sign that the soil is fat: if there be not enough, we may be sure that it is poor and lean; and if the quantity be just sufficient to fill the whole from whence it was taken, it is of a middling quality.

Mr. Evelyn, after examining the component parts of several sorts of soils, concludes, that the very finest earths and best moulds, however to appearance mixed with divers imperfect bodies, may, for aught we know, consist more of sandy particles than of any other whatever. Hence he infers, that earth, stript of all heterogeneous particles, retains only weight, and an insipid siccity; and doubts whether it affords any thing more than embracement to the first rudiment of plants, protection to the roots, and stability to the stem; being "unprolific till married to something of a more masculine virtue, which irradiates her womb: but otherwise, nourishing only from what is added, with-

without any action or material contribution : for, says he, what gives the divers tempers to moulds, seems rather to be caused by the perpetual and successive rotting of vegetable and animal substances, than by any peculiar and separate principle ; the clamminess of the earth seeming rather something extrinsecal and accidental to it, than natural and originally constitutive. We know indeed, that the earth is, without any artificial auxiliaries, indued with a wonderful prolific virtue : but as this is liable to be lost, or to decay, and never can be expected from some grounds, without helps, it may be worth our while to consider by what expedients the desired effects of perpetuating its vigour may best be accomplished.

The means of giving and perpetuating this vigour now becomes properly the subject of our farther enquiry, consistent with what was observed before, that in order to the earth's having this vigour, it should be constantly kept in an alkaline or calcareous state. Mr. Evelyn is clearly of this opinion, when he says, " I firmly believe that were salt-petre to be obtained in plenty, we should need but little other compost to meliorate our ground." In other words, could the earth be always kept in a state fit for collecting nitre, it would consequently be always in a state fit for the production of plants. They who are acquainted with chemical researches, know, that nitre is obtained from substances of a mixed nature. Its basis is a calcareous earth, to which must be added putrid or alkaline substances, especially of the vegetable kind.

Mr. Evelyn and some later writers have spoken so much of the effects of nitre, and nitrous earths, in vegetation, that many have imagined nitre to be essentially necessary in the growth of plants : though Dr. Woodward assures us, that, by all the trials he has been able to make, the very contrary seems to be the case ; for that nitre, when contiguous to a plant, rather destroys than nourishes it. When, therefore, they mention nitre, and nitrous earths, it is more than probable that they mean earth in a state fit for collecting nitre : but when the alkaline substances are once saturated by the acid in the air, or when the alkali is brought to a neutral salt, as nitre is, its fertile state then ceases, and it becomes a hard compact body, much more impervious to the roots of plants than it was before.

The nature of calcareous substances, and that of the two kinds of alkali, viz. the fixed alkaline salt of plants, and the volatile alkali arising from animal and putrid vegetable substances, has already been explained.

Farmers commonly say, that lime (to which might be added all other calcareous substances) does not fatten, but only mellows the earth ; meaning, according to Dr. Woodward, that it does not contain in itself any thing of the same nature with the vegetable mould, or, in other words, afford any matter fit for the formation of plants ; but that it only softens and relaxes the earth ; by that means rendering it more capable of entering into, and of nourishing the seeds and vegetables set in it, than would otherwise be. It is well known how apt lime is to be put into a ferment and commotion by water. Now this commotion can never happen when the lime is mixed with earth (and it retains its qualities of lime) however hard and clodded the ground may be, without opening and loosening it. What Dr. Woodward says of salt in general, may more properly be applied to the fixed alkaline salt of plants. Every one, says he, must have observed, how apt all sorts of salts are to be wrought upon by moisture, and how easily they melt and run with it. When this happens to those that are in the earth, the clods which they are mixed with, moulder and fall asunder. The same gentleman farther observes, that if we would render the earth truly fruitful, it must be by the addition of such substances as former crops have robbed it of, or such as contains in itself vegetable matter.

The several manures which are found best to promote this end, are chiefly, either parts of vegetables, or of animals ; of animals, says the doctor, which either derive their own nourishment immediately from vegetables, or from other animals that do so, and which, being returned to the earth, serve for the formation of other similar bodies. These vegetable and animal substances, are the matter from whence Mr. Evelyn thinks the earth derives that clamminess which he takes to be a sure indication of a rich soil.

If the effects of the putrefaction of vegetable or animal substances, when mixed with, and separated in the earth, be duly attended to, we shall find this a very probable

opinion. Vegetables, or animals, if exposed to the air, soon putrify and fly off into the air : but when they are divided into small portions, and mixed with the earth, the earth renders the progress of their putrefaction slower, and intangles the volatile alkaline particles, which would otherwise fly off into the air. These are not only strongly attractive of moisture, but, like the fixed alkali, attract the acid in the air, and effervesce with it ; whence the double advantage of a moist and loose soil.

If we attend to the infinite number of animals and vegetables which are rendered volatile by putrefaction, and fly off into the air ; and to the quantity of perspirable matter from animals and vegetables sent into the air ; and also to the effects of the acid found every where in the air on such substances mixed with the earth ; we need no longer wonder at the efficacy which writers, in all ages, have ascribed to the air, with regard to its quality of enriching the earth.

That the peculiar richness of soils is owing to the putrid or rotten particles mixed with them, is an opinion of long standing. This is Virgil's *putre solem*, rotten, crumbling, or loose earth ; and that which Columella distinguishes by the appellation of *pinguis et putris*, fat and rotten, or fat, loose, and crumbling, as the soil which yields the greatest profit with the least labour and expence, because it is naturally nearest that state which cultivation is intended to effect ; " for to cultivate is no other thing but to open, loosen, and ferment the earth."

From these principles it is that we account for the appearances before-mentioned of good soils, such as, their blackish or dark colour (which is that of all soils in a putrid state) their ready crumbling, easy mouldering, fragrance of smell, &c.

Mr. Evelyn constantly imputes the fruitfulness of the earth to a nitrous salt : but if these rich putrid substances are substituted instead of that salt (and it seems highly probable that he means them) we shall find that his reasoning will appear full as strong, more intelligible, and indeed more rational. The substance of p. 312, and 313, of his Philosophical Discourse of Earth, so far as relates to this matter, will run thus :

" It is this putrid quality which entices roots to affect the surface of the earth, upon which the fertilising rains and dews descend ; which makes all covered and long shaded earth, abound in fertility ; which resuscitates the dead and mortified earth, when languishing and spent by our indulgence to her verdant offspring ; her vigour being quite exhausted, till the rains and showers gently melt into her bosom what we administer to supply that which has been consumed. It is this which fertilises and renders Egypt so luxuriantly fruitful after the inundations of the Nile, &c."

GROUND-IVY, the name of a trailing plant, which strikes out roots from the joints of its stalks : but as it generally grows under hedges, and upon the sides of banks, it cannot be of any great disadvantage to the soil.

GRUB, the name of a large maggot, produced from the eggs of a certain species of butterfly. It is of a large size, and often does great injury to the corn by undermining it, and preying on its roots. It produces the beetle, and is by some called the rook-worm, because rooks are particularly fond of it. The best way of destroying the grub, is good and frequent ploughings, which will clear the ground however infested with this insect, for some years at least. See POTATOES.

GRUBBING, the clearing of lands from the roots and stumps of trees, bushes, &c.

Mr. Worlidge rightly observes, that the best and cheapest method of grubbing up thorny shrubs, broom, grass, &c. is ingeniously delivered by Gabriel Platt. The instrument he has recommended for this purpose resembles a three-grained dung-fork, but much larger and stronger, according to the bigness of the shrub, &c. the stake thereof resembling a large and strong lever. This instrument being placed about half a foot, or any other reasonable distance from the root of the shrubs, &c. and driven to a good depth, with a strong hedging beetle, then raised by laying under it a stone or log of wood, is pulled down by means of a rope fastened to the upper end of the stake, and the whole bush wrenched up by the roots.

GUTTERING-Plough, a small and simple instrument used in some counties for draining wet lands.

It is small, and worked by a single man. A trench four or five inches broad, and six or eight deep, may be easily made with it ; and on that account it is much used for making

ing drains in bleaching grounds, and may do very well for wet clay meadow-land, where the soil is shallow, and apt to produce a large quantity of rushes.

It consists of a piece of iron about five inches broad, and pointed at the end. Upon this piece two other pieces are fixed perpendicular to the former, one on each side, the fore-edges inclining backward; so that the three edges of the instrument form a capital A. To the bottom plate is fixed a socket, for receiving the stale, which is set higher

or lower by means of a wedge on the under-side. At the end of the stale is a cross piece, three feet long, against which the man's breast is placed when he shoves the instrument before him, in order to cut the drain. A rib, twenty-four inches long, is fixed on the socket, and at the end of it a peg, about a foot long and two inches diameter, is fastened to the side of the stale with screws. This peg resteth on the land, when the clod is turned out of the mouth of the instrument.

H.

HACK, a pick-axe, or mattock, having only one end and, that a broad one.

HAIR-STARING (or planted coat), is said of a horse whose hair bristles up, or rises upright; which disorder is owing to being ill curried, not well covered, or too coldly housed.

In order to make the hair of an horse smooth, sleek, and soft, he must be kept warm at heart, for the least inward cold will cause the hair to stare; also sweat him often, for that will loosen and raise the dust and filth that renders his coat foul; and when he is in the height of a sweat, scrape off all the white foam, sweat, and filth, that is raised up, with an old sword-blade, and that will lay his coat even and smooth; and also when he is bled, if you rub him all over with his own blood, and so continue two or three days, and curry and dress him well, it will make his coat shine.

Hair falling, or shedding, from the mane or tail of a horse, is caused either by some heat taken, that has engendered a dry mange there; or it proceeds from some surfeit, which causes the evil humours to resort to those parts.

To cure this, anoint the horse's mane and crest with black soap; make a strong lye of ash-ashes, and wash it all over with it.

But if a canker should grow on a horse's tail, which will eat away both flesh and bone; then put some oil of vitriol to it, and it will consume it: and if you find the vitriol corrodes too much, you need only to wet it with cold water, and it will put a stop to it.

If you have a mind to take away hair from any part of a horse's body, rub it with the gum that grows on the body of ivy, or the juice of fumitory that grows among barley, or boil half a pound of lime in a quart of water, till a fourth part is consumed: to which add an ounce of orpiment, and lay a plaister on any part of the horse, and it will do the business in a few hours.

HALTER-CAST, is an excoriation of the pastern, occasioned by the halter being entangled about the foot upon the horse's endeavouring to rub his neck with his hinder foot.

If your horse is apt to unhalter himself, you must get him a halter with a throat band.

Halter cast is thus: when a horse endeavours to scrub the itching part of his body, near the head or neck, one of his hinder feet entangles in the halter, which by the violent struggling of the horse to disengage himself, he sometimes receives very dangerous hurts in the hollow of his pastern.

For the cure of this, take linseed oil and brandy, of each an equal quantity; shake them together in a bottle till they are well mixt, and anoint the sorance, morning and evening, first having clipped away the hair; but take care to keep the foot very clean.

Another easy remedy is, take oil and wine, of each an equal quantity; boil them together, till the wine is evaporated; and apply the remainder of the oil once a day to the part, which will be quickly healed.

HALTING. A limping, or going lame, an irregularity in the motion of an horse arising from a lameness in the shoulder, leg, or foot, which makes him favour the part, or use it timorously. Halting happens sometimes before, and sometimes behind; if it be before, the hurt must of necessity be in the shoulder, knee, flank, pastern, or foot.

If it be in the shoulder, it must be towards the withers, or in the pitch of the shoulder, and may be known in that he will a little draw his leg after him, and not use it so nimbly as the other.

If he cast it more outward than the other, it is a sign of lameness, and that the grief lies in the shoulder: then take him in your hand and turn him short, on either hand, and you will find him to complain of that shoulder he is lame of, and he will either favour that leg or trip in the turning: also lameness may be seen by him while standing in the stable; where he will hold the lame leg out more than the other; and if when you are upon his back, he complains more than otherwise he does, the grief certainly lies in the withers; so that griping him hard you will perceive him to shrink, and perhaps offer to bite.

If he treads thick and short before, then the grief is upon the pitch of the shoulder, close to the breast, which may be discovered by setting the thumb, and pressing it hard against the place, and thrusting him with it (if you would have him go back), upon which he will shrink, and put back his leg, foot, and body: if the grief be in the elbow, it may be known by pinching him, with the fore-fingers and thumb, and then he will hold up his leg and offer to bite.

But if the grief be in the knee, it may be discovered by the horse's stiff going; for he will not bend it so nimbly as he does the other.

If it be in the flank, or shin-bone, the same may be seen or felt, it being a back sinew, splinter, strain, or the like.

If it be in the bending of the knee, it is a malander, which is also easily discovered.

Farther, when the pastern, or joint, is affected, it may be known by his not bending it so well as the other: and if you put your hand upon the place, you will find it very hot.

If it be in the foot, it must be either in the coronet or sole; if in the coronet, probably it comes by some strain or wrench.

If in the hoof by some over reach, or distemper in or about the frush.

If in sole from some prick, acclay, nail, &c.

HAND, is a measure of a fist clinched, by which we compute the height of a horse.

HAND-WEEDING. See WEEDING.

HANGING-GATES. Mr. Marshall, in his Rural Economy of the Midland Counties, makes the following observation:

"1785, March 27. In Yorkshire, I paid considerable attention to the hanging of gates; not with pivots only, but with hinges; and gained an adequate idea of the leading principle; which, however, I did not commit to writing.

"Here, I have had occasion to apply the principle to practice.

practice. But the true principle had escaped my memory ; a false one having supplied its place : namely, that the only thing needful was to throw the gate out of its upright, so as to learn toward the post ; no matter whether this inclination of the gate were obtained, by the hooks, or the thimbles.

"Led by this false idea, I had conceived that the simplest, and of course the best, way to hang a gate, would be to put the hooks in, exactly perpendicularly to each other, and to give the fall by the thimbles alone.

"In consequence, I prepared a bottom thimble, with a clasp to take the hartree, and with an eye at each corner ; in order that the gate might be occasionally hung, on one or other side of the fence, as the occupation of the inclosure might require, and with this thimble hung a gate.

"The centers of the pins of the hooks being placed exactly perpendicularly to each other, by a plumb line, the gate was hung on. But, instead of falling this way or that, it stood stationarily, wherever it was set !

"Thus finding myself at a stand, without inclination to remain long in so disgraceful a predicament, I set the workmen to other work, and myself to investigate the principles of gate-hanging.

"After musing some time, with the gate in my hand, and sketching my ideas afterward on paper, I saw clearly, and to demonstration, that the fall depends entirely upon the hooks : the axis or motion is given by the situation of the hooks, with respect to each other ; and, which ever way the axis of motion inclines, that way the gate will fall.

"The theory of this principle is easily demonstrable ; but as it requires diagrams to explain it, and is merely elementary, it may appear with greater propriety in another place :—I therefore give, in this, the practical part of the Minute, only.

"A gate should have what is called two falls : one at the post, to make it catch ; and another at right-angle to the gateway, to prevent its standing open.

"The quantity of fall varies with the uses and length of the gate, and the judgment or fancy of the hanger. If a gate has too much fall at the post, it is liable to beat itself to pieces ; if too little, it does not catch with sufficient certainty, and is liable to be blown open by the wind, and thus becomes a deception, rather than a safeguard.

"On sufficient trial, I have found that, for field gates, one inch and a half at the post, and an inch at right-angle, give what appears to me a proper fall.

"With respect to thimbles, the only use of their being made in this or that form, is to counteract the obliquity or crosswinding of the hooks : so that the gate, when shut, shall hang plumb and level ; or every way in a perfectly upright position.

"The way to ascertain the true position of the hooks is that of taking a plumbing line (or any string with a stone tied in it), and, looking along the line of the fence or gateway, drive the hooks, or move the post, until the center of the pin of the upper hook appears, by the line hanging perpendicularly before the eye, an inch and a half nearer the middle of the fence than that of the under one : and then looking along the line of the road (or perpendicularly to the gateway) see that the center of the pin of the upper hook stands one inch nearer the middle of the road than that of the under hook ; observing, likewise, that the pins of the hooks stand, not exactly upright, but in a line with each other, forming one direct axis of motion.

"Gates being liable to sag, or droop, by hanging, they should be hung rather above than below the level.

"The top thimble being usually put into the middle of the hartree, with the eye as near to it as the shoulder of the hook will admit ; the counteraction, of course, depends on the bottom thimble.

"If the bottom thimble be made with two strong straps, to clasp the lower part of the hartree (as it always ought), with an eye on one side, or with two eyes, one on each side, and their centers three inches apart, and with necks projecting, when fixed, one inch farther from the hartree than that of the upper thimble (or, more accurately speaking, with the center of the eye or eyes of the lower thimble standing an inch farther behind the hartree than the center of the eye of the upper one), the gate acquires, on a certainty, the required fall, yet hangs level and upright when shut."

HARNESS-GALLS ; sometimes the breasts of horses are galled by the harness, or rise in hard bunches, especially in rainy weather.

To cure this, first shave off the hair about the sore very close, and rub the whole breast with a lather of water and black soap ; then wash that part of the breast which is usually covered with the petrel, with salt and water, suffering it to dry off itself.

If the hardness of any part of the harness occasions the galling, take it away, or cover it with little bolsters.

HARE, a mist.

HARROW, an instrument for breaking the clods of earth, and covering the corn when sown. It is a sort of wooden drag, made in the form of a square, with large iron-teeth or tines. The reader will find different sorts of harrows described under the articles **BEANS**, **LUCERNE**, &c.

Mr. Marshall observes, that harrowing of wheat in the spring is allowed to bring ketlock and poppies ; he therefore disapproves of harrowing winter crops in spring, unless they are hide-bound, or to remove some particular obstruction. See **FALLOW**.

HART-CLOVER, melilot.

HARVEST, the season when the corn is ripe, cut down, and carried into barns, &c.

Wheat which is full of weeds ought to be cut three or four days sooner than ordinary, that the weeds may have time to wither before the corn become too ripe : for if it be not cut till the grains are full ripe, it will be liable to considerable damage by shedding, loss of colour, and injuries from rain, whilst it remains exposed for the weeds to dry. A single shower, indeed, or even a day's gentle rain, whilst it lies in swarth, is thought to be rather beneficial to the grain, by making it feel dry and slippery, and thresh the better : but all possible care should be taken to guard against its being wetted too much. When, through any unavoidable accident, it is laid up not thoroughly dry, though it will not take much harm in the mow, it will sweat and cling together when laid in a heap after being threshed, and look as white, with mouldiness, as if it had been strewed with flour. Such corn will not keep, and therefore should be sent to market, and sold, as soon as it is threshed.

In Oxfordshire, and several other countries, they bind up their wheat in sheaves, though it be full of weeds, and set three sheaves somewhat sloping against three others, after which they cover their tops with two sheaves opened at their ear-ends, which are extended and placed downward. In this situation they let their wheat stand three weeks or a month in the field, before they carry it in : for no wet can hurt it, nor is it apt to grow in the ear, when thus sheltered.

In their wheat-pooks, as they call them in Wiltshire, the sheaves are set in a circle, with their ears uppermost, another circle of sheaves is placed upon that, and so on, contracting each round, till the pile ends in a point, upon which a sheaf opened, and turned with the ears downward, is placed, like the hackle of a hive ; for an ear turned downward will not grow, though ever so much wet fall upon it, and the bottom of a sheaf being broader than its top, every upper one shelves over the under, like the eaves of a house. A load, or two loads, may be thus put into a pook, which is a very good way to secure corn against rain, and to give the weeds among it time to dry. But, as Mr. Lisle rightly judges, this method is not altogether proper when the wheat is intended to be laid up in a rick ; because, if the weather prove wet, mice will run to it for shelter, and will be carried in with the pooks. It is the general way of making wheat-ricks in the Isle of Wight, without thatching.

Though most corn is bettered by lying awhile in swarth, or grips, to take the dews, which contribute to render its grain plump and of a good colour ; yet its straw becomes thereby the worse for fodder, unless it was cut before it had attained full maturity, and lies out no longer than till it be sufficiently ripened.

In hot dry summers, when the corn ripens fully, and its own vigour gives it a proper colour, and plumps up the grain so that the husks readily yield their contents when threshed, wheat need not lie out in grip, before it is sheaved, or in sheaf ; unless it be very full of grass and weeds : but in cold summers, the wheat is horny and pale, the grains are thin and require being plumped, and their husks cling so close, that they must be mellowed, in order to make them thresh well. The full grain which swells the chaff, even till it opens, in good and fruitful years, lies almost bare to every moisture ; and the heavy ears then spread and hang

hang over the sheaf, which of course opens wider, and lets the rain into the bands sooner than in less kindly seasons, when, the wheat being light, the ears in the shock stand more upright and closer together.

In proportion to the heat of the weather, greater expedition is necessary in reaping: for corn, when hastily ripened, scorched up by the sun, and full in grain, soon takes a stain, is damaged by wet, and easily sheds at every blast of wind. The prudent husbandman should, therefore, in such cases, employ the greater number of reapers; for he cannot desire more than that his corn be perfectly ripe, and of a good colour; for which reason, the less it then lies abroad in grip or sheaf, the better it will be. Cutting it high up, so as to avoid the intermixed grass as much as possible, by which means it is the sooner fit for carting, has been found very serviceable on these occasions; and Mr. Lisle is of opinion that, especially in hilly countries, corn can never be better housed, if thorough ripe, hard, and not weedy, than by gripping and carting as fast as it is cut down; because the dampness which it takes by lying on the ground all night, is not easily removed.

It is always most advisable to turn the grips of wheat which is left out, very early after their being cut down, in order to get them dry as soon as possible. By this means they are kept the longer from sprouting in the ear, in case of rain: for if dripping weather or driving mist should ensue, and continue for any time, after they have been already loaded with wet, all the art of man cannot prevent their growing: nay, even independent of other accidents, the bare weight of the ears will sink the grips of wheat to the ground, though they have been laid ever so light and hollow; and they will certainly be injured thereby, if suffered to lie long out in wet weather. The best method of guarding against this, is by laying them in triangles, as directed by M. de Lisle.

A principle somewhat similar to this seems to be the reason why the farmers in Leicestershire, and Northamptonshire, in particular, where the land is rich, deep, lies flat, and is much inclosed, leave a very high wheat stubble, upon which the grips are supported, lie the hollower from the ground, and consequently are the easier dried by the sun and wind; for it is to be observed, that the fatter and richer the soil is, the sooner the grips will grow after they have taken wet, if they lie upon the naked ground; much sooner than they would, in the same case, in a hilly country where the land is poor. Husbandmen there besides esteeming it an advantage that they can stow a greater number of short-cut sheaves in their barns, think the loss of the straw compensated by the excellent thatch which they make of the stubble. In some places they mow it for drying malt.

The forwarder the harvest is, and the warmer the season, the longer the corn may safely lay in the field, either in grips, or sheaves: for this exposure to the air, after it is cut down, mellows it, and makes it thresh better and look finer. Thus, when the wheat-harvest takes place by the middle, or at least before the latter end of July, of which we have had instances, there can be little danger in letting the wheat lie abroad four or five days or a week, if it be not over ripe when cut, even though a rainy day or two should come: for at that time of the year the sun is so hot, the days are so long, the grass so short, and the dews generally so little, that the corn soon dries; even after a hard shower; whereas in the middle, and still more towards the latter end of August, the rainy season frequently begins, the dewy nights grow so long, the grass is so rough, and the sun's drying power so much abated, that, if wet weather comes on then, the corn will be much more apt to grow.

A caution which Mr. Lisle recommends as singularly important in hilly countries, is not to bind the grips of wheat up into sheaves too early in the day; because, in such a situation, the grips take so great a damp by having lain on the ground, that, though the straw, and chaffy ears may seem to be dry when the dew is first gone off, and after the sun may have shone an hour or two upon them, yet there will remain an inward dampness in the corn, and within the straw, which, if laid up in that condition, will come damp from the rick or barn at threshing time. The afternoon is therefore certainly best for gripping and binding into sheaves in such countries, but so that this work may be finished before the day is over. The bands should, however, be laid in the morning, that they may not crack;

for the straw will not twist after the sun is up, but will be brittle, and break off below the ears. The turning of three or four of the stubble or bottom ends of the straw to the ears of the band, helps greatly to add to its strength and toughness.

The bands for binding up the sheaves should not be spread but in fair weather, because, being pressed down by the grip or two which it is necessary to lay upon them to keep them in their places and prevent their being untwisted by the sun, they will grow sooner than any other corn, if rain should come; for they cannot dry, on account of their lying undermost. But though the bands must always be made while the morning dew is upon them, the sheaves ought not by any means to be bound up wet, if they are, they will certainly grow mouldy.

Farmers do not always attend sufficiently to the binding up of their sheaves, but suffer the reapers, for dispatch, to tie the bands just underneath the ears instead of binding them at the other end; the consequence of which is, that they will hardly hold together to be flung into the cart at harvest, and will certainly be in great danger of falling to pieces before they are threshed.

If a little rain is foreseen in harvest-time, it is best to bind the grips up into sheaves as fast as they are made; because small showers will wet the single grips so much that they cannot be bound up, and those showers may be the fore-runners of greater rains. The sheaves, being bound, will soon dry after such wet. But if a hard rain is foreseen, the best way is not to bind up into sheaves, because they will then be wet to the bands, and must all be opened again. One of Mr. Lisle's neighbours, to whom this happened, unsheaved some of his wheat to dry it, opened it, and turned it so often, that the ears broke off, by which he lost half his corn. Caution ought therefore to be used in this case, lest by curing one evil we create a worse.

All farmers agree that rain which comes with a driving wind, is the worst of any weather for sheaves of wheat out in the fields; and that it is worse than a downright soaking rain for such sheaves as are wet to the bands.

In a wet harvest, small sheaves are best, because, thin at top, and falling close, the rain does not sink down into the middle of them, and so go through into the bands, as it is apt to do in great sheaves, which lie broader, and take a larger compass. Small sheaves are also best when many weeds are intermixed with the corn, because the air, wind, and sun, have then a greater power to dry them, than they could have if the sheaves were large.

It has been the opinion of some good farmers, that if the weather be likely to continue fair, it is best to lay the sheaves, the night after the wheat is cut, one by one, flat on the ground, in order to make the straw lie the closer together, and their ears stand the stiffer, and more upright, by which means they will be less apt to open at the top, and rain will have the less power to penetrate them when laid in shocks.

Mr. Marshall, in his Minutes of Agriculture, recommends the tying of sheaves but loosely and not too large; but the extreme must be guarded against; for if they be tied too loosely there is danger of their slipping wholly out of their bands; besides their being difficult to load, and worse to stack. He recommends also that they be set up in such a manner, as but just to touch each other at the butts and ears; leaving a space of a foot and a half between each sheaf at the band place, and that the ears of the bands be turned inward. He observes in general, that the small, loose-tied sheaves will dry soon, while the large tight-tied ones, of the same shock, will grow; and that the ears of the bands are the first that will grow; and that those shocks which stand free and open, far better than those of which the sheaves stand huddled together in a close lump, through which, neither air or sun can penetrate. Instead of tying the band at the foot of the butts, he recommends the tying them loosely about the same distance from the tips, and spreading the butts, setting the sheaves up singly in resemblance of sugar loaves, leaving the insides totally hollow; this will enable them to dry very soon; and then shifting the bands the next day back again to the common banding places, and opening the ears, they will soon be perfectly dry." In his Rural Economy of Yorkshire, Mr. Marshall observes that, "nine-tenths of the corn that is cut with the sickle in this kingdom is cut by men. In Surry and Kent a woman may sometimes be seen with a sickle in her

her hand. In Norfolk it is a sight which is seldom or ever seen. Here, it is almost equally rare to see a sickle in the hand of a man; reaping (provincially, "shearing") being almost entirely done by women.

Three women and one man make a sett; who, of a middling crop, do an acre a day. If corn be thin, a man will bind after four women; if very thick upon the ground, he requires a boy to make bands for him.

Sometimes the bands are laid for the women to throw their handfuls into; but in general they lay the corn in "reaps," of about half a sheaf each; the binder gathering it up carefully against his legs in the manner wheat straw is usually gathered on the threshing-floor. This is much the best way (though somewhat more troublesome); the corn being by this means bound up tight and even, and the sheaves made of an equal size.

The day-wages of a woman in harvest is 10d. of a man 2s. Thus wheat, which in Surry would cost 10s. to 12s. and which, in any country I have observed in, would cost 7s. or 8s. is here cut for 4s. 6d. an acre."

Reapers should take care in placing their grips; to lay the straw end in the furrow, and the ears out; because these will then stand sloping up, and lie tolerably dry, even though rain should come; but in the other way they would soon grow.

Mr. Lisle remarks, in his *Observations* (which might have been thrown into a more regular, as well as more laconic form, before they were published; for that gentleman certainly never intended, that his unconnected notes and memorandums should appear in the manner in which he penned them merely for his own use) that "one of his reapers, when he had made up some wheat into sheaves, the wheat being long-eared and top-heavy, said, rain had not need meet with those sheaves before they were carried home." Mr. Lisle asked him, "Why so?" To which the other replied, "because the ears being long and heavy, were busled-headed, that is, did hang their heads downward into the sheaf, so that (in case rain should run down to the bands) neither sun nor wind could enter in to dry them; whereas, said he, when the ears are short, and not heavy, they stand upright and hollow, so that the sun and air may easily dry them."

The straw of blighted wheat, being hollow and spongy, is very apt to imbibe moisture; for which reason the best way is to house such corn as soon as it is tolerably dry, especially if there be the least prospect of rain; for if straw of that loose texture should once soak in wet, and showery weather should afterward come on, it would require much more time than other corn to dry and fit it for threshing.

Experience has shewn, that wheat keeps better when stacked in the ear unthreshed, than its grain does alone, when threshed out and laid up in granaries: besides which, a farther advantage which attends the stacking of this corn is, that the husbandman need not thresh it, but as his markets or other occasions require; whereas, if it were to remain long in the barn, he would not be able to preserve it from rats, mice, and other vermin, which harbour in the walls, roofs, &c. of such buildings.

To guard against these enemies, as well as against the dampness of the ground, which would otherwise occasion great loss (for there have been instances of its rotting piles of corn to the thickness of a yard, or more) four, six, or more strong posts, according to the intended size of the stack, are driven into the ground, beams of a proper strength are laid across them, and upon these is made a floor to support the stack. Some farmers build these platforms for their stacks so high from the ground, that there is room to shelter their carts and other implements of husbandry under them: and some again, as an additional security against rain and birds, erect sides and a roof, by which means they form a kind of barn: but this is needless, if the corn be stacked, as it ought to be, in sheaves, with the ears turned inward, and the straw ends outward, and the top well thatched with good wheat straw, which is the best of any sort for thatching. They likewise cover the supporting posts with tin, for about a foot in breadth from the top, to prevent the mice and rats getting up: but this method soon proves ineffectual, because tin is very apt to rust, and consequently loses its smoothness. A better way, as Mr. Mortimer advises, is to cover those posts with Dutch tiles, such as chimnies are commonly set with, because they will always keep smooth. Others make their supporters of two hewn stones, one of which, being about three feet high, and sloped from the bottom, where it is two feet wide, to

the top, where it is but a foot thick, stands upright, and is covered with a large flat stone, about a yard square, or which is better, of a round form. This not only prevents rats and mice from climbing up, but is also a security against the dampness of the ground. Others again, whose method is the best of all, lay a foundation of brick as wide as the stack is intended to be, and build round it a brick wall, about two feet high, capped with hewn stones, which project sufficiently outward, to hinder the ascent of any sort of vermin. If either rats or mice should, by the help of any thing accidentally rested against the stack, chance to climb up, and get into the corn, they will not be able to remain there long, because, as they cannot live without water, necessity will force them down, and their former means of climbing being removed, they cannot get up again. If any of them chance then to be left in the stack, they will soon die there for want of drink.

Particular care should be taken in the stacking of wheat, always to lay the ear ends of the sheaves inward, and upon a rise, so as to keep the middle of the stack full while it is worked up: for in this case, when it settles, the sinking will be chiefly on the outside, which will thereby be made to lie the closer, and the straw ends being outward, and inclining downward, birds cannot get at the grain, nor can rain be driven up to the ears. The shortest and thinnest sheaves should be used in the topping of the stack, because it cannot be so conveniently drawn in and narrowed with great long sheaves. They should be taken from off the same ground, if the husbandman wants to keep any particular sort or growth of corn pure and unmixed. Where less nicety is observed; oats, or some other kind of coarse grain, are frequently laid on the top of the stack of wheat under the thatch, the better to preserve it from being wet. Wheat, properly stacked, will keep in perfect order for many years.

Mr. Lisle, who does not approve of stacking any corn but wheat, when room can be found for it in the barn, thatched a long rick of vetches, brought up sharp, with barley straw, to the thickness of three feet, and yet found, upon cutting it, that the rain had penetrated through this thick covering, and done considerable damage to the vetches. He imputes this, first, to barley-straw's being more woolly and spongy than wheat straw, which is close and hard; and, secondly, to the stack's having sweated and heated pretty much, in which case the covering of straw is always hollowed and softened, and consequently rendered the more apt to admit and retain wet.

The stalks of oats are naturally so smooth and slippery, that they are apt to slide in the stack, which then frequently tumbles down, especially if this corn was very dry when carried in. An oat rick must therefore not be widened by any means beyond its foundation, which generally is of faggots, nor should its sides ever bulge out, but, on the contrary, they should be gradually contracted. Barley, having a rough stem, may be piled more upright.

When sparrows roost at night in holes, under the eaves of a stack of corn, it is reckoned a sure sign that there are neither rats nor mice in the rick; for their squeaking and running about in the night, would disturb the birds, so that they would not stay there.

Mr. Marshall, in his *Rural Economy of the Midland Counties*, on the subject of *Harvesting*, says as follows:

"The corn harvest of this district, though it cannot be called, emphatically, a corn country, is not got in without some foreign assistance, from whom are termed 'peakrills' and 'low country men'—namely, men, and some women, from the Peak of Derbyshire, and the Morelands of Staffordshire. The wheat is much of it cut by these itinerants.

"The harvest labourers of the district are not hired for the harvest month, as in Surry, &c. nor for the harvest, be it short or long, as in Norfolk; but work by the day, as at other seasons of the year; and for the same wages, a shilling a day; but with the addition of full board, so long as the harvest lasts: and, in addition to this, each labourer who has been constantly employed through the summer, has a right, by custom, to the carriage of a load of coals, in autumn. It is also a pretty common custom for farmers to let their constant labourers have their bread corn somewhat below the market price; more especially when corn is dear.

"The hours of work, too, like the wages, are the same in harvest as in less busy seasons; and the same slow pace is too generally observed. No coming at four in the morn-

ing; no trotting with empty waggons; nor any personal exertion, whatever, betokening harvest; saving such as are stimulated with ale as strong as brandy!

"The method of harvesting sheaf corn, whether wheat or oats, is, in this district, above par. In part it is new to me: reaping being generally done by the "threave:"—feldom by the acre.

"A threave is twenty-four sheaves; each sheaf measuring a yard round, in the banding place; the string crossing the band in measuring. A better sized sheaf, for seasons and crops in general, could not, perhaps, well be fixed upon. See WHEAT.

"The great difficulty, in reaping by the threave, lies in not being able to get the sheaves made up to the standard. The deviation, however, is on the right side: whereas, in reaping by the acre, it will always be on the wrong. For, in that case, it is the interest of the reapers to make large sheaves; having thereby fewer bands and less binding. On the contrary, in reaping by the threave, it is their interest to make small sheaves.

"Another conveniency arises from reaping by the threave: any number of hands may be scattered over a piece of corn, as circumstances may require, without the extraordinary trouble of measuring the land in this case. Each man sticks to his "threo," whether it consists of one or more lands, and sets up his own sheaves in one row of shucks, of twelve sheaves each: so that the trouble of ascertaining the number of threaves is inconsiderable.

"The price, for wheat, is fourpence a threave, with beer; provided the crop be tolerably good: if very thin, five-pence or six-pence is sometimes given: or such thin wheat is sometimes reaped by the acre; at about six or seven shillings an acre. For oats, three-pence is the common price.

"In carrying sheaf corn, there is usually a loader to each pitcher. The butts are laid outward all round, as in Surry and Norfolk; forming the load, not into a long square, but into a figure between that and an oval; binding it across and across, in three or four places.

"The method of harvesting loose corn, whether oats or barley, is reduced, here, to the lowest degree of simplicity.

"In Yorkshire, barley and oats are mown inward, against the standing corn, and harvested in sheaf.

"In Kent and Surry, they are mown outward, with a cradle, laying them so straight and neatly, they might be bound after the scythe; but are harvested loose. In cocking them, the Kentish farmers make use of corn forks; laying the ears all one way; preserving the same neatness and regularity, even to the stack: the outside course of which is laid with unbroken pitches, with the butts outward, having thereby a security nearly equal to that of sheaf corn.

"In Norfolk, they are mown outward, with bows, fixed to the heels of the scythes; which, however, do not lay them so neatly as cradles; but still the heads, if the crop stand any way fair, lie one way, and the tails the other. There, too, the corn-fork is used.

"Here, they are mown outward with naked scythes; and cocked, or rather rolled into rough bundles, with common hay forks; and this, generally, two or three days before they are carried: a crop of clover, a crop of barley, a crop of peas, a crop of oats, and a crop of beans and vetches, being harvested very much in the same manner.

"Mowing barley and oats with naked scythes, and pulling them about with hay forks, have, to strangers, a slovenly and wasteful appearance. But with respect to cocking loose corn before the day of carrying, something, perhaps may be offered in its favour."

"It is true, that, in other districts, it is considered as very bad management to leave even a few cocks remaining only one night; under an idea that, if loose corn once get wet in cock, it is difficult to get it dry again, without a great waste of labour and corn. Nevertheless, experience shows that even a very heavy shower has not that evil effect in the practice of this country.

"An incident in my own experience convinced me of the fact: I had, through neglect, a few oats in cock left out all night. Next day, much rain fell; but the succeeding day proving fine, they were got into very good order again, in this manner. The tops were first dried, by raising them up, light and porous, with the tines of a fork; so as to let the sun and air into them; and, when the tops were dry, the bundles were turned over to air the bottoms.

"In this manner, and without greater trouble, corn cocks generally dried; though sometimes it will happen that

they require to be pulled to pieces: in which case, there is, of course, considerable waste.

"The Midland farmers have one very good plea for harvesting oats in this manner. For, by cocking them a few days before carrying, the labour and waste of turning is saved: besides, by being cocked while a portion of the sap remains in them, they are not so liable to be shed in cocking, as when they are disturbed in a dry parched state.

"This practice, probably, took its rise in open common fields. Formerly, much of the district lay in that state; the soil being raised into high roof-like ridges. The furrows and skirts of the lands lay, of course, proportionably low; and the corn being thereby frequently deprived of the benefit of the sun and wind, it was found, by experience, most eligible to gather the corn into heaps, and place them upon the top of the ridges. And this is the present practice of "field farmers." In a few days after cutting, the whole crop may be seen standing in pitchcocks, placed in close order, like strings of beads stretched along the ridges.

"But notwithstanding this practice may be eligible where corn is mown with the naked scythe, and rolled up into rough porous bundles, it does not follow that it should be universally adopted. Were a Kentishman to leave his unruffled close piles exposed even to one heavy shower, he would find some difficulty to get them thoroughly dry again, without spreading them abroad.

"An evil attendant of the Midland method of harvesting loose corn is, the increase of bulk which corn harvested in this way acquires, comparatively with the same quantity of corn harvested in the Kentish manner. More barn-room is of course wanted, and a greater number of loads are to be carried. Four loads an acre is no uncommon crop; five loads are talked of, and are sometimes carried. But the method of loading, and that of barning, both of them tend to increase this evil.

"The method of carrying loose corn here, differs from that of other districts, in having only one loader to two pitchers; and in loading, not with the arms, but with a fork; the loader standing in the centre of the load, and piling the corn loose and light around him. Thus the entire process tends to increase the number of loads.

"And the method of housing is not calculated to do away the inconveniency. I never met with an instance, in this district, of a horse, or any other animal, being used on a mow.

"Ricking, however, remedies the evil; and in this district, where barn-room is more contracted than in some others, loose corn is pretty generally put into ricks.

"In the method of ricking loose corn, nothing is noticeable; excepting the last finish. To endeavour to secure the stems from the pillaging of sparrows, and other small birds, they are, generally, either "tucked" or "pared:" that is, either the loose ears, exposed on the outside, as many unavoidably are, in the method of harvesting above described, are doubled back, and thrust into the stem; or the entire stem is shaved with a scythe laid longway in the handle, or some other similar instrument: in some few instances, I have seen the stems thatched, as the roofs.

"On ricking sheaf corn, a few particulars may be mentioned. Though built on a square frame, the stem—provincially the "wall," is not carried up square, as in Surry and Norfolk; nor round, as in Gloucestershire; but in a form between the two; the corners of ricks being rounded off, as those of loads.

"Large ricks being fashionable, and it being customary, in carrying up the stems, to bind with the ears, instead of the butts of the sheaves, they are of course liable to slip. This has taught the Midland rickers an admirable expedient, when any symptom of slipping, in carrying up the stem, is perceived, to prevent the mischief; namely, that of laying long green boughs across the part affected: an excellent thought.

"In setting on the roof of a sheaf corn rick, the Midland rickers are above par: laying the last course of the stem so as to project a few inches, and form a kind of cornice for the eaves of the thatch to rest upon, and to carry the drip clear to the stem. The middle is then filled in full and round; so that the butts of the outside sheaves hang downward.

"This, though not peculiar to the district, is a rule which ought always to be observed, in forming a roof; for, in this case, if rain should happen to penetrate through the thatch, there is little fear of its doing, even the roof of the rick much injury; every straw becoming a conductor to lead it to the surface.

"Another

"Another commendable practice, in forming the roof of a sheaf corn rick, and which is new to me, is that of carrying it up without a pitching hole. A man sticks his heels into the roof, and stands with great ease and safety. This might well be copied by other districts: holes are dangerous; unless great care be used in making them up, and in thatching them securely. For if water enter, in this part, it finds its way directly into the heart of the rick.

"The method of securing corn ricks, in a catching season, previous to their being thatched, is likewise entitled to notice. It is effected with "battins"—small trusses of straw—which are afterward used as thatch. A row being laid close and pegged securely along the eaves with their butts downward; others are laid (firmly, but without pegs), as tiles or slates are laid on a roof, with their heads downward; spreading the ears (without untying the bands) so as to prevent the rain water from getting through between those which lie below: continuing, thus, till the ridge be reached.

"Having plenty of these battins, in corn harvest, ready at hand, to cover a rick with, in catching weather, is a very great convenience. A rick of 200 threave, eighteen or twenty loads, may be secured in a few hours: or, with plenty of hands, in half an hour.

"The method of thatching ricks is also peculiar in this district, and requires to be mentioned. Instead of thrusting the ears of the straw into the roof, and spreading the butts outwardly as a security; the straw, in thatching, is laid on as the battins, with the ears downward, and of course outward (excepting the first course at the eaves), and is secured in its place, by pegs and hay ropes; passing horizontally from end to end of the roof; at the distance of twelve or fourteen inches from each other.

"Sometimes thatch is bound with ozier twigs, which are much more lasting than hay bands (that are only annuals), in a simple ingenious manner. The small end is formed into an eye, like that of a with, and the thick end run into the roof as a peg, through the eye of the succeeding twig.

"An inconveniency attends this method of thatching. A rick cannot be thatched with propriety, until the roof has done settling. For if it settled after it is thatched, the straw is raised into puckers between the bands, and the water of course, let in."

In his Rural Economy of the Vale of Gloucester he says, "the work of harvest was, formerly, done chiefly by harvest-men; but now, in part, by the acre.

"The wages of harvest-men are thirty shillings for the harvest; or a shilling a-day; with full-board.

"The method of victualling harvest-men, in this district, is singularly judicious. They have no regular dinner. Their breakfast is cold meat. Their refreshment in the field, bread and cheese, with six or eight quarts of beverage. At night, when they return home, a hot supper; and, after it, each man a quart of strong beer, in order to alleviate the fatigues of the day which is past; and, by sending him to bed in spirits and good humour, to prepare him for the morrow's toil.

"There is more than one advantage arises from this custom. All work within-doors, in the middle of the day, is got rid of: and the advantage of continuing the work of the field, without a break through the prime part of the day, is obvious; and is highly estimated by those who know the value of it from experience.

"The hours of work are long;—from dawn to dusk;—especially when dispatch is more particularly requisite. The quantity of work done is above par: namely twenty or thirty loads of corn; with one set of men."

HASK, a husky cough.

HATTOCK, a flock of corn, consisting of twelve sheaves.

In some counties it implies only three sheaves laid together.

HAVER, a name given to oats in some parts of England.

HAUNCH or HANCH; the hip part of the body of a living creature.

The haunches of a horse are too long, if, when standing in the stable, he limps with his hind legs farther back than he ought, and that the top or onset of his tail does not answer in a perpendicular line to the tip of his hocks; as it always does in horses whose haunches are of a just length.

There are some horses, which though they have too long haunches, yet commonly walk well; such are good to climb hills; but to balance that, they are not fit to go down a

descent; for they cannot ply their hams, and they never gallop slowly, but almost at full speed.

HAW, a close, or small field.

HAW, is also the common name for the fruit of the white thorn.

HAW likewise signifies the swelling of a spongy texture, growing in the inner corner of the eye of a horse, and sometimes so large, as to cover a part of the eye.

HAY, a general name for any kind of grass, cut and dried for the food of cattle.

When grass is to be made into hay, the farmer will be directed in the season for mowing it, by the quality of the grass. When the crop is very great, it should be cut as soon as the bottom of the grass grows yellow: for if it stands longer, more will be lost by the quantity of leaves rotted at the bottom, and the ill flavour which these will give to the rest, than will be gained by its growth. When other circumstances permit the choice of time, it should be when the grass is in full bloom before the stalks begin to harden, and rather early than late, because the same sap remains in the roots, the sooner the next crop will spring up. There is not, however, any general rule for this; because, in some cases, the ripe seeds add a great value to the hay, as in saintfoin and burnet: and in others, the growth of the grass itself brings a recompence, as in the fowl-meadow grass.

A dewy or dusky morning should be chosen for cutting the grass because being then fullest of sap, it stands best to the scythe. When the high noon-tide sun has dried the grass, and made it recline its head, the mower will employ his time more usefully in making the hay already cut, than in continuing to mow, with great additional labour, grass, which no longer makes the due resistance.

Our farmers in general are very inattentive to the management of their hay whilst in the cock, to which is in a great measure owing the loss which they (or rather the nation) sustain every year, by the damage which the hay receives from rain.

To guard as much as possible against this accident, let the hay-makers follow the mowers, and if the weather be quite fine, spread out the grass as fast as it is cut down, especially if it lie so thick in the swarth, that neither the air nor sun can pass freely through it: but if wet be feared, let it remain in the swarth. At night, make it into grass cocks, and the next day, as soon as the dew is off the ground, spread it again, and turn it, that it may wither on the other side; then handle it, and if you find it dry, make it up into large cocks. If the weather continue favourable during the second day, the grass will, by that time, be so dry as to bear being kept in these cocks till the day on which it is to be carted, when it should be spread out again in the morning, to receive a farther drying, if wanted. If these cocks are made as tall and as taper as can be, consisting with their standing safely, the winds, by passing through them, will dry them gently and equally; and though rain should fall upon them, it will not do much hurt, because the greatest part of it will run off directly, and the sun and wind will soon dry that which may have penetrated into the cocks. These cocks have therefore a great advantage over the common small and low ones: for if a rainy season comes on, these last will be so thoroughly wetted, that the wind will not be able to pierce sufficiently to dry them. More hay is, perhaps, lost for want of making the cocks properly, than by all the rains which happen in the hay-making season.

Where the colour of hay is principally regarded, as in London, the best way of making it, provided the weather be fair, is to open it perfectly and spread it thin, immediately after it is cut, and to have hands sufficient to turn and shake it, till the evening, when it is made up in grass cocks; and thus proceed every day till it is sufficiently made. In this way the hay retains a fine green colour, and gives it a value with the buyers of hay for horses; and for this reason the hay made about Hendon, in Middlesex, and which is made in this manner, gives it a value in London, though in other respects not superior to the hay from some other places.

Such hay, however, is not more nourishing to cattle, than other hay of equal quality, made in a different manner. Some are apt to blame the farmers, for negligence or ignorance in the management of their hay; but it is a matter of greater difficulty than they seem to be aware of. In catching seasons, it requires much attention and industry to save hay, and after all is liable to be spoiled, or greatly damaged

to the owners great loss, notwithstanding his utmost care and anxious attendance upon it; and in fine weather, by a sudden change, he may suffer as great loss, as in a catching season. I had once a large field of hay, in fine order, and set up in hay cocks; the weather then altered to rain, attended with such a high wind, that the hay cocks were blown down, and some of them carried above twenty yards from the places where they stood; so that the field was covered with the hay, and the weather continuing showery, the hay could neither be dried nor put up again as before. It was therefore raked together, and made into very small cocks, which could be readily turned with prongs; this was done several times when the rain abated, and was sometimes necessary to be done even in the rain to prevent its fermenting: this hay was at last saved at a great expence in tolerable order, though much damaged; and is mentioned here as a good method of saving hay in general, to put it into these very small cocks soon after it is mowed, not to be spread at all, if the weather is the least suspicious; and by opening the cocks sometimes when the weather is fair, and frequently turning them, the hay may be well made: though it is well known to all experienced husbandmen, that saving hay in good order, is often a business of much difficulty, and attended with no small expence and trouble.

The method here recommended is confirmed by the experience of a New England husbandman, whose account of it to the reverend Dr. Elliot ran thus:

"I shall relate to you my own practice in making of hay, though it may seem small and trifling at the first mentioning: but finding that it saves me near two fifths of the time and labour I used to be at in this article, and that my hay is, I think, better than when I used to pursue the usual method, I esteem myself justified in communicating it to the public. My method is this: I mow my grass, and let it lie in the swarth till the dew is off the next morning: then I turn and spread my hay, and let it lie in the sun till the after part of the day, when I take it up and cock it well, and never meddle more with it, till I cart it into my barn, or stack it. If the weather be good, it will do well to cart after it has stood two days in cock. This, I have found by five or six years constant experience, answers for any sort of hay, except salt-hay and red clover, of which last I have not had so long trial; but with respect to clover hay, I managed it last summer after this manner, viz. I followed my mowers as they cut the grass, I spread it as thin as I could, and before night I put it in cock. The next day, after the dew was off, I spread it again; in the afternoon, I cocked it a second time, and meddled no more with till it I carried it. The appearance of the hay since, makes me judge that no man has better of the sort. My first coming into this practice was purely accidental. After cutting my grass, five or six years ago, I put it in cock the next day: but my avocations then were such, that I had no time in which I could possibly take any farther care of my hay for many days. When I had dispatched my other affairs, I returned to it, and found it in as good order (that is to say the bulk of it) as ever I had hay in my life. Reflecting then, how much labour may be saved by this method, I have followed the same practice ever since, and find it answer very well. The reason why I think my hay really better is, because I take it for granted, that the more juice or natural moisture we can retain in it, without corrupting and rotting the stalk, the richer and more nourishing it is. The too often turning and spreading of hay in the sun extracts too much of the richness thereof; and one day's thus lying will take away such a quantity of the most watery particles, as that the remainder is only sufficient to raise a proper fermentation thereof when in the cock, while the smallness of the body there keeps that fermentation from rising to such a height as to corrupt it. After twenty-four hours, the fermentation will gradually abate: and the pitching of the hay into the cart, and afterwards into the mow, or stack, so checks it, that it will not again rise to such a height as to be detrimental. Cattle are fonder of this hay than of that which is made in the common way, and less of it will support them."

It would be almost needless to observe, that no narrow wheels should ever be brought upon pastures, not even in the driest season of the year, as that of hay-making generally is. The advantages of broad wheels, which help to roll and level the ground, and render the draught much easier, whether on grass, or any other soil in which narrow wheels will sink, have been confirmed by experience; and are as self-evident as it is that the latter crush and

bury, and thereby destroy great numbers of the plants of grass, wherever they are dragged.

If the hay has sweated a little in the cock, there will be the less need for its sweating afterwards in the rick, where it will then lie so much the closer, and consequently keep the better.

Mr. Marshall, in his Minutes of Agriculture, says, that having a field of hay that had been cut almost a fortnight and was in tolerable order; the sap being nearly exhausted; yet the weather was very unfavourable, but he was unwilling to expose it any longer in this critical state; he therefore put it upon the waggons to keep it out of harm's way; but did not unload it immediately, letting it remain until the next day, when he unloaded one of the waggons on to the stack very gently, and left it untrodden. On to the emptied waggon reloaded another which stood in the field. The wind was high, and the sun hot: two men reloaded it as deliberately as possible; breaking every lump and loading it lightly with a fork: they were three or four hours in doing it. It was unloaded the following day in good order. In this manner, he proceeded with the remainder, and with the same success. By thus exposing it to the sun and wind, and by leaving it on the stack for twenty-four hours untrodden, it was got from tolerable to very good order. Because hay, which had been long cut, and whose juices are exhausted, is loaded on the waggons to prevent it being totally spoiled; it surely does not follow that it should be hurried into stock wet or dry. Perhaps hay not half made, might, by repeated reloading, during fair blasts, be well got, even in very bad hay weather, as frequently happens.

Suppose one load takes two men three hours and a half; two men would reload three loads a day: about $13\frac{1}{2}d.$ per load. Ten times $13\frac{1}{2}d.$ is not equivalent to the difference between good and bad hay. Re-making in large cocks, may help hay which is under-made; but a cock cannot be drawn into a barn, or under a shed as a cart or a waggon. See *Tare HAY*.

He says also that, perhaps, meadow hay is generally cut too early, and the first crop of clover too late; that is, such grass as is intended to stand for a second crop, should be cut early that the second crop might not be caught in the autumnal rains; and that which is cut but once should stand until it be fully matured, that it may not shrink in making, that the hay may be heartier, and that it may be made with less labour and less risk. He recommends to cut clover the first and second weeks in June, and meadow hay the second and third weeks in July, for although grass seems to shrink on the ground before cutting, the quantity of hay is not the less when it comes to be carried into the stack, nor the weight less when it is cut out.

Mr. Marshall, in his Rural Economy of the Vale of Gloucester, says, that "The age, at which a crop of grass ought to be cut, is a subject of no small importance. In the ordinary practice of this district, as in that of every other, which I have observed in, grass is suffered to stand much too long before it be mown for hay.

"This evil practice may have originated in common meadows, whose after-grass is unstinted, (or frequently belongs to a separate owner): a species of mowing ground, which, formerly was common to this and most other countries.

"There are, however, in this district, men who are well aware of the advantages of early cutting; who know, from experience in *grazing*, the value of the after-grass of early mown grounds; as well as the fattening quality of hay, which has been mown in the fullness of sap. Hence we find in this country, more advocates for early cutting, than in most others, where the fattening of cattle on hay is not a practice. There is, in an ordinary season, much grass cut, in different parts of the district, at *six or seven weeks old*.

"In *mowing*, it is observable, the Gloucestershire labourers cut remarkably level. In some cases not a stroke, or scarcely a swath-balk, is discoverable. This is chiefly owing to the narrowness of the swath-width, and the shortness of the scythe in use in this country. The mowers of Gloucestershire and those of Yorkshire work in opposite extremes of the art. The Yorkshireman drives a width of nine or ten feet before him, the Gloucestershireman of six or seven feet only. I have measured across a series of swaths which one with another, have not measured six feet wide. The one makes the operation unnecessarily laborious, and causes, almost unavoidably, a waste of herbage,—the other renders it unnecessarily tedious. A good workman may take

take *half a rod* (eight feet and a quarter) with sufficient ease to himself, and at the same time leave his work sufficiently level. It is prudent, however, on the part of his employer to see that he keeps within due bounds; and, generally, that he does not exceed the *medium width*.

"The *making* of hay is an inexhaustible subject. Every district, if we descend to minutiae, has its shades of difference. The practice of this district resembles very much the practices of Yorkshire; not only in the first stages, but in the remarkable expedient of forming the hay into *stacklets* (here called "*windcocks*") previous to its being put into *stack*. But the practice is here carried a stage farther; the hay being sometimes made into small *stacks*, of several loads each in the *stack yard*; and, while yet perhaps in a degree of heat almost suffocating to work among, is made over again into one large *stack*.

"The same reasons are given for this practice, here, as in Yorkshire: namely that of being able to make it fuller of sap in this way than it can be by the ordinary method. There seems however, to be an additional motive to it in this country: namely that of being enabled, by this means, to make it into *very large stacks*, of fifty or perhaps a hundred loads each. Such *stacks* are fashionable. They are spoken of with pride: and it seems probable that the *pride of great ricks* has some share, at least, in the practice of giving hay a double heat.

"Be this as it may, however, it is a fact, well ascertained, that the hay of these Vales is of a superior quality. It is found to bring on fattening cattle nearly as fast as the green herbage from which it is made, passing through them with the same appearances. And the produce of butter from hay in this district, is extraordinary. But whether this superior quality be owing, in part, to the method of making it, or wholly to the soil and the herbage from which it is made, is by no means well ascertained. That there is a something in the soils of these Vales which gives a peculiar richness to whatever they produce, is to me evident; and to endeavour to preserve in hay as much as possible of this richness is, indisputably, good management.

"The degree of heat, which hay ought to be subjected to, is an interesting subject, which is seldom agitated, and little understood; even in this country where some little attention is paid to it. Something may depend on the species of stock it is intended for. The prevailing opinion, here, seems to be that, for fattening cattle, it ought to be moderately or somewhat considerably heated. For cows, however, there are dairymen, who say it should have little or no heat; giving for a reason, that "heated hay dries up their milk."—These, however, I mention merely as opinions. They may be well grounded. If not, they may excite a spirit of enquiry into a subject of some importance in a grassland country."

Mr. Marshall, in his *Rural Economy of Yorkshire*, says that "In Surrey, and round the metropolis, grounds intended to be mown are scrupulously freed from stock early in the spring; not a spring shoot is cropped. This is the opposite extreme; and, if the land will bear stock, is also improper. Some valuable spring-seed is lost; the frosts destroying that which would be of service to stock.

"Land may in general be eaten until old Lady-day or the middle of April, without injuring the crop of hay. Early weeds, and the ranker grasses, are choked, by which means the better bottom grasses are suffered to rise, and to ripen with them.

"To give a minute account of the department of the grass-land management, it will be requisite to consider separately the following divisions:

1. Mowing:
2. Making:
3. Laying up.

"1. Mowing. This is done chiefly by the "*day's mowing*," which is an inaccurate acre; sometimes more, but generally less than a statute acre; old inclosed meadows having been reckoned from time immemorial, so many "*day mowings*;" and whether they are in reality a greater or less number of acres, they are considered as so many days' works.

"The wages for mowing, one shilling to eighteen-pence a day and board. Little or no mowing is done by the acre. A man seldom mows more than his day-mowing: which, if he be a good hand, he performs in a few hours, in the morning and evening; generally lying by in the middle of the day.

"The Yorkshire mowers labour hard during the short hours they work: their *sithes* are of uncommon length, and they take their *swath* of unusual width; seldom less than three yards; some of them ten or eleven feet wide; and, what is I believe peculiar to them, they invariably "*keep stroke*;" that is, all strike together as one man: a practice which is at least pleasing to look at.

"2. Making. All countries, I find, abound in bad hay-makers; and some are destitute of good ones. The country under survey may be said to be above par; and that is as much as can be said of it. Quantities of hay are annually wasted, and still greater quantities unnecessarily injured, through bad management. It is seldom tedded sufficiently; is frequently exposed all night abroad in catching weather; and in such weather is too often carried before it be dry.

A singular expedient is here practised to get it (as it is intended) out of harm's way. This is to put it into "*pikes*," or *stacklets* of about a load each, before it be fit to be put into *stack*; and, too frequently, before it be fit to be put into large *cocks*. This is considered as a middle stage; in which it is to take a partial heat, and become prepared for the *stack*.

If hay be free from water-wet, but yet too full of sap to be trusted in *stack*, "*piking*" it may have its use. But it is more generally made use of as a slovenly expedient for getting hay out of hand in a tedious season. In this case, however, it is mostly mischievous. I have seen these *pikes*, when opened out to be carried to the *stack*, white with mould, black with rottenness, and of every intermediate colour, excepting that which alone is desirable. But this good old way seems to be declining.

In the best practice of the district, the grass, in fine weather, is tedded after the mowers; or, in showery weather, as soon as a fair opportunity offers. In the evening, unless due confidence can be placed in the weather, it is put up into *cocklets*, provincially "*hipples*;" made in different ways; some being set up hollow with the foot and the head of the rake; others in the common way with forks. As the hay has advanced in dryness, the *hipples* are increased in size.

"When a fair opportunity offers, and the grass is perfectly dry, the *hipples* are "*fundered*;" that is, broken out into beds in the usual manner; turned; and again got up into *cocklets*, of such size as the state of dryness requires. When sufficiently dry, the hay is made into well-sized *cocks*; namely, about eight or ten to the load.

When the crop is intended to be stacked on the piece it grew on, the first-made part generally stands in these *cocks* until the whole, or the principal part of the remainder, be ready for the *stack*; which, by this means, is never exposed abroad in its first stages: a circumstance, however, which is too commonly suffered by less judicious hay-farmers.

"3. Laying up hay. The most prevalent practice is to *stack* it in the field, either for the purpose of foddering it on the ground, or to be fetched home in frosty weather, or when wanted. Much, however, is carried to the home-stall at hay-time; some to be stacked; others to be housed; a practice which, when room can conveniently be had, seems to be in good estimation. It is at once got out of the way of the weather, and probably into the place in which it will be wanted: the mustiness of housed hay, which is talked of in some places, is not perceived in this.

"The practice of stacking hay in the field adds much to the ease and dispatch of hay-time. If the *stack* be placed in the center of the ground, a considerable part of the hay may be collected, without the trouble of loading it on to a carriage.

"If it be in large *cocks*, it is sometimes drawn to the *stack* with one horse, and a cart-rope put under the skirts of the *cock* on the sides, and above the skirts on the back part; giving the bend of the rope sufficient hold of the hay, to prevent its being drawn from under the *cock*. The two ends of the rope pass to a pair of hames; being made fast on one side, and kept in its place with a peg on the other; the *cock* arrived at the *stack*, and the peg drawn, the rope is disengaged.

"If the hay be abroad it is rowed in the usual way, and is sometimes drawn together with a long pole (six or eight feet long), with a rope passing from each end of it to the hames; a man standing or pressing upon the pole, to keep it down to its work, and make it clear the ground as it goes. This however, though simple, is a difficult business.

More complex implements of various constructions have therefore been contrived for this purpose.

"These implements are also used in cocking; and, when the quantity of dry hay is great, and hands scarce, it eases and expedites the business very considerably. For, in this case, the main burden of the hay is drawn together by the team, the rakers having only the bared ground to rake over; following the implement, and drawing the rakings to the part to be cleared by the next sweep of the implement; beginning on one side of the piece, and proceeding in this regular and expeditious manner to the other; leaving the hay in large rows, easily to be cocked; dragged to the stack; or loaded; as occasion may require. This expedient, however, is far from being in general practice.

"When the ground near the stack is cleared, and the stack has risen too high to be conveniently forked on to from the ground, the outskirts of the field are drawn together in carriages.

"In the best practice of the district, the stack, if not very large (which field-stacks seldom are), is never begun upon until a sufficiency of hay be dry to get it above the eaves the first day. If the whole be ready, the middle of the stack is rounded up, and the remainder set in tall "pikes" by the side of it, ready to be laid on the first fine day after the stem be sufficiently settled. This appears to me to be bringing the business of laying up hay as near perfection as the nature of it will admit.

"Field-stacks are, I believe, invariably, made round. The favourite form at present seems to be that of an egg; a form, perhaps, of all others the most beautiful, but by no means the most convenient.

"When the hay has done heating, the stack is finally topt up, its roof adjusted and raked, and its top cap with thatch; the principal part of the roof being left naked."

"In a country where thatching the entire roof is the established custom, this would appear negligent management. In this country, to bestow thatch and thatching upon the whole would be deemed a wasteful extravagant custom. It would be difficult to say with certainty which is the better practice. Either of them is good, if properly executed.

"Field stacks are fenced with large hurdles, provincially, "stack-bars," resembling the gate-hurdles of some districts, and the cattle-hurdles of others. Being placed in a ring, and united together with pins passing through the heads, they form an arch, and become a simple and sufficient fence against every kind of stock."

Mr. Marshall, in his Minutes of Agriculture, says "he adapted the following method of making mix-grass and clover-hay: let it lie awhile to wither in swath; but while it is tough, before it be crisp, make it into light minikin cocks, and rake the bared surface. As the cocklits become dry, aggregate them; and continue to rake the bared grass till the hay be dry enough, and the cocks big enough. If rain beat down the cocklits, catch a dry opportunity of turning them upside down and lightening them up, not shaking them up. Thus it will be always out of harms way, and the leaf, sap, and colour be preserved. Never ted a light or a middling crop of grass of whatever species. If the weather be fine let it make itself in swath: if foul, make it in cocklits. Hay makes faster in heaps of whatever shape or size, than is generally imagined, especially in windy weather. It is amazing how much large heaps dried, after they were mixed and shook light up.

"He also observes that carters are as wasting servants as any in a farm, for while they have their hay given to them for their cattle bound, they will keep up to a truss a horse a week; but if not, they pay no attention to what quantity may be consumed. This waste of the carters must fall, more or less, to every farmer who does not attend to the minutiae of farming. He recommends every blade to be bound, even that which is to be consumed at home, notwithstanding the expence of twenty pence per load; by which he was enabled to keep an account at hay-time, of the field-loads which were put into each stack, and by that know what was yielded in each field, and how much each stack contained. Besides this he was enabled to prevent waste; as no litter was made of it in the stack-yard, &c. but every mouthful delivered to the respective feeders. This alone will repay the expence; and he could allowance each species of stock, viz. each cart-horse a truss a week; the ox-team half a load a week; the milch cows, one, two, or three trusses a week if they are wanted, &c. &c. He found by this method the men became more careful, and imper-

ceptibly learned frugality, and did not give the cattle too much by half at once, and throw what they had left, and blown upon, under them for litter. This method Mr. Marshall says enabled him to have the satisfaction of knowing how every blade was expended; how much each sort of hay-eating stock cost, during the winter; and of course the hay and stock accounts were reduced to a certainty."

For the method of making lucerne and saintfoin, see the articles LUCERNE and SAINTFOIN.

HAY-BOTE, a liberty which a tenant for life, or a term of years, has of taking bushes, wood, &c. for repairing fences, gates, and the like. It also signifies the liberty of cutting wood, for making rakes and forks used in making hay.

HAYN, or Hayn-up, implies the action of inclosing with a hedge, in order to preserve grass-grounds from cattle.

HAYWARD, or HAWARD, a keeper of the common herd of cattle of the town, who is to look that they neither break nor crop the hedges of enclosed grounds, and is sworn in the lord's court for the performance of his office.

HAZLE-Mould, a moderately compact earth, containing a large quantity of resin-coloured sand.

HEAD-LAND, the land running across the others at the head of the field, left for the turning of the plough.

HEAD of a horse should be narrow, lean, and dry, neither should it be too long: but the main point is a good onset, so as he may be able to bring it into its natural situation: which is, that all the fore parts, from the brow to the nose, be perpendicular to the ground, so that if a plummet were applied thereto, it must just raze or shave it.

Every horse that has a large head, is apt to rest and loll upon the bridle, and by that means, in a journey, tire the hand of the rider; and besides, he can never appear well with a large head, unless he has also a long and well turned neck.

HECK, a door; also a rack for cattle to feed at.

HECKLE, an instrument used in the dressing of flax and hemp. See the articles FLAX and HEMP.

HEDGE. See FENCE.

HEE-GRASS, stubble of grass.

HEIRS, young trees in coppices.

HELL-WEED. See BIND-WEED.

HELM, a hovel; also straw prepared for thatching.

HEMP, the name of a plant too well known to need any description here; but it may not be improper to remark, that the flowers and the fruit (commonly called seeds) of hemp always grew separately on different stems, and consequently on different plants, as this never has more than one stem proceeding from the root.

The flower-bearing species, which is the *Cannabis florifera*, Off. *Cannabis erratica*, C. B. P. *Cannabis femina*, J. B. *Cannabis sterilis*, Dod. Prempt. and which is most frequently termed female hemp, should properly be called barren hemp, flowering hemp, or male hemp, since it is this which bears the *farina fecundans*, or fecundating dust, without being impregnated with which the seeds that grow on the other stems of the other species would not come to maturity, or at least would not be capable of producing plants, when sown.

This other species, which bears the seeds, and which botanists distinguish by the appellation of *Cannabis fructifera*, Off. *Cannabis sativa*, C. B. P. *Cannabis mas*, J. B. *Cannabis fecunda*, Dod. Prempt. and which is commonly termed male hemp, should be called seed-bearing hemp, or female hemp; because it is this which, with the help of the impregnation it receives from the *farina fecundans* of the male, produces seed capable of yielding plants of either species.

What may chance to be the future proportion between the number of male plants, and that of female, in a hemp-ground, cannot possibly be guessed at the time of sowing, as no sort of mark can be discerned on the seed, by which they may be distinguished: nor indeed can any judgment be formed in this respect, before the male plants begin to flower, that is to say, in general, till about two months after sowing: unless it be from a remark which the most curious observers have made, that the male hemp is slenderer than the female, and that all its parts are more delicate: to which may be added, that the male plant is always forwardest in its growth, and that it generally rises about half a foot higher than the female; thereby plainly indicating it to be the design

design of nature, that the fecundating dust which issues from the flower may by that means be the more easily conveyed to the grain on the seed-bearing stalks, in order to its impregnating that seed.

With regard to the temperature of the air that is fittest for the growth of hemp, M. du Hamel observes, in his *Treatise on Cordage*, that this plant does not like hot countries; that temperate climates suit it best; and that it thrives pretty well in cold regions, such as Livonia and Canada, which produce it in abundance, and very good. M. Marcandier is indeed of opinion, that though extremely hot countries are not favourable to its growth, yet, as this plant is but a short time in the ground, it may be cultivated in any place that is habitable by men.

Mr. Young, in his *Annals of Agriculture*, inserts the following extract, translated from the Italian, on the subject of the culture of hemp in the Lower Montserrat.

"Among the many productions of the Lower Montserrat, hemp is the most advantageous; for it is without doubt that what is raised in this province, and especially in the territories of Mancalvo, Tonco, Alfiano, Villadeati, Murisengo, Montiglio, Scandaluzza, Rinco, and Colcavagno, exceeds in fineness, length, whiteness, and strength all others: since the merchants who are in this trade, and particularly the Genoese at the fair of Alexandria, prefer it to all others, collecting it in great abundance, besides the quantity which every proprietor retains for his own use.

"The influence of the air, and the constitution of the soil, are the circumstances that first contribute to good success, and to the greater perfection of all products.

"I have, with great ease, observed, that the same seed sown in different scattered lands has prospered much, when cultivated with the necessary attention; and equally degenerated from its kind. The first produces hemp, the *lisca* of which (*lisca* are the small canes of the stalks, from which the water in maceration has separated the filaments of the bark) is thin and slender, and the thread white; but of the second the hemp gained has a gross thread; and the *lisca* approximates to wood. It will be proper to indicate in the cultivation the cause of this variety, and the method of amelioration.

"The first care of those that cultivate hemp ought to be, to chuse a soil adapted as much as possible to this sort of plant; for it is well enough observed by Virgil that *non omnis fert omnia tellus*. At present the soils that agree with it best, as well as I can comprehend from the observations I have made, are those situated at the foot of hills, or rather such as are situated in plain vallies, and exposed to the rising and setting sun. The reasons why hemp flourishes in such situations are many. For first, these lands, by their nature black, and alone receiving the rain, which washes the higher grounds, are more penetrated with moisture, which, more than any other thing, contributes to the increase of this plant.

"In the second place, it is to be observed that this running water is very fat and rich, from enveloping in its course whatever the winter-rains wash from the higher manured lands, depositing it in these vales: and this sediment serves not only as a manure to the hemp, but to revive and guard it from the more burning rays of the sun. To this if we add that the soil of vallies and the slopes of hills receive new deposits of earth and of dung, they remain by consequence less solid, by which the tender hemp may more deeply push its roots. In land more compact and hard I have practised, with good success, the mixing the *lisca* and the roots of the crop of the preceding year, which I have had stamped and broken minutely and macerated in dung, which has had the effect of rendering the earth lighter, more fragil, and less solid.

"After having made choice of the earth, the farmer must think of preparing it, in which the ordinary culture and the manure which is spread upon corn-fields, are not sufficient; for if the land is not deeply stirred, and well raised oftener, the crop will always be poor, inasmuch as its nature is to push into the ground. Many of our husbandmen annually manure their land with dung of a hotter nature, as well as more minute; as that of poultry, of sheep, and also of neat cattle and horses, but not fresh and four, but kept long in the maceration of a compost. In the month of November they dig the field with a spade, stirring the soil to the depth of a foot; with the aid of this labour, the nutritious juices of the earth, that have been much sunk beneath, are raised to the surface of the earth.

"In many of our lands I believe it is enough to break with

the plough and work it with the spade every fourth year, in the above-mentioned manner. An annual digging contributes greatly to the abundance of the crop, but the hemp is apt to be too gross and of a worse quality.

"The first ploughing should be given with a deep furrow, to move every part of the staple, in the month of September, or in the beginning of October; and the manure spread in the beginning of December, in order that it may be well incorporated with the earth in the spring. It happens in certain dry years that clods, more or less large, are raised by the plough, which being penetrated by the winter's rains, and by the snow, and broken by the action of frosts, the land more easily divides, and levels by the last furrow, and rests in consequence less subject to dry: the same action of the frost and cold influences to the more efficacious incorporation of the manure with the earth, fixing the volatile salts which are more abundant in such a situation. The last earth should be given in the full moon of March, the season for sowing hemp.

"In regard to the quantity of manure, the common rule is, that to every *stajo*, which is the 8th part of a *moggio* (corresponding more or less to 1-18 less than an acre), two loads are enough, of common ox-dung well rotted, called in the Montserrat *baroffe*; less should be used if the dung is heating, reduced, and resembling that of sheep and poultry: but the nature of the land and of the manure must determine the quantity.

"Respecting the time of sowing hemp, the only observation to be made is, that the full moon of March should be the direction; it appears that that period is more favourable to the sowing, as the seed is at that season less exposed to the ill effects of frost, and the too great heat of the sun, both equally hurtful to the unfolding of the seed, and the growth of the tender plants.

"The seed ought to be buried with the harrow commonly used: the seed should be of a good kind, and sown thickly and equally, and if when fresh done there comes a moderate rain, it will be better covered and spring more easily. This effect is such that our farmers, when they foresee rain, are solicitous to sow their hemp.

"A *stajo*, the eight part of a sack of Montserrat, is more or less, the quantity of seed necessary for sowing a *stajo* of land, which, as mentioned above, is the 8th of a *moggio*.

"Care must be taken that if the earth is not sufficiently broken by the harrow, to the degree of minuteness of a garden, and be not laid perfectly level and the seed well covered, in such case it should further be gone over with a wooden machine, like a rake, to break every little clod that is left.

"The sowing being finished in the manner above-mentioned, there are divers necessary precautions, which the cultivator ought to take for contributing to the more easy and prompt vegetation of the plants: attention should be given to break that crust which easily forms on the surface of land that is strong and fat, especially when a hot sun succeeds rain; the humidity thus penetrating, with the action of the sun and air, is an advantage in enabling the plant to develop itself with greater force, and expand its roots with more freedom; thus giving, with an increased porosity, increase of nourishment. It is also necessary to remove, throughout the season, every useless and noxious herb, because the roots of the hemp will be left more at liberty, and meet a more copious nourishment; and this object will guide us in rejecting a common practice of sowing other plants with the crop, as rape or lupines; arising from the ill-founded principle that the roots of these plants will prove a manure the following year. Another attention is also important, and even necessary, for preserving and defending the seed which has germinated; and this is, to hang rags of different colours at the angles of the field, which being agitated by the wind, will frighten away the birds.

"With respect to the time of gathering hemp, there is a vulgar distinction between the male and female.

"It would be difficult to correct the error of our peasants, habituated by custom to call the male plant the female, and *vice versa* the female the male, for which reason I deem it useless to dwell on the improper denomination of this plant of two sexes, the more so as the question would not be productive of a change in the method of cultivation. The latter ought to be first gathered, when the flower is dropt and the plant appears yellow at top and white towards the root, which is generally the case towards the latter end of July, or beginning of August, according the greater or less heat of the season, or the more or less advantageous situation and position of the land; then, therefore, the plants are rooted up,

up, tied in bundles, and the roots are cut off, afterwards they are left exposed to the sun.

"The common practice of leaving the hemp exposed to the heat of the sun, in such a degree as to occasion the leaves to fall off sooner, is by no means to be approved of, but beating it against a wall, or pulling off the remaining leaves by force, is infinitely more hurtful: but great care ought to be taken to preserve them from rain, which would cause the hemp to be spotted, which black spots appear after watering.

"The method of keeping the bundles of hemp under cover, and no ways exposed to the heat of the sun, appears to be preferable; the reason is natural, the hemp exposed to the sun dries too much, by reason of the glutinous matter which surrounds it; the threads, occasioned by the mellowness produced by watering, are separated with less difficulty; they are from thence, conveyed to a pond, or pool, before they are too much dried. The pools, or ponds, being situated in the vallies, receive the running waters from the warm, and rich hills, which, from experiment, have been found more beneficial to the hemp than cold and raw streams. These pools are pits of certain dimensions and depth, are contiguous one to the other, in such a manner as to flow from certain apertures, and the super-abundant waters are communicated from one to the other; the owners of these have them cleared yearly, and require for each watering a small reward of hemp in kind.

"The peasants, who have the sole direction of this work, take particular care to put the hemp in water into the same pits; each pit commonly containing four heaps divided amongst them, vulgarly called *gombine*, composed of forty *fusare*, and each of these of ten bundles.

"The degree of time and the duration of the watering cannot be with certainty ascertained, since that must depend on the hemp being more or less thick, the situation of the pits and the degree of heat of the season: in general six or seven days are sufficient, and the goodness of it is known when the heaps begin to swell, and they raise the weight to the surface of the water in which it is contained; the same peasants, to ascertain the degree with greater accuracy, observe whether the hemp has taken a yellow colour, and whether the threads separate with ease from the liska, examining at the same time the surface, center, and bottom of the pit.

"Afterwards the male plant is not rooted up, but it is cut down when the seed is ripe, leaving the root in the ground: the ripeness is known by the stem becoming yellow, and the seed grey, which happens towards the latter end of August; or beginning of September. It ought to be cut close to the ground, because the shaking which rooting them up occasions, would be attended with loss of the riper seed; and when gathered together, and divided into bundles, it is placed in the watering pits, where it ought to remain twice as long as the female plant.

"It has above been observed, that it is not easy to ascertain the degrees, or length of time it ought to remain in the pit, since that must chiefly depend on the greater or less efficacy of the water, which, by means of fermentation, penetrates the rind of each plant of hemp, separating it from the cane, and loosening the threads one from the other, for which reason the greater or less perfection in the watering of either the male or female plant can only be known by the more or less difficult separation of the threads.

"When the watering is completed, the same peasants take the heaps of hemp from the pit, which being well washed, they distribute and spread them one by one in the shape of a coop, in order that the water may run from them with greater ease; in this manner they leave the heaps to dry by the sun, and from hence put them under cover, because hemp ought to be kept dry, that when it is placed under the *spaulatura* the cane may easily separate from the threads.

"Every operation attending the culture of hemp will be useless, if the utmost care is not taken in collecting the seed, on the goodness of which the success of each of the species materially depends.

"The seed, therefore, is gathered from the plant vulgarly called male, which, being shook and beat, is left to dry in the sun, removing it from time to time to prevent fermentation; and as too much heat, as well as dampness, is equally hurtful to the preservation of the seed, it is highly proper to keep it under cover and defended from the air.

"With respect to the method of insuring the quality, and perpetuating the species of the best seed, these ought to be gathered from the plants produced from the male, and cul-

tivated in the same field, in which the female has been produced, as experience proves that any other seed soon degenerates.

"During the time of cleansing or sifting, the larger seed should be picked from the smaller, and they alone ought to be preserved for the next sowing."

The wise legislature of this country has shewn its opinion of the importance of raising hemp in our own dominions, by the bounty given by parliament for the importation of it from North America; and our truly laudable Society for the Encouragement of Arts, Manufactures, and Commerce, likewise judiciously contributed to this desirable end, by offering a very considerable premium to the cultivators of hemp in those late provinces of the British empire.

The soil for hemp should be a soft rich loam, easily brought into fine tilth; and it should be well manured. Newly broken up land is found to be peculiarly good for this plant; but flat grounds lying on the sides of rivers, and enriched by the sediment left on them when the waters overflow, are the best of all for it. If hemp is to be sown on very strong soils, they must be brought into so good tilth, and be so well manured, that their mould may remain loose: in this case, such soils yield very great crops. Dry lands are not fit for hemp: it does not rise well in them, but remain short and stunted in its growth, and its fibres are then generally too woody, which renders them hard. All these are considerable defects, even for the coarsest works. It is however true, that, in rainy years, it succeeds better on dry grounds than on moist: but as such years are not the most common, the best situation for hemp-ground is generally thought to be along side of a stream, or of a ditch so full of water, as that the water may constantly be nearly on a level with the surface, but without overflowing it while the hemp remains on the ground.

It is the custom in some countries to form hemp-grounds, which are appropriated solely to this purpose: whereupon the author of a very judicious account of the culture of hemp, in the Memoirs of the Royal Society, of Agriculture at Tours, justly observes, that, "besides that all soils delight in a change of plants, hemp is so far from impoverishing the ground, that the leaves which fall from it become a sufficient manure, and the depth to which the roots go, especially if the crop of hemp be great, leave the ground sufficiently loose to sow upon it even a crop of wheat immediately after the hemp has been pulled, without any other expence than sowing the seed and harrowing it in; or if turnips or a spring crop be more convenient to the farmer, these also will thrive well after the hemp. It is said, that the hemp which grows on an established hemp-ground is softer and more silky than that which is raised elsewhere: but the difference, if any, is very inconsiderable; for the hemp which grows in the other parts of Anjou, for example, is found to be as good as that which is produced by any of the few established hemp-grounds in that province."

As it is essential to have the ground in exceeding fine tilth, the first ploughing should be given it as early in the autumn as the husbandman's other business will permit. Some are so curious in the preparation of their ground for hemp, that they give this first stirring by hand: and though it be a more tedious and more expensive way than ploughing, they think that the difference of the crop repays them well. In whatever manner it be done, the ground should be loosened as deep as possible, and laid rough, that it may be the better mellowed by the winter's frost, especially if the soil be strong. If the hemp is to be sown on ground purposely broken up, and which is covered with coarse grass, or other similar productions, its surface should be pared off and burnt; or it should otherwise be brought to a perfectly fine tilth. The ground should be ploughed again in February, or more early if the season will permit; and then also should be laid on the manure, whether of horse dung, or the scouring of ponds and ditches, after it has had time to ripen; for these are preferable to cow-dung; though all manures, which render the earth light, are fit for hemp. Mr. du Hamel remarks, that marle is not, to his knowledge, used for this purpose. He likewise thinks, that it is best to dung the hemp-ground every year before the winter ploughing, in order that the dung may have time to rot during that season, and that the spring ploughing may afterwards mix it the more thoroughly with the earth: for all hemp grounds should be well dunged at least once a year.

To prepare the hemp ground thoroughly for receiving the

the seed, it should have two or three good ploughings in the spring, or even more if the farmer's convenience will permit, and the nature of the soil be such as to admit of them; for the more frequently it is stirred in the spring, in proportion to the quality of the soil, the better the crop will be. About a fortnight or three weeks should intervene between each of these ploughings, and they should at last lay the ground quite smooth and even. If any lumps or clods of earth yet remain after all these ploughings, they should be broken by hand; for the whole hemp-ground must be as level, and of as fine a mould as the beds of a garden.

The first spring ploughing should be given across the former: and before the next ploughing is the proper time to spread sheeps dung, pigeons dung, poultry dung, or whatever other such like manures are used; though still it is to be feared, that, if the spring prove dry, these hot dungs may burn the seed, which they would not do if they were laid on before the winter: but in this case a greater quantity of dung must be used, or less advantage must be expected from it.

The necessity of manuring land every year for hemp, and at the same time the uncertainty of the succeeding season, whether it shall be hot and dry, or cold and moist, render the culture of hemp a matter of much difficulty to the farmer, what quantity of manure to lay upon the land, and of what quality; especially if manured with dung. There are two methods of avoiding this difficulty in some measure; one is, to give a light dressing at first, and as the season advances, to give the land repeated hand-dressings with powdered manure, to be from time to time sown over the crop, and repeated according to circumstances of weather, and appearance of the crop. This may be done at a small expence, and is ready at all times; such fine manure is readily washed into the ground by the first shower of rain, and the effects of it are quickly visible, which will direct the farmer what kinds of manure are most proper, and when to repeat the dressings. A mixture of different kinds of manure, is in general most proper for this use, or sometimes of one or two sorts only, suited to the nature of the land: but of whatever kind the manure is, it should be previously dried, and pounded fine. Such dressings are excellent for many kinds of plants; which they cherish and bring forward gradually, much more agreeably to the course of nature, than it is to lay on a large quantity of manure at once, the good or bad effects whereof depending upon the season, must ever be very precarious.

When hemp is cultivated principally for the seed, it is much the best way, as observed in the culture of flax, to sow it thin, to give it room to spread and throw out many branches, which will produce much seed; and if the plants are raised on beds or ridges, in rows, and horse-hoed, the seed will be much superior to what is obtained from broadcast hemp.

This plant may be also cultivated to great advantage, in respect of both seed and hemp, by drilling it in equidistant rows, and hand-hoeing; which will improve the land and crop, with less manure, than sowing it by hand.

The season for sowing hemp depends in a great measure on the quality of the soil. In dry light ground, it should be sown as soon as the danger of frost, or other inclemency of the weather, is over, in the latter end of April or beginning of May, that so it may get up early, and, by covering the ground, prevent the danger of drought. In wet cold grounds, it should be sown later, that is to say, not till the sun has exhale the too great moisture of those grounds; and this may not be till the middle, or even the latter end of May. The author of the before-mentioned account of hemp, in the Memoirs of the Royal Society of Agriculture at Tours, advises to sow hemp even so late as the latter end of June, in case the season for it be not favourable sooner; and he observes, that the crop sown then will be as plentiful, and of as good a quality, as if the sowing had not been delayed so long, especially if a very dry season does not come on immediately after. The truth of this is evinced by the experience of those who are obliged to sow a second, and sometimes a third crop, when their former sowing has miscarried through the inclemency of the weather, and particularly of frost, which is a great enemy to hemp. Another reason too, which he assigns in favour of late sowing of hemp, is, that the husbandman may by this means have an opportunity of destroying the first growth of weeds, which would choke the hemp, if it were sown before they had come up.

The hemp-seed that is sown should always be of the growth of the preceding year, because, as it is a very oily grain, its oil is apt to become rancid, if it be kept long, and the seed then loses greatly of its vegetative power, in so much, that, when it is two years old, many of the grains will not rise at all; and if it be older, a yet less quantity will grow. Experience has also proved, that, as in other grain, so likewise in this, it is advisable every second or third year to choose the seed from a soil different from that on which it is to be sown.

The husbandman should be particularly attentive to the weather, when he sows hemp, for the season then should neither be too dry, nor too rainy. If either of these is the case, he had better defer his sowing: though he should, if possible, always choose a time just after a gentle fall of rain.

When the soil is deep, and in fine order, it is best to sow this seed thick, especially if the hemp be intended for fine uses, because the plants run most into height, when they stand closest together, and their fibres are then by much the finer. They should not, however, stand so very thick as to choke one another; because this would occasion a considerable loss of plants. It is therefore necessary to observe a medium, the knowledge of which is easily acquired by practice: and indeed, in general, hemp-grounds seldom are too thinly stocked with plants, unless when part of the seed has been destroyed by frosts, drought, or other accidents. The usual quantity is three bushels to an acre.

As soon as the hemp-seed is sown, it must be carefully covered with earth, either by means of a harrow, if the ground has been ploughed, or with a rake, if it has been dug by hand; and besides this precaution, the whole hemp-ground must be constantly watered till the seed has risen; for otherwise numbers of birds, and especially pigeons, will destroy it entirely, without sparing even the seeds that have been well buried. It is true, that pigeons and birds which do not scratch, do no great hurt to the grains of corn that are well covered with earth; but the husks of these grains do not rise up out of the ground with their green shoots, as those of hemp always do; and then it is that these birds, mistaking them for perfect seeds, tear them away with the young plants to which they adhere, and thereby commit vast havoc. So greedy are the pigeons, in particular, after these seeds, that none of the common ways of frightening birds will keep them off: nay, M. du Hamel assures us, that he has seen strong men, and even dogs, so wearied out with fatigue, as to be forced to give up the task, when the hemp-ground has been large. Happily this troublesome work does not last long; for when the hemp has put forth a few leaves, it requires no farther tending.

Though hemp cannot be weeded without great hazard of damaging the crop, because whatever plants of it are twisted, bent down, or broken, through inadvertence of the weeders, or by any other cause, never rise again; yet if the weeds are so numerous and rank, as to endanger their smothering of the hemp, it is necessary to root them out, and the most careful persons must be employed for this work, which, when rightly executed, is also attended with this farther advantage, that the pulling up of the weed loosens the surface of the earth, and thereby forwards the growth of the plant.

In very dry seasons, it will be proper to overflow the hemp-ground, if it can be done. To this end some authors advise letting in the water from the ditches, as is practised from rice-grounds. If any parts of the hemp ground are in danger of being burnt up, it will be advisable to water them, or perhaps rather the whole in such case, even by hand.

If, by any accident, the hemp grows very thin, so as to be thereby in danger of branching out too much, and of becoming woody; this should be an additional motive for keeping it perfectly clear of weeds, in order to let it remain for seed, which will be so much the better for the plants having stood thin.

The male hemp (which is the species that produces the *farina facundans*) ripens earlier than the female, generally by three weeks, or even a month: but the time of the ripening of either depends much on the nature of the soil. The male hemp shews its ripeness by turning yellow at top, and whitish at the bottom of the stem; but this sort, in particular, should be pulled rather before it is quite ripe, that is to say, while it is yet somewhat green; for if it be too ripe, its fibres will adhere so strongly to the seed, as not to be separated therefrom, without some loss; neither

will they be so soft, and consequently not fit for domestic uses, as those of hemp that is pulled before it has attained to a perfect maturity.

The ripeness of the female or seed-bearing hemp, is known, not only by the same signs as that of the male, but also by the seeds beginning to turn brown, and by the capsules, which contain them, beginning to open.

As soon as the male hemp is ripe, it is pulled stem by stem, and with caution, not to injure the female hemp, which, as we before observed, must remain on the ground some weeks longer, that is to say, till it also is ripe, and then it must likewise be pulled stem by stem.

Each handful that is thus pulled should consist of plants, as nearly as possible, and placed as even as can be. Some tie up each handful, especially of the male hemp, with a stalk of hemp, then lay it in the sun to dry its leaves and flowers, which they afterwards beat off, by striking it against a tree or wall; they then put several of these handfuls together, so as to form a pretty large bundle, and in this condition they carry it to the watering place.

We have just mentioned what M. du Hamel says of the common practice of drying the hemp before it is steeped: but we must here observe, that it is a matter of doubt, whether this plant should be dried before it is steeped. Those who are for drying it first, say, that the hemp becomes thereby stronger than when it is steeped without having been previously dried: for my part, I must confess, that this drying seems to me to be a needless trouble; for as it is necessary in the steeping of hemp, that a certain degree of putrefaction should arise, sufficient to destroy the texture of that glutinous substance which connects the fibres to the woody part of the hemp, it certainly is more advisable to lay the hemp in the water as soon as can be after it has been pulled, because the more there is of the natural moisture left in this glutinous substance, the sooner the putrefaction will begin. If, either by design or accident, the hemp has been dried, the putrefaction comes on more slowly and more unequally, and the fibres contract a hardness which the steeping afterwards will not easily correct.

The common height of hemp, when full grown, is from five to six feet: but M. du Hamel remarks, that the stems of the hemp which is cultivated near Bischwiller, in Alsace, are sometimes upwards of three inches in diameter at their bottom, and above twelve feet high. These, indeed, are so deeply rooted, that even a very strong man can hardly pull them up.

When the female hemp is let stand till its seed is perfectly ripe, its bark becomes woody, and so coarse, that no future operation can bring it to a proper degree of fineness. For this reason, it is generally pulled before the seed is quite ripe: but as it is manifestly the husbandman's interest to sow none but the best seed, he ought not to grudge the sacrificing of the goodness of a small part of his hemp, to the superior advantage of obtaining perfect seed by letting a proper number of these plants stand till their seeds have attained full maturity. The judicious M. de Chateaufieux, whose attention extended to the most proper method of cultivating every useful plant, did not neglect so important an object as the quality of the hemp employed in cordage, and the means of obtaining its seed in the greatest perfection. However, not having had opportunities of continuing his experiments long enough to draw certain conclusions from them, he invites all those who have the public good at heart, to make experiments which may lead to the utmost improvement of the culture of this plant: "but (says this friend of mankind,) these motives of economy are vastly inferior to the inestimable advantage of saving ships, their cargoes, and their crews, which often depends on the strength of the sails and cables."

On the twenty-sixth of April, 1753, he sowed six beds with his drill plough, placing six rows in each bed. The beds were seven feet wide, and the soil strong, but in very fine tilth. He treated his plants with great care, according to the principles of the New Husbandry: but both that and the ensuing year were unfavourable to the growth of hemp. However, he observes, in general, that his plants were five or six feet high, that their stems were large, and their bark very thick and strong. They were very fruitful in seed, especially the two outer rows, which had profited most by the hoeings. M. Aimen, from forty plants of hemp raised in the common way, and which might be deemed fine ones, had only a pound and an half of seed; but a single plant which grew by itself, yielded

him seven pounds and a half, of much better seed than any that is produced in the common way. From hence it results, that it must be of great advantage to the husbandman to set apart a spot of ground sufficient to rear thereon as many plants of hemp, as will afford him seed enough for the purpose of sowing, and to cultivate them according to the principles of the New Husbandry.

In some countries, to complete the ripening of the seed, round holes are dug, about a foot deep, and three or four feet in diameter, in different parts of the hemp-ground; and the handfuls of pulled hemp are set as close together as can be in these holes, with their seed ends downward, and their roots uppermost; after which, to keep them in this position, the whole is tied round with bands of straw, and the earth that was taken out of the hole is thrown up all round this great sheaf, so as quite to bury the heads of the hemp, which, when thus covered, heat by means of the moisture contained in them, in the same manner as a stack of green hay, or a heap of dung. This heat completes the ripening of the hempseed, and disposes it the more easily to quit its husks; and when it has been brought to this condition, the hemp is taken out of these holes, where it would become mouldy, if it were left longer in them. But, as is justly observed in the excellent Memoirs of the Royal Society of Agriculture at Tours, it is hard to conceive, how an operation which tends to bring on at least some degree of putrefaction, can ripen the seed; and therefore this must be at best a very dangerous practice, especially as a seed so very oily as that of hemp, and consequently so apt to become rancid, cannot but be liable to be rendered still more so by this degree of heat.

In other places, where the crops of hemp are great, the husbandmen do not bury the heads of their seed-hemp in the manner above described, but only lay it in heaps, with the seed ends one against another: others, whose crops are smaller, content themselves with spreading upon the ground a cloth to receive their hempseed; and others again only spread their bundles upon a clean spot of ground, with all the heads turned the same way. The seed ends thus placed are beaten slightly, either with a stick, or a light flail. The seed which falls out easiest is always the ripest and best, and should therefore be reserved for sowing the next spring: and as to that which remains in the heads of the hemp after this operation, it is got out by combing the heads on the teeth of a ripple, which pulls off the leaves, the husks of the seeds, and the seeds themselves, all together. These are gathered in a heap, and left in that condition for a few days, in order that they may heat a little, after which they are spread out to dry, then they are threshed, and finally, the seeds are separated by winnowing and sifting. This second seed is much inferior to the first, and accordingly it is used only for extracting oil from it, or feeding of poultry.

It is, on this occasion, justly remarked in the Memoirs of the Royal Society of Agriculture at Tours, that by the threshing of hemp there is always danger of bruising some of its seeds, and that the bruised seed will not grow, though it may be fit for yielding oil. Nor is this all; for, by threshing out the seed, there is a mixture of imperfect seed with that which is fit for sowing: and this is the reason why husbandmen have always found it necessary to sow a greater quantity than would otherwise be requisite, in order to make up for the uncertainty of its growth.

The method of separating the finest grains of wheat for sowing, by throwing the corn to a distance on a barn floor, is equally advisable for obtaining the heaviest and best hemp seed, where proper care has not been previously taken to provide such. In this case, the ripple may be used to separate the whole of the seed from the plant, and this will prevent the inconveniencies which arise from the threshing or beating out of the seed.

The method of laying the hemp down in order to its being steeped, is to place it in bundles at the bottom of the water, there to cover it with a little straw to keep the dirt from sticking to it, and then to load it with pieces of wood and large stones, to keep it down, so that it may be always five or six inches below the surface of the water.

The intention of steeping the hemp in water is, to make its bark part the more easily from the reed, and to destroy the outer skin; or, if I may here be allowed the language of anatomists, the cellular membrane which connects the hemp with the reed. All this is effected by only a small degree of putrefaction, so that it is dangerous to let the hemp

hemp lie too long in the water, for it will then be over steeped, that is to say, the water will not only have acted upon the outer skin and the connecting fibres, but it will also have lessened the longitudinal cohesion of the fibres; in short, the hemp will be too much rotted, and in this case the strength of those fibres will be proportionably impaired. On the contrary, when the hemp has not lain long enough in water, its bark adheres to the reed,—its fibres are hard, and they cannot ever after be rendered sufficiently fine. There is therefore a medium to be observed; and this medium depends, not only on the length of time that the hemp is to remain in the water, but also,

1. On the quality of the water; it being sooner steeped sufficiently in standing water, than in a running stream; and sooner in stagnant putrid water, than in that which is clear.

2. On the temperature of the air; for it requires less time to be sufficiently steeped in hot weather, than in cold.

3. On the quality of the hemp: that which has been raised on a rich mould where it has not wanted for water, and which has been pulled whilst yet a little green, being sooner steeped to a proper degree, than that which has grown on a stiff or dry ground, and which has been let stand till it was quite ripe.

In general, when the hemp has been steeped but a short time, its fibres are thought to be the better. Hence arises the opinion, that hemp should not be steeped but in hot weather; and for this reason also it is that many, when the autumn is cold, defer the steeping of their female hemp till the next spring. It is likewise for the same cause that some prefer steeping their hemp in standing water, or even in stagnant waters, that is putrid, rather than in spring or running waters.

M. du Hamel, to whom we are indebted for the foregoing remarks, steeped hemp in different sorts of water, and it appeared to him, that the fibres of the hemp steeped in putrid standing water were softer than those of that which had been steeped in running water: but they contract in water which does not run, a disagreeable colour, which does not indeed do any real injury to the hemp, for that which has been thus steeped is afterwards the most easily bleached; but yet, as this colour displeases, and the hemp is the less saleable for it, endeavours are always used, if possible, to make a small stream of water pass through the steeping places, thereby to change the water in those places, and to prevent its becoming putrid.

He succeeded likewise in rendering hemp fit to separate from the reed, by spreading it upon a meadow in the same manner as is practised for bleaching of linen: but he found this method tedious and troublesome; nor did the fibres of the hemp so prepared seem to him to differ much from those of hemp steeped in the common way.

He also tried the boiling of hemp in water, in hopes of bringing it speedily to the same condition as it is in when taken from the usual place of steeping: but when, after having been boiled upwards of ten hours, it was taken out of the water, in order to be dried, it was not at all fit for either peeling or breaking. It is true that, while it yet remained hot and wet, its bark separated easily from the reed; but at the same time it peeled off like a ribbon; the glutinous substance which connects the longitudinal fibres, and makes them adhere closely to each other, not being at all destroyed, so that they could not be separated, nor was it possible to divide them into fine threads. It is evident from what has now been said, that no precise time can be fixed for the steeping of hemp; since the quality of the hemp, that of the water, and the temperature of the air, hasten or retard this operation.

Mr. Young, in his *Annals of Agriculture*, vol. XIV. inserts the following method of cultivating and dressing hemp, by *Abbé Rulles*.

"It is sufficiently known, that land intended for a crop of hemp must be well manured, well ploughed, cleaned, and gotten fine; and the season being arrived, which varies much according to the soil, weather, and conveniency of the cultivator, extending from the 25th March to the 15th June; sow the hemp seed, which ought always to be new seed, thin, not exceeding two bushels to an acre, and if you have the advantage of a drill-plough, still less will do. After the land is sown, go through the whole with a shovel, and with it make little paths at seven feet distance from each other, the lengthway of your piece, so that at the proper season you may reach the female hemp, which you will have occasion to pull out, without trampling on the male, which must stand at least a month longer to ripen its seed.

The female hemp (which is that which bears only flowers and no seed) is known to be ripe by the flowers fading, the farina fecundans falling, and some of the stems turning yellow. You must then draw out carefully the whole of the female hemp, breaking as little as possible the stems of that which you take, or that which you leave.

"Immediately as it is gathered, take it in as large handfuls as you can, and either cutting the roots off, or leaving them on, as you like best (I prefer cutting them off) hold the root end uppermost, and with a wooden sword dress off the flower and leaves, which you leave on the field, since they assist in manuring; pick out any weeds or spoilt plants; put twelve handfuls or gripes together to make a bundle; then lay the bundles in water: it is much the best to be a running and clear water, and if shaded and overhung with trees the better: lay poles or planks, or whatever else you have that is suitable, across a large number together, so as to keep them at least two inches under water. Take particular notice which you lay in first, and how you lay the bundles, in order that you may be able to get them out again successively as they were laid in, without breaking or entangling. At the end of six days visit the hemp, and see whether the reed will draw out from some of the bundles. The time required for soaking depends very much on the nature of the hemp, the weather, and of the water it is soaked in—from six days to nine, or even eleven. It is a trouble that is not ill bestowed, to sort the hemp for soaking, if it is of unequal sizes, the slenderest generally requiring most soaking.

"When you find any quantity sufficiently soaked, take it out with care, putting the hands under it to prevent breakage, and transport it to a trough or to a table; for there are two methods of working it. If you work it in a trough, you must be provided with one somewhat longer than any hemp you mean to work in it—twelve or fourteen inches deep, and of what width you think proper, according to the number of persons you employ at it, as one, two, or four. To this trough must be fitted two pieces of plank, of about a foot length, but of such width as to stretch over a bundle of the hemp as it lies opened in the water: these planks must be set on one side with teeth of brass wire, and when the hemp is ready for drawing, must be laid on it as it lies in the water, to keep it straight and immersed.

"If you work the hemp on a table, you must, before taking it out of the water, open a little the bundles, and rub the stems between your hands to get off what you can of the slime, and to loosen the rind. You must likewise push the bundle along in the water, with the root end foremost, to loosen the rind at that end where the operation is to be begun. If you do not thus rub and scour your hemp in the water where you soak it, you must do it in the trough. But in either case you must be careful to keep an even and steady hand to avoid breaking the reed, which, as many times as it happens, renders the operation of getting the reeds out tedious. If it is wrought on a table, the bundle must be frequently but slightly wetted. If any suitable method could be taken to make water drip gently on it, it would be best. A plank must be laid on the bundle to keep it steady.

"All matters being properly disposed, either on the table or in the trough, you must begin at the root-end to push back a little the rind from the stem; then taking hold of one stem at a time, and rather nearer the outside than middle of the bundle, keep your hand and the reed under water (if you work in a trough) and draw it out from the bundle as straight as possible, you will find it come out clean as a sword from its scabbard. As you proceed you may take two, afterwards four, and up to six or more reeds at a time, which will draw out still more easily. When you have drawn out all the reeds that you can find at the root end, lift up the spiked plank which was at the upper end, leaving on that which was in the middle, and draw out such pieces of reed as you may find at the upper end, and which have remained after drawing out what you could at the root-end, because they were broken. Lastly, take off the plank which laid on the middle, and take out all the relics of reed you can perceive. If your hemp was in good condition for drawing, you will now find all your reeds perfectly clean on the floor, and the rind, which is the hemp, lying in strait threads, in the water or on the table.

"You will perceive that among the hemp there is a great quantity of gum left, looking like a jelly; this you will wash out as if you were washing any long straight piece of cloth, observing not to displace or twist the threads, which

which would thwart the future operation of dressing or heckling. The finer and whiter you desire the hemp to be, the more waters you will run it through, squeezing it out at each time of washing; but I think it always right at the last to run it through a water in which a slight quantity of soft soap has been beat up, after the rate of an ounce of soft soap to three pounds of the hemp when dry. Do not squeeze it out from this soap water, but hang it to drain, and when a little stiffened, open a little the bundle, and lay it to dry on a grass-plat or floor; the former is preferable. This soap-water is not absolutely necessary, but is certainly of great use for softening the hemp, and rendering it pleasant and easy to dress; but may be dispensed with where it is very inconvenient, and where the hemp is intended for coarse purposes. It is obvious that all these operations would be carried on to the most advantage near to some running stream or large lake, if it be a standing water, on account of the great use that is made of that element, and to save a great deal of the trouble of transportation.

"When thus dried, the hemp is proper either for dressing or storing: if the latter, particular care must be taken that it be thoroughly dry, it will otherwise heat and spoil. As the hemp peculiarly intended to be spoken of is the female, or flower-bearing hemp, which is intended for fine uses, it is to be observed, that it must be worked with heckles or hatchels, such as are used for flax-dressing, and may be brought to an extreme fineness; and the shorts, having no pieces of straw or reed among them, may be carded and spun, and brought into use for all the same purposes as cotton, and the same methods used for bleaching and softening. It is likewise requisite to work this hemp as soon as pulled, without which the greatest softness and whiteness cannot be obtained; and as this sort generally falls ripe between hay-time and harvest, when the weather is warm and fine, and the women most at liberty, it will be a suitable occasion to draw and cleanse the hemp; the dressing may be reserved for winter.

"I now proceed to speak of the male hemp, which being a more considerable crop, cannot all be worked as fast as it is pulled or cut. It is known to be ripe enough by the stems becoming pale; for if you stay till the tuft containing the seed appears ripe, or the stem turns brown, the hemp will be in a great measure spoiled. When it is come to a proper maturity, you must get a good number of hands, so as to expedite the business, because such as remains standing after it is ripe, will have its rind fixed to the reed, the gum turned hard and dark-coloured, and the whole operation of drawing becomes difficult, troublesome, and ungrateful. The leaves are to be stripped off with a wooden sword, in the same manner as those of the female hemp, as are likewise the seed, the branches which grow laterally and even the tuft-bearing seed at the top: but if this latter should not come off clean, it must be chopt off with an iron instrument. All this must be done over a cloth, or on a spot of ground in the field, well levelled and smoothed, to avoid losing any of the seed. And it is proposed, and said to be successful, to leave the seed abroad, covered with the leaves, &c. to preserve it from birds, in order that it may heat and be threshed in the field, and the leaves and chaff strewed on the land. This certainly saves trouble, and is practised in many parts, but seems to me slovenly, and I should rather take it home to a barn; but I would certainly burn all the roots, and such parts as are too hard to rot easily, and strew the allies as well as the leaves, and such other parts as will easily rot upon the ground, as, these matters are reckoned to go half way towards manuring the land for next year's crop. The male hemp, thus stripped of leaves and seed, will generally dry for storing in 24 hours; but at any rate must not be left long abroad, but rather taken into sheds to dry, which, when thus stripped, it will speedily do. Sun and rain would soon spoil it. That which can be wrought green must be treated as before set forth for the female hemp; and it is obvious that it is a great advantage to work it in this manner, rather than to dry and store it, which causes much trouble and expence, and produces less and worse hemp; but where the crop is considerable, and the hands few, it is unavoidable. If, however, much comes, it is impracticable to dry it for storing without spoiling, as every year's experience shews in the present received method: whereas the working the hemp green entirely avoids this disadvantage and inconveniency, and the hands engaged may continue their employment under the shelter of trees, or of a temporary shed made of a few rough poles and hurdles, covered with straw, reeds, &c.

"All the same procedure is to be used with the male as with the female hemp, as to drawing, scouring, &c. but as the reeds of it are less brittle, and the rind coarser, it requires more soaking, but is easier to draw, and produces much more and stronger hemp. What is stored must, when wanted to be wrought, be soaked, peeled, washed, and in general treated as before said. In cold weather it takes long soaking."

M. Marcandier is of opinion that the finest and clearest water is always the best for steeping hemp; and he approves of the method of those who make a kind of ditch on the edge of a river, where the water being more still and warm, ferments easily, and penetrates more quickly the parcels of hemp that are laid in it. When they are taken out of this ditch, it will be sufficient to wash them in the current of the river, which will carry off all the gum and mud that would otherwise cleave to them. He holds, that the hemp which has been steeped in rivers is always whitest, and of the best quality; and that that which has lain in ditches, pools, or reservoirs of standing water, is always of a bad colour, has a very disagreeable smell, is loaded with dirt, and loses a great deal in the dressing. These are M. Marcandier's sentiments on this subject, and if they are the result of his experience, as I presume them to be, I cannot but regret his not having related the particulars of his experiments.

The judiciously accurate-Memoirs of the Society which the illustrious states of Brittany have established for the improvement of Agriculture, Commerce, and Arts, are more particular in this respect, and consequently more satisfactory. After observing, that it is still undetermined whether hemp ought to be steeped in running or standing water, that each cultivator of this plant gives the preference to the method he has been used to follow, and that naturalists have not yet written any thing decisive on the choice of the waters fitted for this preparation, the most important of any that hemp undergoes, because it is on this that the ease and goodness of the heckling, spinning, and fabricating in a great measure depends; the Memoirs, I say, of these zealous patriots inform us, that one of the members of their office at Rennes, thought that this diversity of opinions and customs might proceed from running water's being, in fact, always preferable in some cases, and from standing water's being always the best in others. For example; in cold and rainy years, the plant must be weaker, longer green, and fuller of juice, than in dry years, in which last the hemp will be stronger, but at the same time harder and more woody. Why then, say they, very judiciously, should it be expected that the same waters applied to such different productions, should have a similar effect upon each?

To remove all doubt in this respect, the Society ordered some hemp to be pulled in different parts of the province of Brittany, and in different states of growth. Some was pulled before it was ripe, some exactly when it was ripe, and some several days after it was ripe. Each of the parcels of these three sorts of hemp was divided into two equal parts, one of which was laid to steep in running water, and the other standing water. They were afterwards heckled with very great care, and examined with the most scrupulous attention by a person thoroughly acquainted with the defects and good qualities of this commodity.

Minute accounts of every circumstance attending those experiments, and of their result, were sent to the office at Rennes; and the Society, sensible of the vast importance which the ascertaining of this point may be of in many respects, desired that they might be repeated in one and the same year on the hemp of all the districts of the province, and the result of their first experiments was as follows:

1. There was a sensible difference between the same hemp pulled in the three states before mentioned.
2. All the hemp that was steeped in running water, was incomparably whiter than that of the same quality which was steeped in standing water.
3. The hemp which was pulled before it was ripe, acquired the greatest degree of whiteness.
4. The whole of the loss of substance, upon summing up the waste occasioned by each particular preparation, was least upon the whitest hemp; but that which had been steeped in standing water, yielded a greater quantity of fine fibres, and the great losses in point of quantity fell upon the dressing.
5. The hemp which was judged to be the best before it was heckled, did not always preserve its superiority when heckled. That which was at first looked upon as only of a middling, or even of an inferior quality, proved to be the finest and best after it was heckled. This observation

ervation is of great importance, especially when the hemp is intended for naval uses.

"We shall not, add these truly intelligent patriots, limit our inquiries to a bare repetition of these experiments. We purpose to extend them further, in order to have facts which may be entirely relied on. We shall cause the best hemp and best prepared of each different kind of hemp to be spun by the same hand, into as small and fine threads as the hemp is capable of affording, that so we may judge to which of the different manners of steeping this plant the preference is due, by the greater division of which its fibres may be susceptible. These threads shall be exactly weighed, and shall undergo similar preparations in exactly similar leys; after which they shall be weighed again, in order to judge of their goodness by the diminution which each shall have suffered in the leys, and by the degree of whiteness which each of them shall acquire. These experiments, though extremely useful in themselves, are, however, only introductory to a greater enterprize: they will lay a sure foundation for the improvement of every manufacture of hemp, and particularly of sail-cloth, which is an article of the utmost importance to all commercial nations."

The Memoirs of the Royal Society of Agriculture at Tours, for the year 1761, prefer river-water, especially that of rivers which run upon a bed of sand, as the best for steeping of hemp; because this water, being clear, renders the colour of the hemp brighter than it would otherwise be, as there is not any filth therein to sully it: and it peels the more easily when so steeped, not being there liable to so great a degree of putrefaction, as to break the cohesion of the fibres of its bark. It is not, however, here meant, that the hemp should be steeped in the bed of the river, because the inequality of the motion of the water on the sides, and in the middle of the hemp, would prevent the arising of that equal degree of putrefaction which is in this case essentially necessary. On the side of such rivers, a hollow should be dug three or four feet deep, and proportioned in extent to the quantity of hemp to be watered.

As it is contrary to law that the places for steeping hemp be made in running-water, it would be of advantage to contrive them so that the waste-water from the steeping places should run off upon pasture-grounds: because the quantity of putrid vegetable matter which the water wherein hemp has been steeped carries along with it, would greatly enrich those grounds; and with this view likewise all the water of pools or other places used for the steeping of hemp, should be thrown out of them upon the grass, as soon as the hemp has been removed.

It is essential to take heed, that the hemp be not, by any means, laid to steep in water in which there are any animals that might be apt to gnaw it: for these would cut asunder, and totally destroy its fibres. Of this kind are, in particular, those creatures which some people call fresh-water shrimps.

The common method of judging when the hemp has been sufficiently steeped, is by trying whether the bark parts easily from the reed, and can be peeled off its whole length without breaking; for in this case it is thought to have been watered enough. However, it must be allowed, that long practice enables the peasants who cultivate hemp to give it, generally, a due degree of steeping, though they do sometimes mistake: and it is also to be observed, that it is the constant custom of some countries to steep their hemp more than others. But the surest way of all to distinguish whether the hemp has been steeped enough, is, as the Tours Memoirs remark, to take some of the stems out the water, and then to try whether the extremity of the roots snaps off short, and whether the bark separates clear from the reed, its whole length: for in these cases it is certain that the hemp has been sufficiently watered, and it should then be immediately taken out. If the bark does not separate equally, but stops chiefly at the small knots which appear on the stem, this shews that it has not been steeped enough.

The usual duration of the steeping of the male hemp is from three to six days, according to the weather; and of the female hemp, from five to eight or ten days: but as only a small degree of too much or too little steeping is equally hurtful, the utmost attention should be exerted to hit the precise time of its being duly watered.

Some injudiciously neglect to wash the hemp when it is

taken out of the water, because, say they, the filth brought out of the water with it will afterwards fall off: but, in the drying of the hemp, this filth gives it a bad colour, and the dust which arises therefrom is extremely prejudicial to the health of the workmen.

When the hemp, after having been properly steeped, is taken out of the water, the bundles of it should be untied, and spread upon the sand, or upon strong rocky ground; or, if neither of these be at hand, it may be laid upon a field that has been lately reaped, and where the stubble still remains standing. This stubble will keep it hollow, and it will dry the sooner. Some dry their hemp by spreading it out and setting it upright against a sunny wall, or by laying it along the side of a ditch. Grass is not fit for laying it on, because there will arise from thence a moisture which will rot the hemp. For this reason, it is, that the place where hemp is spread to dry, should be as free as possible from every kind of damp. When the hemp is thoroughly dry, it is bundled up again, and carried home, where it should be kept in a very dry place till it is wanted for peeling or breaking.

The method of peeling hemp is so simple, that a description of it would be needless; even children, and the aged and infirm may perform it with ease, by only taking one stalk after another, breaking the reed, and slipping off the bark. This may likewise become the employment of every person belonging to the farm in winter evenings, and at such times as the weather will not admit of their working without doors. It must however be allowed, that there are some inconveniencies attending this method: the peeled hemp comes off in ribbands, which do not answer in the heckling so well as that which has been broken; more of the useless membranes, especially towards the root, still adhere to it, and, by increasing its weight, render it, to use the common saying on this occasion, better for the seller than the buyer; besides which, the hemp does not always peel off in equal lengths, and from thence arise considerable disadvantages, and loss in its future dressings.

The hemp which is to be broken should first be rendered very dry; because the reed will then be the more brittle, and therefore part the more easily from the bark. There are several ways of drying. Messieurs Du Hamel and Marcandier describe a kind of cave or cavern, in which it is commonly dried in many parts of France. This cavern is generally six or seven feet high, five or six feet wide, and nine or ten feet long. A hollow under a rock is often properly made use of for this purpose; but as that cannot always be met with, it frequently is necessary to have recourse to art. In this case, some form the top of their vault with dry stones, others cover it with broad flat stones, and others again only close it with pieces of wood, over which they lay a quantity of earth sufficient to stop up all the interstices: but which ever of these methods is taken, the drying place should be so situated as to be sheltered from the north and north-east winds, and be open to the south, that it may receive the benefit of the sun; because the usual season for breaking of hemp is in clear frosty weather, when the business of the field is suspended.

At about four feet above the floor of this drying place, and two feet from its mouth or entrance, three bars of wood, about an inch thick, are placed across the cavern, from side to side, and there fixed. On these bars is laid, about six inches thick, the hemp that is to be dried. A careful person, which generally is a woman, then keeps constantly burning, under the hemp so laid, a small fire made of the fragments of the reeds of hemp that has already been broken or peeled. The person thus employed must be extremely watchful, because, as this kind of fuel is soon consumed, and must of course be frequently replenished in order to keep a constant and regular fire all over the hearth (for this is absolutely necessary) very great care must be taken that the flame do not ever rise so high as to set fire to the hemp, which is exceedingly combustible, especially after it has been dried some time. The same person takes care also to turn the hemp from time to time, in order that it may be dried equally in all its parts; and likewise to put on fresh hemp, when the former is dry enough to be taken away and sent to the break.

Where but a small quantity of hemp is to be dried, an oven is doubtless the safest method; and when the hemp is dressed at home, it may perhaps be dried as fast by this means,

means, as the other avocations of the family will admit of its being wanted. The only attention requisite in this case, is that the oven be not so hot as to endanger the fine and tender fibres of the hemp: for too great a heat may not only scorch them, but likewise so parch the oil in the hemp, as that the hemp will afterwards remain harsh and dry, and not be so easily whitened as it might otherwise be.

It also is usual, where the quantity of hemp is greater than can be managed with an oven, to dry it on a kiln; and this is a good method; provided the fire here be also very moderate, and made of such materials as do not blaze or sparkle, because of the great aptness of dry hemp easily to take fire. Coke is perhaps the very best fuel that can be used for this purpose.

The operation of breaking hemp, by which general term is however strictly meant only the breaking of the reed, which some call the bunn, or woody part of the stem, within the bark; for the bark itself, of which is made the filamentous substance that is spun and used in manufactures, only bends under the hand of the dresser, and does not break: this operation, I say, has hitherto generally been executed three ways, namely, by beating the hemp with beetles, which is a laborious and tedious work; or by the Dutch hand-break, which is in every respect much preferable to the beetle; or by fluted rollers worked by horses, wind, or water, but of choice by the latter, where a running stream can be procured. This last is more expeditious, and less laborious than either of the other ways; but is dangerous to the workmen employed therein, because, if by any inadvertence the rollers should catch hold of their fingers, the loss of a limb at least is inevitable. The only means of preventing this dreadful consequence, in such a case, is to have an iron crow at hand, ready to clap instantly between the rollers, as is practised in sugar works, which are of a similar construction.

The fluted rollers are undoubtedly the best instrument for breaking hemp, because the length of the stalk and strength of the reed of this plant must render the Dutch-break a very tedious operation, especially when large quantities of hemp are raised, as must be the case wherever a sufficiency of it is cultivated to answer the purposes of the great and important manufactures in which it is employed in this nation.

The Moravian hemp mill, used in America, is also a good instrument. It consists of a large heavy stone, shaped like a sugar loaf, with the small end cut off. A body of that form will go round in a circle, if it be moved, on a plane. This is moved by a water mill, and the hemp, being laid on the floor, in its way, is bruised by the weight of the stone passing over it.

After the hemp has been broken, it undergoes a second operation, which is commonly termed swingling or scutching. The intention here is to separate the reed from the hemp, and this is done by one or other of the following ways. In the first, the workman takes a handful of hemp in his left hand, and holding it over the edge of a board, strikes it with the sharpened edge of a long, flat, and straight piece of wood, commonly called a swingle hand, or scutcher. The author of the thirty-seventh letter in the Dublin Societies Weekly Observations recommends that the cutting edge of the scutcher be made of a circular form, in order that its greatest force may fall on the middle of the hemp, and thereby spread it, by which means it will be the more equally cleared of the remaining broken pieces of the reed. But this method is, at all events, very laborious and tedious; and therefore water mills have been erected, in which several scutches, fixed in the same axle-tree, are moved with great velocity. Here the work is performed with great expedition, and much less fatigue to the workmen; but a greater waste is made of the hemp, owing to the velocity with which this engine is turned.

Before the hemp thus prepared is heckled, it usually undergoes a third operation, called beetling, the design of which is to loosen and thereby more thoroughly separate its fibres. The beetles used for this purpose are moved either by hand or by water.

We have already described the instruments invented by Mr. Macpherson for performing these operations with very great facility, under the article FLAX, and therefore need not be repeated here. See the article FLAX.

Mr. Marcandier proposes, instead of scutching and

beetling the hemp, to give it a second steeping after it has been peeled or broken, the better to soften the bark that may still remain hard, and not be easily brought to a proper degree of fineness. For this purpose, the hemp intended to be steeped a second time, is divided into small parcels; these are tied loosely round the middle with a piece of packthread, in order that they may be managed easily without mixing or entangling them; and the hemp thus tied is laid in a vessel filled with water, where it is left, more or less time, according to the hardness of its fibres, and the quantity of glutinous adherent matter remaining on it. Three or four days are always sufficient for this purpose: but a less time will do, if the hemp wants only to be cleared of that adherent matter. When it has been thus steeped long enough, it should be washed very clean in a running stream; and if many of the fibres of the hemp are found to cling together in what our author calls ribbands, he advises to beat them in the manner that linen is beaten in bleaching.—It is safer to err in too little, than in too much steeping; because, after the fibres have been loosened in the break, they will be the more liable to be destroyed by even only a slight degree of putrefaction. When the fibres of the hemp are sufficiently disengaged from each other, they seem, while immersed in water, to be as completely dressed as if they had already passed through the heckle. After this watering, the parcels are opened, spread on a board, and laid in the sun to dry.

M. Marcandier observes farther, and likewise from his own experience, that after this preparation, the hemp may be again steeped and washed in a lye of pot-ash or wood ashes, rendered perfectly clear of all filth. This will undoubtedly contribute to the removing of any such matter still remaining in the hemp, as must necessarily fall off in the future preparations, before the manufacture made of the hemp is fit for use. And, indeed, a lye of this kind bids fair to be of service in the preparing of flax as well as hemp; because, both being thereby perfectly freed from every particle which must otherwise fall off in the future operations of heckling, spinning, bleaching, &c. the cloth or other manufacture made of them will be proportionably better and more durable. The time taken up in bleaching will, in particular, be very much shortened thereby.

In the whole of this process, the water should be warm, because warm water acts more powerfully than cold in dissolving the impurities which are to be separated from the hemp; and it is also an indulgence to the people employed in this business, who might otherwise be more apt to slur over their work. It will therefore be most advisable to perform this operation when the weather is moderately warm, thereby to save the trouble and expence of making fire to warm the water or the lye.

M. Marcandier having experienced the efficacy of horse-chestnuts in the bleaching of linen and cleansing of woollen stuffs, made likewise use of a solution of them in water, as a lye for preparing hemp in the manner above described. The method of preparing this lye is as follows: the chestnuts are peeled, and then rasped, as fine as possible into soft water, in the proportion of two, or, at most, three nuts to every quart of water. This is done ten or twelve hours before the mixture is to be used, and in the mean while it is stirred from time to time, the better to dissolve these raspings and impregnate the water. The last stirring is given a quarter of an hour at farthest before the water is drawn off from the coarser part of the raspings, which sinks to the bottom; and this is done, either by inclining the vessel and pouring the lye off gently into another, or by lading it out by hand, while the water is yet white, and froths like soap-suds. In order to use this lye, it is made rather hotter than the hand can well bear, and the hemp is then steeped and washed in it, as in soap-suds.

The hemp thus prepared is carefully dried, laying the fibres smooth and as little intermixed as possible. When dry, it is doubled and twisted at the ends, or tied up in bundles. The farther business of the hemp-dresser need only be an easy beating of the hemp, and that chiefly to separate the fibres that may have clung together in the drying, and to the common operations of the heckle. The dangers so often fatal to the dressers of hemp from the dust drawn in with their breath, will also be hereby in a great measure avoided: and the hemp thus prepared will be white, smooth, soft, and flexible.

The same author extols highly the various uses to which hemp thus prepared, and even its tow, or what is separated from

from it by the heckle, may be applied. This hemp, he informs us, may be died like silk, wool, or cotton, and may be made into cloth, stuffs, and garments of all kinds; and that a great advantage attending the use of this material is, that it will not be in danger of being destroyed by those worms which eat woollen cloth. These advantages attending hemp prepared in the manner which M. Marcandier has proposed, may well deserve the farther experiments and attention of our manufacturers, especially at Manchester, or wherever else our mixed stuffs are made.

HEPS, the fruit of the species of wild rose, generally written hips.

HERBAGE, grafs; pasture in general. It is also used to signify the title and right of pasture. See **GRASS**.

HERD, a number of beasts together, generally black cattle.

HERDSMAN, a keeper of herds, one employed in tending cattle.

HERRING SCALES, for manure. Mr. Young, in his *Annals of Agriculture*, Vol. III. says, "besides other kinds of manure, the Lestoff farmers use herring scales. The herrings are washed in large tubs, previously to their being smoked, and what scales come off in the operation, are sold to the farmers at 6d. the last; that is the scales of 10,000 herrings.

"These scales are sown upon wheat on clover lays, and harrowed in with the corn; and from such treatment the crops are thought to receive considerable advantage.

"And might not then, from the same source, an additional benefit be derived? the water in which the herrings have been washed is oily, bloody, and strongly impregnated with the effluvia of the fish. Now this water might be received into reservoirs contrived at no very great expence: from these it might as occasion served, be drawn and conveyed in watering carts (such as are in use about London to water the roads) either immediately to the fields that are in a proper state to receive it, or to a heap of sods intended for compost. Sods for this purpose are preferable to dung, either rotten or fresh; for they will absorb the moisture, whereas rotten dung is too compact to admit it, and too rich to want it, as for that which is not yet rotten, much wet prevents the process of the fermentation, which is necessary to convert it into manure.

"The probability of any good arising from the use of such water, is grounded, I confess, upon nothing but that of the scales above mentioned: yet, if upon the authority of the Lestoff farmers we admit the utility of the practice, the presumption is very much in favour of the hint which is here submitted to the consideration of the experimental farmer living in the vicinity of a fishing town.

Before any great expence is incurred, let a small open spot of ground, of equal goodness throughout, be appropriated to the trial; of which, if one half receives a common dressing, and the other this alone from a watering-pot, the produce of each will decide upon the respective merits of the two modes, and plainly evince what degree of attention is due to the latter."

HIDE, the skin of beasts, but particularly applied to those of large cattle, as bullocks, cows, horses, &c.

HIDE of Land, was such a quantity of land as might be ploughed with one plough within the compass of a year, or so much, as would maintain a family; some call it sixty, some eighty, and some an hundred acres.

The distribution of this kingdom by hides of land is very ancient; mention being made of it in the laws of king Ina. Henry I. had three shillings for every hide of land, in order to raise a dowry for his daughter: this tax was called hidage.

HIDE-BOUND, a distemper in horses, when the skin sticks so fast to the back and ribs, that the hand cannot separate the one from the other, without great difficulty; his body is at the same time lean, his back-bones stand up, his guts are for the most part deficient in moisture, and his dung dry, and more offensive than common.

If a horse becomes hide-bound by hard-riding and ill keeping, he may be cured by good keeping. If it be the effect of a fever, or some other disease, if that be cured which is the cause, the effect will cease; but if he has no fever upon him, and he is hide-bound only from lowness of blood and spirits, give him boiled barley, white-water, or the like, and when his flesh is raised, harden it with good oats, beans, and moderate exercise.

Taplin recommends as a cure, to take away a small quan-

tity of blood, and in three or four hours after increase its impetus by a mash of malt, oats and bran, equal parts; continuing it every night for a fortnight, stirring in two ounces of flour of brimstone every other night; giving his other feeds morning and noon, equal parts of oats and bran with half a pint of old beans in each, to prevent relaxing the body too much by the mashes.

HILL, an elevation of ground, less than a mountain; a down.

HILLOCK, a little hill.

HIP-SHOT, is when the hip-bone of an horse is removed out of its place; this happens to a horse many ways; by a wrench, stroke, or slip, strain, sliding or falling.

The signs to know it, are, the horse will halt, and go fideling, and the fore-hip will fall lower than the other; nay, in time, the flesh will consume away; so that if it be let alone too long, it will never be cured.

HIVING of Bees, the placing a swarm of bees in a hive, in order to have the benefit of their labours. See the article **BEE**.

HOE, a tool made like a cooper's adz, to cut up weeds in gardens, fields, &c. This tool is commonly called the hand hoe.

This instrument is of great use, and should be more employed in hacking and clearing the several corners, cracks, and patches of land, in spare times of the year, which would be of no small advantage thereto.

Horse Hoe, a large kind of hoe, drawn by horses, and used to stir the intervals in the New Husbandry, and clear the corn from weeds.

Under the article **CULTIVATOR**, we have described the instruments used abroad for this purpose; and shall here give two very useful instruments of the same kind, invented by the ingenious Mr. Hewitt, who presented them to the Society for the Encouragement of Arts, &c. where they may be seen. The following letter, describing these instruments, was sent by the inventor to the Society.

GENTLEMEN,

Perusing the Essays on Husbandry, I observed particularly, that the author, page 105, expresseth hopes of seeing some "new invented plough, cheap, simple, and rightly calculated for destroying weeds; keeping plants clean; and stirring the ground;" and, page 106, further says, "now as most people prefer useful, and cheap, to elegant and expensive inventions, it is natural to wish for a hoe plough entirely simple, and not costly. For the mechanism of those devised hitherto, by the ingenious lovers of agriculture, is of so perplexed, and complicate a nature, that it will no ways answer the common purposes of husbandry: but, being perpetually out of order, will throw the poor ploughman into despondency; and the rather, as neither he, nor the country plough-wright, can comprehend how to rectify any defects, or accidents, except with extreme difficulty."

The very name of a hoe-plough suggested the idea of an instrument, which I shall call a horse-hoe; whose construction is intirely new, simple, and much less costly than a common plough, such as country plough-wrights, and smiths, are able to make; and such as common ploughmen are able to use: and which seems, according to the hopes of the aforesaid author, to be rightly calculated for destroying weeds, keeping plants clean, and stirring the ground.

This horse-hoe, a model of which I beg leave, in the most respectful manner, to present to this honourable Society, I hope may be of very extensive use in agriculture as it must be much more efficacious, and expeditious too, than any kind of hand-hoe for the destruction of weeds, and stirring the ground. For if the instrument does not cut below the crown, or head, of the roots, such roots will sprout again, and the first labour become fruitless; which indeed is too often the case of hand-hoeing: as the labourer, sometimes only scratches the surface of the earth, and shaves off the leaves of the weeds, the roots remaining intire and unhurt, to vegetate again. With this instrument the husbandman may hoe the ground so deep, that it will infallibly cut asunder the roots of every weed it meets with, below the crown or head: and consequently, either destroy them, or at least greatly check their future growth that season.

This instrument is calculated for hoeing in the intervals between the generality of plants in straight rows: such as trans-

transplanted lucerne, beans, peas, and turneps, sown with a drill plough, &c. In large gardens, hop-grounds, nurseries and plantations of young trees, much labour and expence in hand-hoeing, may probably be saved by the use of it.

In the county of Norfolk (and probably in many other places) the husbandmen, in the months of March and April, preparing their lands for barley, generally give them a certain number of earths, according to the phrase of that country; or, in other words, plough them a certain number of times. In those months the weather is frequently very dry: and the soil being turned over and over again, and exposed to the sun and wind, becomes so dusty, that a great part of the seed will not grow without rain; which sometimes not falling in many weeks after the seed time, causeth the crop to consist of different growths; so that when the first grown crop is ripe for the scythe, the latter is but just eared. This evil, perhaps, may, in some measure, be remedied by the use of this horse-hoe, instead of the common plough, at that season; for this will stir, and loosen the earth as effectually, as the other: and at the same time, neither remove, nor turn it over, which seems to be beneficial, in a drought, upon very light and sandy soils.

With respect to foul summer fallows too, it may be of singular service. The common plough buries the weeds, of which many grow again. This horse-hoe will cut their roots asunder, below the surface of the earth; and by leaving their foliage above it, exposed to the summer sun, the greatest part of them will wither and die: so that they will not give the husbandman much more trouble the remaining part of the summer. And, as this hoe may be eighteen or twenty inches broad, two acres of land may be hoed by it, as soon as one acre can be ploughed, by the common plough.

This new instrument is intended for public benefit; and to the consideration of the public, as well as of this honourable Society in particular, it is freely submitted. If it be judged an useful implement in husbandry, well; if not, the pleasure that has arisen from the hope of doing good has amply rewarded, for his trouble, the inventor, who has the honour to subscribe himself,

Gentlemen

Hadleigh,
April 19, 1766.

Your most humble,
and obedient servant,

WILLIAM HEWITT.

P. S. Since I had completed this model, I apprehended, that its utility might be rendered still farther extensive, by a very small alteration; therefore, gentlemen, I take the liberty of laying before you another model, calculated for hoeing the furrows between wheat ridges, which all farmers acknowledge to be very good husbandry, though many of them are deterred from the practice of it, for want of a cheap expeditious method of putting it in execution. An instrument of this kind I am persuaded, will very greatly expedite that useful work; and if it meets with your approbation, gentlemen, many lovers of improvement in agriculture may be induced to give it a fair and impartial trial.

An explanation of the HORSE-HOE, Plate XVII. Fig. 3.

A represents a small round curved iron-bar, fixed upon each end of the axle of the wheel, by which the horse-hoe is drawn.

B, the wheel three feet in diameter.

C c two flat iron bars, three feet long, fixed upon the axle of the wheel, at D d, and to the sides of the hoe; at E e, by bolts and screws: upon these bolts, as well as the axle of the wheel, they are moveable.

F, a small round iron-bar, fastened at each end, into the two bars; C c (to strengthen them) at G g, from and to G, these bars may be straight. From G to E, let them be curved.

H, the hoe itself; the breadth of which may vary according to the different distances of the rows of plants, whose intervals are to be hoed.

K K, two little flat curved iron-bars, fixed by bolts, upon which they are moveable, to the bars C c. Each of them

pass through a staple, fixed into the sides of the hoe at L l. In both these little bars is a row of holes. In each of the staples, is one hole; and, directly opposite to them, one hole in each of the sides of the hoe: and, by means of two bolts, passing through these holes, and some of the holes in the bars K K, the hoe is fixed to any position; so that the ground may be hoed as near the surface, or as far below it, as is necessary.

M M, two wooden handles, fixed to the two sides of the hoe, and to each other, by the cross bar O; as long and as high from the ground, as the handles of a common plough.

Figure 4, represents the horse-hoe, intended for hoeing the furrows, between wheat ridges: which differs only, in one respect from the other. That hoe is flat; this is curved. The breadth, and curvature of this must depend entirely upon the breadth and curvature of the furrows, to be hoed. In which respect, every sensible farmer can easily direct the smith how to form it. But, after all, if any persons be inclined to make trial of this instrument, I would advise them not to trust to a verbal description, but to send for a model of it to Thomas Tillet, a very ingenious smith at Hadleigh in Suffolk.

This hoe is ingeniously contrived, and serves very well to cut the weeds near the surface of the ground; but none of the broad hoes can go deep, and in that respect, are deficient in one of the purposes of hoeing, namely, to improve the land; which cannot be done in any great degree, but by deep tillage: for which reason, when this, or any other broad hoe is made use of to cut the weeds near the surface of the ground, another instrument should follow that goes deeper. It is no recommendation of this or any hoe, that it neither removes the earth, nor turns it over: for turning it, and exposing a new surface to the influences of the atmosphere, is one of the principal means of fertilizing land, as is found by experience, in the practice of the New Husbandry.—For this reason also, this instrument is improperly named a plough; for the idea of a plough, is not only to raise a furrow, but also to turn it; neither should any instrument be named a hoe-plough, or horse-hoe; these names being given to the plough invented at first, to be used in the New Husbandry for deep hoeing; and generally continued to be so called by the practisers of that husbandry. Other hoes, that are drawn by horses, may, more properly, and by way of distinction be called cultivators.

The *Double Hand-hoe*, Mr. Marshall says is one of those petty simple, cheap implements, which the more they are used the more obvious their merit appears. The whole cost of wood and iron-work is but three or four shillings, and with a trifling expence of laying the blades, it will last a man's life-time; but it is fitter for a light pea-soil, than a stiff bean-soil.

Mr. Marshall, in his *Rural Economy of the Vale of Gloucester*, says "the hoeing of crops in general has long been held out as a thing most desirable, in the arable process. Here we find it nearly in full practice. Not only the leguminous crops, which are planted in rows; but wheat, which is sown at random, are hoed: not by a few individuals only, but by husbandmen in general; the wheat crop being hoed, here, as customarily as the turnep crop is in Norfolk. Barley may be said to be the only crop, which is not hoed. But this crop is invariably fallowed for; either by a whole year, or by a winter-and-spring fallow; so that every crop which is taken, is, in reality, a fallow crop."

"Hence we see fields which have borne crops of grain, year after year without remission, during time immemorial, still affording annually portions of produce, which, in the management of some individuals, in some seasons, may be entitled to the name of crops. A fact, which nothing less than actual observation, could have induced me to give full credit to. A fact which proves, in a most interesting manner, the value of a due attention to crops while vegetating: a species of attention, which, in the management of the kingdom at large, is entirely omitted; excepting, perhaps, what is bestowed on an imperfect hand-weeding: in general terms, it may be said, that, in most other districts, crops remain in a state of neglect, from seed-time to harvest. While, here, the business of the arable process does not appear to be set about in earnest, until the crops be above ground."

"The origin of this unparalleled attention to crops, while vegetating, would now, perhaps be difficult to trace. In all probability, it originated in a kind of necessity, on the

Cooke's *Patent Drill Machine* improv'd & simplified
and capable of being converted into a *Horse Hoe*.

the every years lands; which, without it, must long ago have been wholly possessed by one continued thicket of weeds. Its good effect being there seen, it would be received, by degrees, into the fallow fields: first as an expedient to save a foul crop; and, at length, as a practice:

"The excellency of this custom, and the extent of its utility, are not confined to the field: the hoeing of corn is done, chiefly, by women and children: industry is, of course, encouraged; and the parish levies probably lessened; or, what is equally beneficial to the farmer, the wages for men's labour are lowered: while, in the saving of seed, by this practice, the farmer and the community are still more immediately benefited."

HOEING, the breaking or dividing the soil by tillage, while the corn or other plants are growing thereon.

It differs from common tillage, which is always performed before the corn or plants are sown or planted, or in the time of performing it; and it is much more beneficial to the crops than any other tillage. This sort of tillage is performed various ways, and by means of different instruments. Land which, before the tillage, would have yielded little, though the more it is tilled before sowing, the more plenty of corn it yields; yet, if tilled only before the sowing, will always have some weeds, and they will partake of the advantage of the tillage as well as the corn. This is one reason for an after-tillage, such as that by hoeing. But there is another consideration that yet more requires it; this is, that as soon as the ploughman has done his business, by ploughing and hoeing the land, after sowing, the soil, of its own accord, begins to undo it all again by tending towards its original texture and specific gravity again; the altering of which was the only business of all the former tillage. The breaking the particles of the earth, and making in it new pores, and new particles or new surfaces, is the great business of the plough and harrow; but, as soon as their use is over, the earth begins to coalesce again into its own form, the particles unite together, and the artificial pores in a great measure close up. The seed is nourished in a worse ground than it was first put into, and the more the plant grows up, and requires a larger supply of food, the worse the pasture becomes. While nourishment is thus denied the growing plants, they are at the same time choked with weeds, which being of a hardier nature than grain will grow with less supplies, and therefore thrive more vigorously, and rob them of a great part of the little food the land before allowed them.

Farmers in all ages have been acquainted, in some degree, with the use of tillage and dung to crops of useful plants; but they have so ill managed the time of giving these assistances to nature, that there is no doubt but one third part of the nourishment raised by dung and tillage, if it were given to plants and corn at many proper seasons, and proportioned to the different times of their exigencies, would be of more benefit to the crop than the whole is, when applied all together at the time of sowing.

Nature, by what she does in the animal œconomy, seems to point out to us something like the remedying this by hoeing; for when the teeth, as the plough, have tilled that soil or mass which is earth altered; and when the saliva and the juices of the stomach have served to divide and attenuate it, as the salts of dung and other manure do land; after all this, the bile and pancreatic juices are ordained to farther attenuate it, at the very time when it is ready to be exhausted by the numerous mouths of the lacteals, situate in the intestines. This last operation of these juices seems analogous to the meliorating the soil by hoeing, after the plants are grown, and are becoming fit for use.

Transplanting is nearly allied in its nature to hoeing, but it is much inferior. The nature of this will not admit of its being a general thing; and even if it would, hoeing is better: for by transplanting, the plants can only be kept up to a certain period, after which they will not bear it; but hoeing may be used to them with advantage, to their utmost standing, and make them vigorous all the while.

The roots of a plant are all necessarily broken off in transplanting, and it requires some time for it to strike a whole set of new ones; and if the earth about it is not kept thoroughly moistened all this time, the new formed-roots will not be able to shoot, and the plant will starve in the midst of plenty: but, on the contrary, in hoeing, the same advantage of a new pasture for the plant is obtained, by the breaking the particles of the earth, and at the same time no more of the roots are broken off than can easily be supplied, and the rest remaining in their places, the plant

continues growing without that stop or decay, which must happen on transplanting, and which it recovers only by degrees. It is observed, that some plants are the worse for transplanting: lucerne and sainfoin are never so good after transplanting, as when they are left in their native places, at the same distances; and finochia removed, is never so good and tender as when it is not:

This last plant receives such a check from transplanting in its infancy; that it has afterwards a disease like the rickets, which causes knots and swellings in it, that spoil it as a delicacy. All the tap-rooted plants suffer by transplanting; for it is necessary in this to cut off the long main-root, which afterwards, however good the soil may be, never arrives at the length it otherwise would have had, and which was necessary for the success of the plant.

Mr. Young, in his *Annals of Agriculture*, vol. xiv. gives the following

Description of a Patent Drill Machine, with a Six-Share Horse-Hoe annexed, and comprised in one and the same Instrument, under a new Patent: also a simple Hand-Hoe, invented by the Rev. James Cooke, White Lion Yard, opposite the Pantheon, Oxford-Street, London. See Plate, xviii.*

"The superior advantages of the present improved drill, compared with the old one, chiefly consist,

"1st, In the wheels (B B, fig. 1.) being so large that the machine can travel on any road without trouble or danger of breaking; also from the farm to the field, &c. without taking to pieces; requiring only half the draught which the old machine requires.

"2d, In the coulter-beam (C C, fig. 1. with all the coulters), moving with great ease, on the principle of the pentagraph, to the right or left, so as to counteract the irregularity of the horse's draught, by which means the drills may be made straight: and where lands or ridges are made $4\frac{1}{2}$ or $9\frac{1}{2}$ feet wide, the horse may always go in the furrow, without setting a foot on the land, either in drilling or horse-hoeing.

"3d, In the seed supplying itself regularly, without any attention, from the upper to the lower boxes as it is distributed.

"4th, In lifting the pin (M) on the coulter-beam to a hook (L) on the axis of the wheels; by which means the coulters are kept out of the ground at the end of the land, without the least labour or fatigue to the person who attends the machine.

"5th, In going up or down steep hills, the seed-box is elevated or depressed accordingly, so as to render the distribution of the seed regular; and the seed being covered by a lid, is screened from wind or rain.

"These are some of the advantages appertaining to the above improved drill, which though considerable in the process of drilling, are as nothing, compared with those which arise from the use of the horse-hoe; of which it shall suffice me to say, that from eight to ten acres of land are commonly hoed in one day, with one man, a boy, and one horse, at the trifling expence of 6d. or 8d. per acre, in a style far superior to, and more effectual than any hand-hoeing whatever, also performed at times and seasons when it is impossible for the hand-hoe to be used at all.

"From last year's official proofs and extensive experiments in horse-hoeing, I am justified in saying, that, by a proper and seasonable use of the above drill and horse-hoe, the largest farm in this island may be kept as clean from weeds (the bane of all arable lands) as any garden need be, with a clear extra profit of more than the rent of land.

"A A, fig. 1. Shafts of the machine, applied to axis of the wheels, so that the horse may go on the land, or in the furrow without setting a foot upon the land, either for the purpose of drilling or horse-hoeing.

"B B, the wheels.

"C C, coulter-beam, with holes or mortices for the coulters at different distances.

"D D, handles of the machine, applied to the coulter beam, also to the axis of the wheels, by hooks and eyes, or staples.

"E E, upper seed-box in partitions, covered by a lid, to protect the grain or seed from wind or rain.

"F F, lower seed-box in partitions.

"G G, slides between the upper and lower seed-boxes, for regulating the quantity of seed sown.

"H H, cylinder with cups or ladles of different sizes, for

*Cooke's Patent Drill Machine improved & simplified
and capable of being converted into a Horse Hoe.*

the every years lands; which, without it, must long ago have been wholly possessed by one continued thicket of weeds. Its good effect being there seen, it would be received, by degrees, into the fallow fields: first as an expedient to save a foul crop; and, at length, as a practice.

"The excellency of this custom, and the extent of its utility, are not confined to the field: the hoeing of corn is done, chiefly, by women and children: industry is, of course, encouraged; and the parish levies probably lessened; or, what is equally beneficial to the farmer, the wages for men's labour are lowered: while, in the saving of seed, by this practice, the farmer and the community are still more immediately benefited."

HOEING, the breaking or dividing the soil by tillage, while the corn or other plants are growing thereon.

It differs from common tillage, which is always performed before the corn or plants are sown or planted, or in the time of performing it; and it is much more beneficial to the crops than any other tillage. This sort of tillage is performed various ways, and by means of different instruments. Land which, before the tillage, would have yielded little, though the more it is tilled before sowing, the more plenty of corn it yields; yet, if tilled only before the sowing, will always have some weeds, and they will partake of the advantage of the tillage as well as the corn. This is one reason for an after-tillage, such as that by hoeing. But there is another consideration that yet more requires it; this is, that as soon as the ploughman has done his business, by ploughing and hoeing the land, after sowing, the soil, of its own accord, begins to undo it all again by tending towards its original texture and specific gravity again; the altering of which was the only business of all the former tillage. The breaking the particles of the earth, and making in it new pores, and new particles or new superficies, is the great business of the plough and harrow; but, as soon as their use is over, the earth begins to coalesce again into its own form, the particles unite together, and the artificial pores in a great measure close up. The seed is nourished in a worse ground than it was first put into, and the more the plant grows up, and requires a larger supply of food, the worse the pasture becomes. While nourishment is thus denied the growing plants, they are at the same time choaked with weeds, which being of a hardier nature than grain will grow with less supplies, and therefore thrive more vigorously, and rob them of a great part of the little food the land before allowed them.

Farmers in all ages have been acquainted, in some degree, with the use of tillage and dung to crops of useful plants; but they have so ill managed the time of giving these assistances to nature, that there is no doubt but one third part of the nourishment raised by dung and tillage, if it were given to plants and corn at many proper seasons, and proportioned to the different times of their exigencies, would be of more benefit to the crop than the whole is, when applied all together at the time of sowing.

Nature, by what she does in the animal œconomy, seems to point out to us something like the remedying this by hoeing; for when the teeth, as the plough, have tilled that soil or mass which is earth altered; and when the saliva and the juices of the stomach have served to divide and attenuate it, as the salts of dung and other manure do land; after all this, the bile and pancreatic juices are ordained to farther attenuate it, at the very time when it is ready to be exhausted by the numerous mouths of the lacteals, situate in the intestines. This last operation of these juices seems analogous to the meliorating the soil by hoeing, after the plants are grown, and are becoming fit for use.

Transplanting is nearly allied in its nature to hoeing, but it is much inferior. The nature of this will not admit of its being a general thing; and even if it would, hoeing is better: for by transplanting, the plants can only be kept up to a certain period, after which they will not bear it; but hoeing may be used to them with advantage, to their utmost standing, and make them vigorous all the while.

The roots of a plant are all necessarily broken off in transplanting, and it requires some time for it to strike a whole set of new ones; and if the earth about it is not kept thoroughly moistened all this time, the new formed-roots will not be able to shoot, and the plant will starve in the midst of plenty: but, on the contrary, in hoeing, the same advantage of a new pasture for the plant is obtained, by the breaking the particles of the earth, and at the same time no more of the roots are broken off than can easily be supplied, and the rest remaining in their places, the plant

continues growing without that stop or decay, which must happen on transplanting, and which it recovers only by degrees. It is observed, that some plants are the worse for transplanting: lucerne and sainfoin are never so good after transplanting, as when they are left in their native places, at the same distances; and finochia removed, is never so good and tender as when it is not.

This last plant receives such a check from transplanting in its infancy; that it has afterwards a disease like the rickets, which causes knots and swellings in it, that spoil it as a delicacy. All the tap-rooted plants suffer by transplanting; for it is necessary in this to cut off the long main-root, which afterwards, however good the soil may be, never arrives at the length it otherwise would have had, and which was necessary for the success of the plant.

Mr. Young, in his *Annals of Agriculture*, vol. xiv. gives the following

Description of a Patent Drill Machine, with a Six-Share Horse-Hoe annexed, and comprised in one and the same Instrument, under a new Patent: also a simple Hand-Hoe, invented by the Rev. James Cooke, White Lion Yard, opposite the Pantheon, Oxford-Street, London. See Plate, xviii.*

"The superior advantages of the present improved drill, compared with the old one, chiefly consist,

"1st, In the wheels (B B, fig. 1.) being so large that the machine can travel on any road without trouble or danger of breaking; also from the farm to the field, &c. without taking to pieces; requiring only half the draught which the old machine requires.

"2d, In the coulter-beam (C C, fig. 1. with all the coulters), moving with great ease, on the principle of the pentagraph, to the right or left, so as to counteract the irregularity of the horse's draught, by which means the drills may be made straight: and where lands or ridges are made $4\frac{1}{2}$ or $9\frac{1}{2}$ feet wide, the horse may always go in the furrow, without setting a foot on the land, either in drilling or horse-hoeing.

"3d, In the seed supplying itself regularly, without any attention, from the upper to the lower boxes as it is distributed.

"4th, In lifting the pin (M) on the coulter-beam to a hook (L) on the axis of the wheels; by which means the coulters are kept out of the ground at the end of the land, without the least labour or fatigue to the person who attends the machine.

"5th, In going up or down steep hills, the seed-box is elevated or depressed accordingly, so as to render the distribution of the seed regular; and the seed being covered by a lid, is screened from wind or rain.

"These are some of the advantages appertaining to the above improved drill, which though considerable in the process of drilling, are as nothing, compared with those which arise from the use of the horse-hoe; of which it shall suffice me to say, that from eight to ten acres of land are commonly hoed in one day, with one man, a boy, and one horse, at the trifling expence of 6d. or 8d. per acre, in a style far superior to, and more effectual than any hand-hoeing whatever, also performed at times and seasons when it is impossible for the hand-hoe to be used at all.

"From last year's official proofs and extensive experiments in horse-hoeing, I am justified in saying, that, by a proper and seasonable use of the above drill and horse-hoe, the largest farm in this island may be kept as clean from weeds (the bane of all arable lands) as any garden need be, with a clear extra profit of more than the rent of land.

"A A, fig. 1. Shafts of the machine, applied to axis of the wheels, so that the horse may go on the land, or in the furrow without setting a foot upon the land, either for the purpose of drilling or horse-hoeing.

"B B, the wheels.

"C C, coulter-beam, with holes or mortices for the coulters at different distances.

"D D, handles of the machine, applied to the coulter beam, also to the axis of the wheels, by hooks and eyes, or staples.

"E E, upper seed-box in partitions, covered by a lid, to protect the grain or seed from wind or rain.

"F F, lower seed-box in partitions.

"G G, slides between the upper and lower seed-boxes, for regulating the quantity of seed sown.

"H H, cylinder with cups or ladles of different sizes, for different

different sorts of grain or seeds ; by which the grain or seeds are taken up, and dropped into the funnels I I, and conducted thereby into incisions or drills made in the land by the coulters K K.

" L, a hook applied to the axis of the wheels.

" I, a chain applied to the coulters-beam, the last link of which, being put upon the lowest hook, will prevent the tubes of the funnels from being displaced, when the machine is crossing deep furrows or gutters.

" M, a pin of iron projecting from the coulters-beam, which being lifted on the hook L, at the end of the land, will bear the coulters out of the ground, while the machine is turning round, or on any other occasion, without any labour to the person who attends the machine, in supporting them.

" N, a cog-wheel.

" O, a cog-wheel, turned by the wheel N.

" P, a lever and string, passing over a pulley to the axis of the cylinder H, by moving the lever P to the notch in the staple Q, the wheel O will be lifted out of gear with the wheel N, by which means the distribution of grain or seed may be stopped at pleasure, in an instant, at the end of the land, or on any other occasion.

" R, an iron bar with holes in it, by means of which, and a pin going through the holes, the seed-box may be elevated or depressed, so as to keep the lid of the box horizontally level, whether going up or down steep hills, or on level ground.

" S S, two staples in the ends of the seed-box, for the reception of two slips of wood, with canvas to prevent the wind from interrupting the grain or seed ; also to prevent dirt or soil falling from the wheels into the funnels I I.

Patent Horse-Hoe.

" Fig. 2. (see the plate) represents the shafts, the axis and wheels, the coulters-beam, with handles, &c. as in fig. 1. being part of the said machine, and is convertible into a horse-hoe with six shares, by taking away the seed-box E E, the cylinder H H, the funnels I I, and the coulters K K, as in fig. 1. and introducing the hoes A A A A A A, fig. 2. in the places of the coulters.

" B, a guide projecting from the hoe-beam, which is useful in influencing the direction of the hoes, so as to avoid cutting up the rows of corn.

Hand-Hoe.

" A, fig. 3. the hoe plate of different sizes for drills at different distances.

" B, the wings for earthing up the soil to the rows of corn which may be taken off occasionally.

" C, the handle.

" D, a wedge, applied to the upper or under side of the handle C, so as to raise or drop the same to the height of the person who is to use it.

" Fig. 4. a rake, which may be applied to the handles of the machine instead of the coulters-beam, and may be used for making hay, clearing land from quitch, scarifying young crops of wheat, and other purposes.

Directions for using the Machine.

" The process of drilling should never be attempted but when the soil is dry, at least so dry as not to stick like daub to one's feet in walking over it, unless to regain a late, or in other respects a lost fertility.

" If the soil abounds with large dry clods, they should be reduced by a heavy roller ; and sometimes a spiked roller is necessary for that purpose. Previous to land being drilled, it should be ploughed deep, and harrowed slightly, to level the surface.

" Fig. 1. (see the plate) represents a back view of the machine, when put together for working.

" When the horse is put in the shafts, care should be taken that the chains or tugs by which he draws are of equal lengths ; otherwise the machine will have a constant tendency to deviate from the horse's line of traction. But when the horse goes in the furrow, the near side may be somewhat shorter ; and a chain may be extended from the end of the cross-bar to a part of the shaft near the horse's shoulder.

" In going from the farm to the field, or returning from the field to the farm, the pin or guide M must be lifted on to the hook L, which will bear the coulters off the ground.

And when going on rough roads, if the coulters-beam C C and the axis of the wheels are lashed together by a rope or chain, it will prevent the coulters receiving any injury, by coming suddenly to the ground.

" The grain or seed must be put in the upper boxes E E, an equal quantity in each box.

" The cups or ladles upon the cylinders, are of four different sizes, and are distinguished by the numbers 1. 2. 3. 4.

" No. 1. the smallest size (painted white) for lucerne, clover, cole, rape, &c. and will sow two pounds per acre. Also for turnip, and will sow one pound per acre ; every other cup being stopped up with a little soft clay.

" No. 2. (painted red) for wheat.

" No. 3. (painted green) for barley.

" No. 4. (painted yellow) for beans, oats, pease, tares, &c.

" By raising or lowering the slides G G, fig. 1. a greater or less quantity of grain or seed may be sown at pleasure.

" When the slides G G are as low as they can be, the wheat cups painted red, will sow something more than three pecks of wheat per acre ; and more in proportion the higher they are raised, not exceeding one bushel and a half, when raised as high as they can be, in rows at nine inches apart.

" The cups painted green, when the slides are as low as they can be, will sow one bushel of barley per acre ; and more in proportion as the slides are raised, not exceeding two bushels, in rows at nine inches apart.

" The cups painted yellow, when the slides are as low as they can be, will sow almost two bushels of beans, oats, pease, &c. per acre ; and more in proportion as they are raised.

" Upon soils well cultivated it is recommended not to sow more than one bushel of wheat per acre.

" Barley, from one bushel to a bushel and half per acre.

" Beans, from two, to two bushels and half per acre.

" Pease, two bushels per acre.

" Oats, two bushels and half per acre.

" Tares, two bushels and half per acre.

" The idea of over-stocking the drills with seed, is very absurd. The crops will be materially injured by so doing.

" It is recommended to make experiments upon different soils, by sowing different quantities of seed, in order to ascertain the most approved quantity per acre.

" If land is in a high state of cultivation, it is hardly possible to sow too little seed, provided the distribution is regular.

" The funnels I I, fig. 1. are all numbered, 1. 2. 3. 4. 5. 6. and for drilling at nine inches, must be applied to their respective places, so as to correspond with the number 1. 2. 3. 4. 5. 6. of the seed-box ; six coulters being fixed in the coulters-beam, at the distance of nine inches from each other.

" For drilling at twelve inches apart, five coulters must be fixed in the beam, at eleven inches and quarter from each other, when the order of the funnels will stand 1. 4. 5. 2. 3. 6. and no seed put in the box opposite the funnel No. 5. when placed as above ; the waste funnel may be stopped with paper to receive any seed that may accidentally fall therein.

" For drilling at eighteen inches apart, three coulters must be fixed in the left end of the beam at eighteen inches from each other, when the order of the funnels will stand 1. 2. 3. 4. 5. 6. and seed put in the boxes opposite the funnels 1. 3. 5. only the other boxes being empty.

" For drilling at twenty-two inches, three coulters must be fixed in the beam, one at each end, and one in the middle, when the order of the funnels will stand 1. 4. 5. 2. 3. 6. Seed being put in the boxes, opposite the funnels 1. 5. 6. only, the other boxes being empty.

" Two rows of pease at nine or twelve inches apart, and a space of twenty-two inches alternately, has been tried and approved.

" In level lands, without ridge and furrow, if the attendant on the machine cannot find a straight side to begin at, he should mark out with sticks or bushes a straight line, along one side of the field, for his direction ; and when drilling at nine inches, in order to make the space between the two adjoining drills, as he returns, equal to the rest, the wheel of the machine must be brought very near the last impression of the coulters, and three inches more distant from the last impression of the coulters, when drilling at twelve inches. And of other distances accordingly.

"As the machine approaches the land intended to be drilled, the lever P, fig. 1. should be lifted from the notch in the staple Q, when the coulters are two feet on this side the exact place where seed should be deposited; and the pin M removed from the hook L, by lifting up the handles D D.

"When the machine arrives at the end of the land, the lever P must be moved to the notch Q, which will stop in an instant the distribution of the seed, and the pin M lifted on the hook L, which will support the coulters out of the ground, while the machine is turning round.

"If the coulters should not make the incisions or drills something more than two inches deep in light sands or loams, and not quite two inches deep (one and a half is recommended) in strong clays or wet soils, they may be forced into the ground by the hand; or by weights, or a beam of wood four feet long and three or four inches thick, being suspended by chains or cords at the hooks T T in the handles of the machine for that purpose.

"If in attempting to make the drills straight, the horse should deviate from his proper direction, the coulters with all the coulters will be readily moved, this way or that way at pleasure, so as to make the drills straight by counteracting the irregularity of the horse's line of traction.

"If the machine should happen to be too wide for any given ridge, one or more funnels may be stopped with a little loose paper, and the seed received into such funnel, returned into the upper seed-box.

"In drilling narrow high-ridged lands, the outside coulters may be lowered, and the middle ones raised, so that the points of the coulters may form the same curve which the ridge forms.

"The top of the seed-box when shut, should be kept horizontally level, whether going up or down steep hills or on level ground. This will make the distribution of the seed uniformly the same. The higher the front edge of the box is raised upon the bar R, the seed will descend more copiously into the lower boxes, consequently a greater quantity will be distributed.

"It is apprehended, that if the driver of the machine was to sit on the seed-box, and drive with reins, he might conduct the machine much straighter than by leading the horse.

"The lower funnels placed behind the coulters should be lashed fast to the coulters with leathern thongs, or cords: and if in lifting up the coulters at the ends of lands, the upper funnels should, by chance, be displaced, a small nail may be driven into the edge of the seed-box, close above the edge of each funnel, which will prevent the funnels being displaced.

"If weeds accumulate upon the coulters, they must be displaced by a paddle; if land is dry, weeds will not be very troublesome; but if wet and clammy, and full of quitch, it will be troublesome, and, more or less, prevent the seed being distributed regularly in the drills. Such lands had better be made a fallow of, in order to clear them from weeds, than drilled with any corn whatever. This would be productive of great profit to the cultivator, and more credit to the drill system at large.

"When a piece of land is drilled, it must be harrowed once in a place, with common light harrows, to cover the seed, and level the surface of the soil, as a preparative for horse-hoeing. If the harrows are taken in the direction the drills are made, there will be no danger of displacing the seed.

"Seed wheat should be limed and brined two or three days before it is used, and made dry by spreading it thin on a boarded floor, to prevent its heating, so as to kill the seed: if seed wheat is fresh limed and brined, the lime, by acting as a cement, may cause it to clog in the cups. If this should happen upon the field, in hazy foggy weather, so much unlimed wheat as will make it separate, may be mixed therewith.

"Wheat should not, on any account whatever, be deposited more than two inches deep (one inch and a half is recommended) in strong clays or wet soils, nor less than two inches deep in all dry soils. The most approved depth is readily ascertained in soils of different textures, only by observing at what depth under the surface of the soil the secondary or coronal fibres of plants are formed in the spring.

"Lands formed into level ridges, four feet six inches wide, exclusive of the furrows, in strong retentive clays and

wet soils, and nine feet six inches wide, exclusive of the furrows, in all dry soils, are best calculated for the practical purpose of drilling, &c. in which case the horse will always go in the furrow, without setting a foot upon the land.

"Land intended to be drilled with carrot-feed should be deep ploughed; and for every half acre of land, one bushel of saw-dust and one pound of carrot-feed should be provided.

"The saw-dust must be well dried and sifted, to take out all the lumps and chips, and divided into eight equal parts or heaps. The carrot-feed must likewise be well dried, but not so as to kill the seed, and rubbed between the hands, to take off the beards, that it may more readily separate; and being also divided into eight equal parts, one of the above parts of saw-dust, and a part of carrot-feed, must be well mixed and incorporated together, and so on with all the respective portions of saw-dust and carrot-feed, till they are well mixed and incorporated together; which state, in the saw-dust with carrot-feed intermixed, may be drilled with the cups or ladles, No. 2. already described. Carrot-feed resembling saw-dust very much in size, roughness, weight, adhesion, &c. being well mixed with saw-dust, will remain so mixed during the sowing. One of the cups, No. 2. filled with saw-dust, will, upon an average, contain three or four carrot-seeds, by which means carrot-feed will be as regularly distributed in the drills as any other grain or seed whatever.

"If the wind should be high, when carrot or any other seeds are sown, it may be necessary to fix a screen of mat or canvass before the seed-box, to keep off the wind. By this, and the two side wings, S S, fig. 1. the seed will be perfectly screened from wind or rain.

Directions for using the Horse-Hoe.

"As the construction of this instrument (see the Plate, fig. 2) cannot well be misunderstood, a further description of it is thought necessary.

"For horse-hoeing a crop of any kind of corn, drilled at nine inches apart, the horse must be conducted along the third row or drill, beginning to number the rows, from the left-hand side of the six rows drilled at one operation of the machine. And the person who attends the hoes, must keep the pin B, fig. 2. directly over the third row of corn, and so long as he does this, it will be impossible for him to injure it in the least.

"For horse-hoeing corn at twelve inches apart, the horse must be conducted along the second space, between the rows or drills, beginning to number the spaces from the left-hand side of the five rows, drilled at one operation of the machine.—And the person who attends the hoes, must keep the pin B, fig. 2. directly over the middle of the second space, described as above: the same rule will hold good for hoeing at different distances.

"Where the space between the two adjoining outside drills shall happen to be irregular (i. e.) too narrow at some places for the hoe to pass, it may be advisable to take out the share, which would otherwise hoe that space, and leave it to be hoed by hand.

"Soils of different textures, will require to be hoed with shares of different sizes; nothing but experience can point out the size, which is best adapted to any particular soil. In all light sandy soils or loams, or any other soils sufficiently pulverized, shares from five to six inches broad, for nine inch drills, and eight inches broad for twelve inch drills, will work safely and effectually. In strong clays intermixed with pebbles, the hoe shares must not be so broad; and it may not be impossible to find some such soils as will bid defiance to all flat hoeing whatever. If, nevertheless, the texture of the soil in the spaces of the rows of corn, is tore to pieces by long narrow plates of iron, resembling points or chisels, being introduced in the hoe-share shanks, A A A A A A, fig. 2. instead of the hoe plates, the advantages resulting from such a process will be very considerable.

"The hoe plates or shares, may be set to enter the soil deeper or shallower, by lowering or raising the shanks A A A A A A, in the respective mortices in the beam, or by lowering or raising the hooks applied to the shank C C, on the axis of the wheels, by which the hoes are drawn.

"Lands cannot be too level on the surface, for practical, effectual, and expeditious horse-hoeing. But where lands, or ridges, are formed so round, that all the hoe plates cannot be

be brought to work at equal depths in the soil at the same time, so many as cannot be brought into use may be laid aside.

"As this method of horse-hoeing is perfectly new, it is recommended to take the horse-hoe with the machine coulters fixed in the hoe beam, instead of the hoe shares, over several acres of drilled corn; by which means, the person who is to attend the horse-hoes, will, by seeking the coulters in the middle of the spaces, become familiarized to the method of influencing the direction of the hoes, so as to avoid cutting up any of the rows of corn.

"This horse-hoe may be applied to many useful purposes, besides hoeing crops of drilled corn, particularly for cutting up the rows of stubble as soon as the crop is carried with such weeds as might escape the hoe; and for stirring of fallows; &c. &c. after the rate of ten acres a day, with one man, a boy, and two horses, particularly in the busy time of harvest, when it would be impossible to spare so many men and horses as would be required to stir the land with common ploughs, so as to answer the intended purpose. And by means of the same expeditious method of cutting up stubbles (in Kent called *shimming* or *spuddling*), immediately after the crop is carried, or rather before it is carried, as soon as it is cut and set up, in order to gain time for the sowing of grass seeds a second time, where they may have missed, or cole, or rape, or turnip, for food of sheep or cattle, in winter or spring, extraordinary advantages may be derived."

One great benefit of hoeing is, that it keeps plants moist in dry weather, the advantage of which to their growth is easily seen. This good office it performs on a double account. First, as they are better nourished by hoeing, they require less moisture, and consequently carry off less; for those plants which receive the greatest increase, having most terrestrial nourishment, carry off the least water, in proportion to their augment, as is proved by Woodward's experiments. Thus barley or oats being sown on a piece of ground, well divided by tillage and dung, will come up and grow well without rains, when the same grains sown on another part of the same land, not thus dunged or tilled, will scarce come up at all without rain; or if they do, will wait wholly for the rains for their growth and increase.

The hoe, also, particularly the horse-hoe, for the other does not go deep enough, procures moisture for the roots from the dews which fall most in dry weather; and these dews seem to be the most enriching of all moisture, as it contains in it a fine black earth, which will subside from it in standing, and which seems fine enough to be the proper pabulum, or food for plants.

A demonstration that the tilled earth receives an advantage from these dews, which the untilled does not, is this; dig a hole in any piece of land, of such a depth as the plough usually goes to; fill this with powdered earth, and, after a day or two, examine the place, and the bottom part of this earth, and the bottom of the hole, will be found moist, while all the rest of the ground, at the same depth, is dry. Or, if a field be tilled in lands, and one land be made fine by frequent deep ploughings, while another is left rough by insufficient tillage, and the whole field be then ploughed across in dry weather, which has continued long, every fine land will be turned up moist, and every rough land as dry as powder from top to bottom.

Although hard ground, when thoroughly soaked with rain, will continue wet longer than fine tilled land adjoining to it, yet this water serves rather to chill than to nourish the plants standing in it, and to keep out the other benefits of the atmosphere; it leaves the ground much harder also than before, when it is finally exhaled out of it: and when, at length, the earth is then hardened, it can receive no benefit from any thing less than a deluge of rain, which seldom falls till the season of vegetation is over.

As fine hoed ground is not so long soaked with rain, so the dews never suffer it to become perfectly dry. This appears from the flourishing state of plants in hoed ground, while others near them, but in ground not hoed, are starved for want of nourishment. The common opinion is against this, but observation proves it to be true against the common opinion. The vulgar are guided by this, however, and will not hoe their ground in dry weather, for fear of letting in the drought, as they call it; whereas hoeing this, is the only method of keeping away the drought, and without either this, or watering, they must perish in these seasons. *Tull's Horse-Hoeing Husbandry.*

Mr. Marshall, in his *Rural Economy of the Midland Counties*, says "This year (1784) I have given eight shil-

lings an acre; with beer; for hoeing turnips; and, even at this price, it has been with difficulty I have got them tolerably done.

"The price, compared with that of Norfolk; is extravagantly high. But there are two reasons for this disparity.

"In Norfolk, every plowman and every harrow boy is a turnip hoer: here, hoeing is a mystery, practised only by a few, who have it in their power to make their own terms.

"Beside, in Norfolk, the soil is light, and free from stones: the hoe passes freely through it, and the hoer, sweeping his tool round the plants at pleasure, works from hour to hour without a check. But here, the soil, in most places, abounds with pebbles, and, being of a more stubborn and cloddy nature than the sands of Norfolk, the hoer is frequently under the necessity of chopping three or four times, perhaps, in the same space of surface which a Norfolk hoer would clear with one sweep of his hoe. Were he to attempt to *draw* his hoe in the Norfolk manner (perhaps not the best), he would be liable (by reason of the obstructions turning aside his hoe from the intended direction) to cut up the plants he meant to set out, and to smother those he had already singled. Beside, he cannot, here, use so wide a hoe, as is used in Norfolk.

"The Midland hoers generally use three-cornered hoes; each side about seven inches. The reasons given for using these hoes, in preference to those of the usual one-edged form, are, that they require to be carried seldom to the grinding stone, and that they are handier to single a plant with, than a one-edged hoe. It is allowed however, that a three-sided hoe requires more labour than a single one; whose blade, forming a more acute angle with the handle, lies flatter, and passes more freely through the soil than the triangular ones; which standing nearly at right angles to the handle, are drawn against the soil rather than under it; and, while that cuts off the weeds clean, these have them to pull asunder: beside, where the soil is sufficiently loose to admit the hoe to be drawn, they are very mischievous, in burying the singled plants.

"To obviate these evils, as much as may be, the handles are made short; about three feet long; the workmen stooping, proportionably, in using them. If they were more dishd, (they are a little), the mould would lodge in the hollow, and make them still more clumsy.

"Among stones and clods, the triangular hoe has its merit; acting the part of the West India hoe, or a mattock. But, where the surface is tolerably free and friable, the one-edged hoe, from seven to eight inches wide, and about two and a half inches deep, is a more eligible tool."

HOG, the name of an animal too well known to need any description here.

These creatures are very advantageous to the countryman not only for their great increase, but also because they feed upon what would otherwise be of no use or advantage, but would be thrown away; as whey, washings of tubs, grounds of drinks, dish-water, grains, &c. and their flesh being best salted, or kept in pickle, may be eat in the spring, when other meat is at the dearest; besides the help it affords to the taking off the produce of the garden, and the variety of the dishes of the offal. Swine are indeed very greedy, and very apt to root up ground, and break the fences; and therefore the greater care must be taken to keep them both well ringed and well yoked.

The largest swine, and the greatest number for any particular places, are bred in Leicestershire, and Northamptonshire, and in the clayey countries adjacent: probably from the large quantities of beans and pease sown in those parts.

The wild kind are not so large as those just mentioned, but are much more hardy, and better meat.

In the choice of hogs, chuse such to breed out of as have long, large bodies, are deep sided and bellied, that have a short nose, thick thighs, short legs, high claws, thick neck, a short strong groin, and a thick chine, well set with strong bristles.

Mr. Marshall, in his *Minutes of Agriculture* says he found by experience that the large, long haired, dark-spotted, domestic English breed, much the most eligible; because it is the hardiest and the most tractable.

To have too many sows in one yard is not good, for their increase is so great, that they will, for want of food, not only devour whatever comes in their way, but eat one another: for a sow will bring forth pigs three times a year, that is, at the end of every sixteen weeks. It is common for them to have thirteen or fourteen pigs at a litter; but the

the sow can rear no more than she has teats to suckle them with; the rest must therefore be destroyed, or put to other sows. If the sow miss the time of going to boar, that she might in course have done, give her some oats parched in a pan, in her wash, or the small end of a runnet bag, and it will cause her quickly to go to boar. The pigs which you rear, after you have chosen out the best for boars and sows, the males must be gelt, and the sows spayed: the spayed gels, as the farmers call them, are esteemed the most profitable, because they have a much larger quantity of fat upon their inwards, than other hogs. Young shoats, which are swine of about three quarters of a year old, are best for pork, and those of a year, or a year and a half, for bacon. The best age for a sow to bring forth pigs, is from one to seven years old, and the best age for the boar, is from two to five years old, at which time it is best to geld him, or sell him for brawn; the best pigs to rear are those which are pigged in the spring, and those pigged in March, for pork in October.

The best way of taking care of swine, is to feed them so as to keep them in middling plight, till you design to fat them; for if you keep them too fat, it will endanger their health; and too lean will render them too ravenous. It is good to give them such swill as you have, every morning and evening, to make them come home to their styes. The rest of the day, let them graze, and get such food as they can; but when the corn is upon the ground, you must be careful to keep them within bounds. Moist sedgey grounds are good for them, the roots of which they will eat; and all sorts of haws, heps, sloes, crabs, acorns, mast, chestnuts, &c. with which, if you have plenty enough to fat them, the flesh will eat much better and sweeter than if fattened in a sty. Some, indeed, say their fat will not be so solid, nor so profitable, and therefore they commonly shut them up for a week or ten days, and feed them with dry peas; but this is a mistake, experience having shown, that hogs fattened with acorns only, have their fat as solid as those fattened with peas. In fattening hogs in styes, they observe to give them meat often, and but little at a time, that it may be always fresh; and likewise to give them as much water as they will drink, and to keep them very clean, which will help their fattening, and improve the taste of their flesh. But where the husbandman lives remote from woods, or the year should fail of producing acorns or masts, they commonly fat them wholly in styes with peas, if cheap; if dear, the meal of barley, rye, or offal corn, according as they are cheapest, which they mix with water, whey, or skimmed milk: with these they feed them till fat, which will commonly be in about a month's time, and then they feed them with peas a little before they kill them.

Observe, that every sty have a yard well paved with stone, if possible, for the hog to go out and ease and air himself, that he may keep his lodging the cleaner.

In Leicestershire they have a very easy method of fattening great numbers of swine, which they do by stacking up their peas and beans in the form of a small cottage. This they set near some running brook, and hedge a yard in round about it; taking some part of the stream into the yard for the hogs to drink at: into this yard they turn such a number of hogs as they think their peas or beans will fat, where they let them live till their provision is consumed, cutting the rick down, and giving it to them as can eat it. *Mortimer's Husbandry, vol. 1. p. 244.*

The London Society of Arts having, some time since, offered a premium of 20l. or a gold medal for the best account of rearing and fattening of hogs, in consequence of which Mr. Young sent them a series of trials, as a candidate for their medal, and was honoured with it.—The following particulars are extracted from his Essay.

"The importance of this animal to the farmer is not sufficiently known in every part of England; there are many dairies that do not maintain one tenth of the swine they might, with proper management. Several garden-roots are raised in large quantities, without being applied to feeding hogs; and clover is cultivated, in many countries, upon the largest scale, without its utility for the same use being the least known. No person who has tried many experiments in this part of rural economy, can fail regretting, that so many farmers should neglect a conduct that adds so much to the good of the public, as well as to their own profit.

"There are two principal objects in the rearing and fattening hogs; first, to make the greatest advantage of a

dairy; and secondly, to substitute some other food, in the place of that which arises from cows, where none are kept.

"It is the practice of several counties to use the skim-milk, butter-milk, and cheese-whey, in fattening hogs. This is a most pernicious custom; that food, for such a use, it is every where known, has twenty substitutes, viz. peas, beans, buck-wheat, barley, &c. &c. but it is not so generally known that pigs may be reared without cows. It is agreed that the dairy food is excellent for the latter purpose.

"For this reason, I shall venture to propose a different conduct, and with the greater readiness, as I have found it, by experience, to be more profitable than the common management. The dairy upon this improved system should be applied only to rearing pigs, and feeding sows which have young. But this at once opens a larger prospect of the whole management of a farm.

"The sows and weaned pigs should evidently be proportioned in such a manner to the number of cows in milk, as to consume all the dairy food without waste. And other sorts of food provided for the keeping sows that have no pigs; hogs half, three fourths, full grown, and fattening ones.

"The practice of some counties, as well as the annexed experiments, prove that clover is a most capital object in keeping all these sorts of swine; but those writers who assert that it will completely fatten them, go much too far. There is no sort of cattle in a farm that requires more attention than hogs; any method, therefore, that simplifies the management must be peculiarly valuable.

"Hogs that are a quarter (or upwards) grown, may be absolutely confined to a clover field, until it is necessary to sow wheat. Nine tenths of Britain will doubt this fact, but I have frequently experienced the truth of it. The fences, it is unnecessary to add, must, in this system, be incomparably good; which necessity, I apprehend, is a particular merit in a mode of husbandry: for a conduct that forces the farmer to have excellent fences, is so far of great utility. It is also requisite to add, that there must be a pond in the field which never fails. In a good crop of clover, well fenced and watered, swine of this sort may be locked up from the middle of May to Michaelmas, and no consumption of the clover will pay the farmer better. I shall add an experiment or two to prove this assertion. I could insert many, but a certain brevity is requisite in such slight essays as these. I have found lucerne to be equal, and in some years superior to clover for this use. Sainfoine is also of excellent utility, but ray-grass and burnet will not by any means do; natural pastures with wash are a good substitute, but never will be found to equal the artificial grasses.

Experiment of keeping Hogs upon Clover in the Field.

"Sowed common red clover with barley in the spring in 1765, on two acres of woodcock, brick-earth loam, on a clay bottom, that yielded beans, horse-hoed, in 1764. In October, 1765, manured it with thirty loads of compost, consisting of various proportions of farm-yard dung, town manure, turf, ditch-earth, &c.

"The fences around it were well repaired in the winter, and one, much worse than the rest, new made.—The 12th of May I turned in thirty head of swine, consisting of sows, large pigs, and large half and three fourths grown; they took immediately to the clover, and in about a fortnight, all discovered by their looks, how well the food agreed with them. There was a pond in the field, at which they drank perpetually; and of nights they laid all of a heap, in a corner of the piece, under a thicket of bushes, not making any attempts to get home, after walking the first evening once or twice around the border with that design. Finding that stock of hogs were insufficient to keep down the clover, more were added, and some kept in the piece till Michaelmas. The account of the expence and produce is as follows.

EXPENCE.

Expences	5	4	7
Profit 2l. 7s. 9 $\frac{1}{2}$ per acre	4	15	7

"From the event of several other fields of clover this year, I am clear that no other use of it would have paid better than thus feeding it by hogs. A clear profit of forty-seven shillings per acre, after paying the expence of a good manuring, is considerable, and greatly preferable to the general profit by hay, the chance of the seasons taken into the account. Nothing can be clearer than the fact of hogs thriving excellently on clover. All these swine grew very fast, and shewed by their looks how well the food agreed with them, and there is no animal that sooner falls off in his appearance than a hog, when badly fed. Where therefore is the necessity of providing other summer food? Why consume that food for those hogs which clover will maintain, while sows and pigs, and weaned pigs cannot be kept without it, such as dairy wash, &c.

"This is a system of management that will enable the farmer to keep much larger stocks of cattle, than the methods yet common in so many counties."

A profit of 2l. 7s. 9d. $\frac{1}{2}$ per acre, is, no doubt, inviting to a farmer, to keep his hogs in summer upon clover: there is however another circumstance that he should consider in his management, which Mr. Young has not taken notice of, but deserves consideration.

The intention of sowing clover among spring corn, as oats and barley, is to obtain good crops of hay, and to prepare the land for wheat: for all succulent plants that stand thick upon land, so as to shade and cover it, are found to enrich it, as pease, buck-wheat, vetches, turnips, and clover. Most farmers are now sensible of this; it is an article of modern improvement, of great importance to them and the public. It is generally allowed that a full crop of clove prepares land for wheat almost equal to a fallow, and some think superior.

The clover is fed off by cattle, or mowed: sometimes it is mowed once, and afterwards fed, or it is mowed twice, and not fed. Which ever of these methods is pursued the land is improved: but as mowing of meadows often is known to impoverish them, it was long supposed that mowing clover had the same effect of impoverishing land, more than feeding it; but this is now found to be a mistake: land is more enriched by clover, though twice mowed, than by feeding it all the summer, as has been found in the succeeding crop of wheat, by comparative experiments of both. The reason of this, and of the fertilizing effect of shade and cover, not being our present enquiry, let us proceed to the point now before us, the benefit of feeding clover with hogs. A method which will be more or less advantageous to the farmer, in proportion to the effect of it upon the succeeding crop of wheat, and this the farmer may judge of by the condition of his land, and the luxuriance of the crop of clover. The wheat crop is his first object when that is intended to succeed, and the improvement of that is to be considered in the management of his clover, whether by mowing or feeding it.

"But in making the greatest advantage of a dairy," continues Mr. Young, "we must not confine ourselves to the summer-keeping alone; provision must be made for winter-feeding such hogs as do not require assistance from the dairy. The following experiments will prove that carrots, parsnips, beets, and potatoes, are of admirable use in feeding pigs that have been reared. They will keep the hogs that are taken care of the clover in excellent order, and even fatten them, and maintain to vast advantage, sows that have no pigs.

"By this general system of management, it appears, that hogs are to be maintained the year through upon clover and these roots, and recourse had to the dairy only for assistance in feeding sows that have pigs, and in rearing their young. It must be extremely evident, that, with this conduct, the number of swine maintained on a dairy farm

may be prodigious. The number of cows point out the number of sows and pigs, and these again must proportion the number of acres applied to the production of clover and roots. Thus the whole chain of crops is connected, and each field the support of the other.

"The second object in the management of swine, is the substituting some food in the room of a dairy for rearing pigs, upon such farms as keep no cows. This is an object of very great importance, as there are numerous extensive tracts of country that will produce clover in very great perfection, and also many sorts of roots; but where it is either unprofitable to keep cows, or only advantageous to suckle them.

"The reason I before gave, viz. keeping this sketch in due bounds, prevents the insertion of numerous experiments, which I formed for the particular determination of this point. I found, from repeated trials, that carrots and parsnips will wean pigs of a proper age almost as well as milk; that is, in such a degree of perfection as to render the keeping a large number of hogs upon that dependence, extremely advisable to any farmer, whose business or situation may prompt him to do it. And other experiments assured me, that sows, with the most numerous litters, may be maintained to great profit in the same manner. Potatoes and red beets I likewise found of very great use for the same purpose.

"It may not be improper here to consider the consequences of enabling the farmer to keep large stocks of swine by means of roots, so extremely productive as those I have mentioned. There are no soils but what, with proper management, will yield some or other of them, and the crops are immense. The number of swine to be fattened or fed by an acre of carrots or potatoes would surprise those who have never formed any experiment upon the point; and the excellency of the husbandry, in general, should plead powerfully with our farmers to adopt it upon this principle. These roots are all fallow-crops, that is, they are of the same advantage to the soils as a year of fallow, and, if cultivated in the manner they ought to be, much superior to any fallow: for this reason, their culture is beneficial to the land, and a very material method of bringing it into excellent heart. Their application to feeding swine is alone sufficient to improve a farm that is almost worn out, since it cannot be conducted without raising large quantities of the very best dung.

"Here the consequence of adopting the culture of vegetables that clean and ameliorate the soil, and in their use infinitely enrich it, must be obvious to every reader. It is no exaggeration to assert, that the best soils may be improved, and the poorest converted into good ones by this conduct, and I can assert, on experiment, cheaper than by any other method. I have found that ninety hogs will in fattening, yield as much manure as was worth thirty pounds on the spot, and where straw, stubble, or fern are to be had very cheap, to a much greater amount.

"It is from these several considerations that I apprehend the following experiments may be of real utility to those who have dairies, to those who keep cows, but apply them to suckling, to those who have no cows, but are willing to keep swine; and lastly, to those who, on any soils, are desirous of improving them."

Mr. Young then proceeds to relate several experiments he made of feeding and fattening hogs with different sorts of food, whereof the following is a specimen:

Experiment on feeding Hogs.

Exp. I. The first week in March, 1765, thirty pigs, just weaned, were drawn from forty-three, that they might be all of a size; they were then distributed into five lots, equally divided. I do not think there was half a crown difference in the value of them, and then fed with distinct sorts of meat. Each five had a sty to themselves, and all were kept clean and littered with straw.

- Lot. No. 1. was fed with pollard mixed with water.
 2. with pollard mixed with skim-milk.
 3. with boiled turnips, and pollard mixed with the turnip liquor.
 4. with-boiled potatoes and water.
 5 with skim-milk.

They were kept with this food thirty days. I then turned them out of their styes, (none had died) and view-

ed them with a person particularly skilled in hogs ; the result was,

- No. 2. the best—pollard and skim-milk.
5. the next best—skim-milk.
1. next—pollard and water.
3. and 4 equal.

It appears from hence that pollard and milk are the best food, milk alone very good. The other articles advantageous (for none of the pigs were in bad order), though not equal to the former:

Exp. III. January 1, 1766, forty pigs, that had been weaned about a fortnight, were draughted very equally into eight lots, and confined each to a sty, they were cleaned out and littered on the same day, and equally. Their food was as follows :

- No. 1. Raw carrots.
2. Boiled ditto.
3. Boiled potatoes.
4. Pollard mixed with skim-milk.
5. Pollard mixed with boiled turnips.
6. Malt dust mixed with skim-milk.
7. Skim-milk.
8. Ditto and half carrot-water boiled.

" They continued upon this food the month of January, and were then viewed, the result was as follows :

- No. 4. the best—pollard and milk.
 7. next—skim-milk.
 2. ditto—boiled carrots.
 3. ditto—boiled potatoes.
 5. ditto—pollard and boiled turnips.
 8. ditto—skim-milk and carrot-water.
 1. ditto—raw carrots.
 6. the worst—malt-dust and skim-milk.
- Two dead.

Pollard and milk hitherto maintain the superiority, boiled carrots excellent, the rest almost equal, except the malt-dust, which is evidently bad.

Exp. IV. " In the beginning of June, 1766, I confined sixty hogs, half and three fourths grown, in my hog-yard (a pond's mouth in it), and fed them fourteen days with clover, mown fresh every day ; it was given in their troughs, with racks across to prevent the soiling it. They fell off in their looks in about four days, and grew worse and worse, several dying. At the end of that time, I gave them some malt, grains, and wash every day for a few days longer, but the effect was no better, more dying. They were then all turned into the clover field whence it had been taken, and confined constantly to it for some time. Not one more died, for all thrive greatly. It will not perhaps be impertinent here to add, that I never found any method of using clover more beneficial than thus applying it to the feeding of hogs."

Exp. V. " At the time of the preceding experiment, eight hogs, of equal size, were divided into two lots, and confined to two styes. Four were fed fourteen days on clover mown, and the other four on lucerne mown ; they were given at the same time, and in the same styes. At the end of that time the same were viewed attentively : both were bad, the clover ones much the worst, one near dying."

Exp. VI. " In the month of December, 1766, twenty pigs, that had been weaned a month, were draughted into four parcels, and kept that month separately, in the following manner :

- No. 1. Boiled carrots.
2. Boiled potatoes.
3. Boiled turnips.
4. Boiled cabbages.

" At the end of the month they were turned out and viewed attentively. The result was,

- No. 1. the best—boiled carrots.

2. next—boiled potatoes.
- 3 and 4 equal—all nearly dead.

" Carrots continue, in every trial, superior to all common vegetable food. I am not at all surpris'd at the ill success of turnips and cabbages.

Exp. VII. " In June, 1767, I draughted from my hogs twenty that were of a perfect equality in size and appearance ; they were even half grown ; marked them into four lots, and turned,

- No. 1. into my clover field.
2. lucerne ditto.
3. sainfoine ditto.
4. burnet ditto.

" In another month they were drove up and viewed ; the result was,

- No. 2. the finest—lucerne.
1. next—clover.
3. next—sainfoine.
4. very indifferent—burnet.

" The result of this experiment I think decisive in favour of lucerne, and likewise in the proportionable merit of the other articles : but this must be farther enquired into in future experiments."

OBSERVATIONS.

The general result of those trials is drawn into one view, in a very few words.

Milk mixed with pollard appears to be, of all food, the most proper for rearing pigs.

Milked alone is good.

Boiled carrots excellent, and fully proved to be sufficient for any farmer to depend on who does not keep a good dairy.

Potatoes, boiled to a batter, also a very good food.

Turnips, cabbages, and malt-dust very bad.

Of green food, that which is growing is clearly the best ; mown, and given in styes, it is pernicious.

In the field lucerne is superior to all the rest. Clover comes next, then sainfoine, all these three are good. Burnet last and bad.

The next set of experiments were made in order to discover what kind of food was most proper for fattening hogs, given to them separately, and the best mixtures of them for that purpose. The following example may be sufficient to show the comparative use of different kinds of food given separately for fattening.

Exp. II. " In January, 1766, I drew from the herd ten hogs, as equal in size as possible, and weighed them alive in five lots.

No.	weighed	stone	lb.
1.		13	4
2.		12	6
3.		13	0
4.		12	11
5.		13	1

A nearer equality than this, in matters that can neither be added to nor diminished, can scarcely be expected.

No. 1. was fatted with white pease, that weighed 56 lb. per bushel ; the price 30s. per quarter.

No. 2. with pollard that weighed 22 lb. per bushel ; price 9 d. per bushel.

No. 3. with buck wheat 47 lb. per bushel ; price 2s. 3d. per bushel.

No. 4. with boiled potatoes 54 lb. per bushel ; price 2 s. per bushel.

No. 5. with boiled carrots 55 lb. per bushel ; price 1s. 1d. per bushel.

" I thought it best to fix on a given sum, as proper to fat each hog. The people I consulted were of opinion that eight bushels of white pease were necessary to fat one such hog well. This I accordingly fixed on as my criterion. The account of the expence therefore stood thus :

No. 1.

No.	Food	Weight	l.	s.	d.
1.	Pease, 16 bushels		3	0	0
2.	Pollard, 80 bushels		3	0	0
3.	Buck wheat, 27 bushels		3	0	9
4.	Potatoes, 28 bushels at	2 16 0 }	3	0	0
	Labour and coals	0 4 0 }			
5.	Carrots, 49 bushels	2 13 2 }	3	0	0
	Labour and coals	0 6 10 }			

Each lot was weighed as soon as the food was done. The result was as follows:

No.	Weight	stone	lb.
1. weighed	27	6	
2.	27	9	
3.	29	13	
4.	25	7	
5.	31	0	

"It is evident from this experiment, that carrots boiled are superior to any other food. I did not expect that potatoes would be so much inferior; but I have found, from divers other trials since, that it is requisite to mix the meal of some kind of corn with them. Pollard in this trial, as in the last, is superior to pease."

With respect to the comparative fattening quality of carrots and potatoes, it appears by this experiment that lot No. 5. gained 17 stone 13 pound weight in flesh, fed upon carrots; and lot No. 4. fed upon potatoes, gained but 12 stone 10 pound. The difference was 5 stone and 3 pounds of flesh gained by feeding on carrots, more than was gained by their feeding on potatoes, a great superiority when viewed in this light. But on the other hand, to gain this greater weight there was a consumption of 49 bushels of carrots, and but 28 of potatoes. But 49 bushels of potatoes (the same quantity as the carrots) would, in the above proportion, advance such a lot of hogs to the weight of 22 stone and 4 pounds; that is, to 4 stone 5 pound more in weight, than the same quantity of carrots did advance them, by which it appear that potatoes are really more fattening than carrots, of the same measure or weight. The hogs seem to relish carrots much, and they eat a great quantity of them; but taking an equal quantity of each, the potatoes go farthest in fattening hogs, a circumstance that merits the farmer's attention; for it is much more difficult to find a soil that is proper for carrots than for potatoes, and the produce from an acre of potatoes is nearly as great, and frequently greater than the produce of carrots; nor is there much difference in the expence. This however is certain, that in most farms, there is much more land proper for potatoes than for carrots.

The price of the potatoes, in this instance, is indeed much higher than the carrots; but that is a circumstance merely local, it is not so in all places; as the farmers may, in general, raise potatoes as cheap as they can carrots, and in much greater quantities.

The other experiments, in this Essay, were made, in order to discover the fattening quality of several sorts of food, when mixed together; pollard, bran, and of beans, pease, buck-wheat, and barley ground into meal; upon which the author makes the following observations.

"It appears from these experiments, that pollard alone, at the preceding prices, is a cheaper food than pease alone.

"That boiled carrots is much the most profitable food that has been tried.

"That buck-wheat is a more profitable food than pease.

"That several kinds of food mixed are better than given alone.

"That the meal of any one, or various kinds of grain is better, and more profitable than the whole grain mixed or alone.

"That pease and barley are a much sweeter food than beans."

HOGS, *the Mange in*. Mr. Young, in his Annals of Agriculture, vol. XV. inserts the following account (by William Norford, M. D.)

"The mange in hogs, dogs, &c. is similar to the *pruritus*, or itch, in the human body; and is to be cured in nearly the same manner. It is a local disease, and arises from an insect, which works itself under the cuticle, or outward skin, and there causes so violent an itching, that the animal scratches and rubs itself to such a degree, as to tear off the top of the pustule, which occasions a scab, and in a little time an ulceration. In the microscope this insect appears like the weaver bred in stale oat-meal; and

is said to have a snout as well formed to work under the skin, as the hog has to root and turn up the outer surface of the earth.

"From this account of the disease, your own good sense will suggest to you, that no internal medicine is necessary to make a cure.

"The idea of giving drugs to drive out the mange, or itch, is as ridiculous as it would be to give medicines to drive out the larger insects; as lice, &c. with which animals are often infested. But if this distemper should be suffered to continue so long, that pretty large ulcerations are formed all over the animal, in that case the matter of these little sores will be taken into the blood or habit, and so may make an internal disorder; for which it may be proper to give something to restore the health of the animal, after the external disorder is removed. One principal cause, perhaps, of the mange, is filth and nastiness; but when I say this, I beg to be clearly understood, that I do not think the hog is more liable to it than dogs, and many other creatures, because he is said to delight to roll himself in dirt and mire; which is so far from giving him the mange, that I believe it often prevents it; the filth and nastiness I mean, is what comes immediately from the body of the animal itself, which, in some cases, is the worst of all poisons, and may occasion the plague, or what is called the murrain, in cattle. Where many hogs lie together for a length of time, and by the carelessness of the servant, or want of attention in the master, are suffered to continue in the same litter, or straw, till it is quite ground down into short stuff, like chaff, although it should be perfectly dry, it will breed minute insects, such as lice, &c. and, I make no doubt, the very animalcule which occasions the mange. Great care, therefore, is necessary to keep hogs, dogs, &c. perfectly clean, if you expect to preserve their health; and every corner and part of the sty and kennel should be swept clean before fresh straw is put in; and never suffer them to have a clean bed laid over the dirty one, as it is too frequently done, where the immediate eye of the master is wanted.

"The following is the ointment which I recommend for the mange in hogs or dogs; and I never knew it fail of making a perfect cure, when it was properly applied, and due care taken to keep the animals clean afterwards.

Take of hog's lard, three ounces; sulphur vivum, in very fine powder, one ounce; white hellebore, fresh powdered, two drams; water of kali, half an ounce.

"Mix these ingredients very well together, by rubbing them on a marble slab, with a proper knife. This quantity will be sufficient for a hog of six or seven stone, and the whole should be very well rubbed in at one time; and if this is properly done, there will seldom be occasion for a repetition of it. Hogs that have many ulcerations, from the mange being long neglected, will sometimes, after the mange is cured, have chops, or cracks, in several parts of the body, particularly about the neck. These cracks are best cured by anointing them with tar-ointment; a little of which should be rubbed into the chops, once in three or four days, till they are well. Instead of purging the hogs after the cure of the mange, if they should not seem to be perfectly well, that is to say, if they should have a slight cough, and their bellies be too large, supposing them to be fed with proper food, give each of the hogs, according to his size, from half an ounce, to an ounce and half, or two ounces, of crude antimony, well levigated in some of his food; and this should be continued for ten days or a fortnight. The antimony is a cheap drug, and will, for the most part, restore them to perfect health.

"The tar-ointment commonly sold in the shops is often made with hog's lard instead of fine mutton suet; by which means the softness of the lard so soon melts when applied to the grieved part, that it does not cover the diseased and weak fibres a sufficient time to heal them, as it actually does when made with mutton suet. I shall therefore give a receipt how to make it.

Tar Ointment.

Take of the best tar; mutton suet, prepared; of each an equal quantity.

"Melt them over a gentle fire, and strain the ointment, while the fire is hot. This is also an excellent ointment for

for cracked heels in horses, and always ought to be kept in the stable for that use.

HOG-CISTERN. Mr. Marshall, in his *Rural Economy of Norfolk*, Min. 13. says. "Hog-cisterns, in this country, are principally built with bricks and terrace. But this is expensive: yet a hog-cistern is among the first conveniences of a farm-house. Wooden vessels are incommodious, and leaden ones dangerous.

"This summer a receptacle for water in a brick-yard being wanted, I had one built of bricks, laid in clay, and surrounded with a coat of the same material: it holds water perfectly.

"Afterwards, I built a hog-cistern in the same manner. This morning, on enquiry, I find that not only the tenant, but his wife and her maids, are fully satisfied with it.

"It was built in this manner. A pit five feet and a half long, by four feet wide, and five feet deep, was sunk in the place most convenient to the dairy, kitchen, and hog-yard jointly.

"The bottom of the pit was bedded with some extraordinarily fine clay, fetched from the sea-coast for this purpose; moistened and rammed down; and its surface smoothed over with a trowel. On this flooring were laid three courses of bricks, in clay-mortar (the best of the clay being taken for this purpose), and in such a manner, that the joints of one course fell in the middle of the bricks of the course below; the whole being laid long-ways; not crossed, in the usual manner.

"The sides were carried up half a brick thick (that is, a brick in width) with mortar of fine clay; and, in a vacancy left between the brick-work and the sides of the pit, moist clay was firmly rammed; so as to unite as much as possible the bricks, the clay, and the sides of the pit into one solid mass; carrying the brick and clay work up together; and beating back such bricks, into the clay, as were forced forward by ramming.

"The cistern when brought up level with the surface of the ground measured three feet long, two and a half feet deep; consequently the surrounding seam of clay is not more than four inches thick; and the stratum at the bottom is about the same thickness.

"Above-ground, a nine-inch wall was raised on each side, two feet high, with a gable carried up at one end; and, on these, a span or pitched roof was set, and covered with tiles; the other end being left entirely open as a doorway.

"This is an admirable covering for a cistern. A flap (whether it lie horizontally or sloping) being continually exposed to the weather, lets in rain-water; soon rots; and, from the manner in which it hangs, is liable every day to be split, and its hinges forced off, by the heedlessness of servants: whereas a door, having only a gentle fall, and being always under cover, will last a number of years."

HOG-SHEEP, or *Hoggræh*, a sheep of a year old.

HOG-STY *rubbing post*. Mr. Marshall, in his *Minutes of Agriculture*, observes that "every sty should have a rubbing-post.

"Having occasion to shift two hogs out of a sty without one, into another with a post, accidentally put up to support the roof, I had a full opportunity of observing its use.

"The animals, when they went in, were dirty, with broken ragged coats, and with dull heavy countenances. In a few days, they cleared away their coats, cleaned their skins, and became sleeky haired; the enjoyments of the post were discernible even in their looks: in their liveliness and apparent contentment.

"It is not probable that any animal should thrive, while afflicted with pain or uneasiness.

"Graziers suffer single trees to grow, or put up dead posts, in the grounds, for their cattle to rub themselves against; yet it is probable, a rubbing post has never been placed, intentionally, in a sty: though, perhaps, for a twofold reason, rubbing is most requisite to swine."

HOLCUS, or *couchy soft-grass*, a vile weed which infests arable land; the leaves springing up as high as the wheat-stubble, and the soil full of its couchy-roots.

HOLT, a wood.

HOLM, an island in a river; it also signifies the holly.

HONEY-DEW, is frequently observable on the leaves of trees, which is followed by their being blighted, but the corn does not receive any obvious injury from it.

HOOF of a horse, is all the horn that appears when his foot is set to the ground; the hoof should be of a fi-

gure very near round, and not longish, especially towards the heel, for long feet are worth nothing.

The horn of the hoof should be solid, tough, high, smooth, without any circles, somewhat shining, and of a dark colour, for the white is commonly brittle, and may be known by many pieces being broke from the horn round the foot: to be excellent, the horn should be of the colour of a deer's hoof, and the whole foot round, but a little larger below than above.

The hoofs of a horse are either perfect or imperfect; the former, but now described, is so disposed, that the horse may tread more on the toe than the heel, being also upright, and somewhat hollow on the inside.

As for the imperfect hoof, it is that which wants any of the aforementioned qualities, particularly if it be not round, but broad, and spranding out on the sides and quarters; that horse for the most part has narrow heels, and in process of time, will be flat-hoofed, neither will he carry a shoe long, or travel far, but soon subside; and by treading more upon the heels than on the toes, he will go low on the pasterns, so that his feet, through weakness, become subject to false quarters, gravelling, &c.

Others are rugged, or brittle-hoofed: when the hoof is not smooth, and full of circles like rams horns, it is not only unseemly to the eye, but even a sign that the foot is in no good temper, but too hot and dry.

Some hoofs are long, which cause the horse to tread all upon the heels, to go low in the pasterns, and by that means to breed wind-galls.

There are some crooked hoofs, broad on the outside, and narrow on the inside, whereby the horse is splay-footed; this will oblige him to tread more inward than outward, and go so close with his joints together, that he cannot well travel without interfering, or perhaps striking one leg so hard against the other as to become lame; but if it be broad within, and narrow without, that is not hurtful, yet will occasion the horse's gravelling more on the outside than the inside.

Others have flat hoofs, and not hollow within, which give rise to the inconveniences above specified in the first sort of imperfect hoofs; but if it be too hollow, it will dry the faster, and make him hoof-bound, since the too hollow hoof is a strait, narrow one, and grows upright; for though the horse treads upright, and not on his heels, yet such kind of hoofs will dry too fast, if not continually stopped.

When the frush is broad, the heels will be weak, and so soft that you may almost bend them together, then he will never tread boldly on the stones or hard ground.

Some have narrow heels; they are tenderest; so that at last the horse will grow to be hoof-bound.

HOOF-BONY, is a round bony swelling, growing upon the very top of an horse's hoof, and always is caused by some blow or hurt, or by bruising himself in his stall, by endeavouring to strike at a horse that stands next him, and so strikes against the bar that parts them.

The cure is, first to digest the swelling, either with rotten litter, or hay boiled in old urine, or else with a plaister of wine-lees and wheaten flour boiled together, to ripen it and bring it to a suppuration, or dissolve the tumour.

But if it comes to a head, lance it in the lowest part of the softness, with a thin hot iron to let out the matter.

Tent it with turpentine, deer's suet, and wax, of each equal quantities melted together, laying a plaister of the same salve over it, to keep in the tent till it be thoroughly well.

HOOF-BOUND in a horse, is a shrinking of the hoof at the top, and at the heel, which makes the skin start above the hoof and so grow over it.

It may happen to a horse divers ways; either by keeping him too dry in the stable, by strait shoeing, or else by some unnatural heat after foundering.

The signs of it are, he will halt much; his hoofs will be hot, and if you knock them with a hammer, they will sound hollow like an empty bottle.

As for the cure, that being the proper business of the farrier, I shall omit to prescribe for it here.

HOOF-BRITTLE. An infirmity in horses, proceeding either naturally or accidentally; naturally, from the fire or dam; accidentally, from a surfeit, that falls down into their feet; or else from the horse's having been formerly foundered.

For the cure, take unwrought wax, turpentine, sheep's suet, and of hog's-grease, of each four ounces; salad oil, a quart

quarter of a pint; and of dog's-grease, half a pound: boil them all together, and keep them in a gally-pot for use.

With this anoint the hoof well for two or three days, especially at the setting on of the hair, and stop them with cow-dung and hog's-grease melted together.

HOOF-CAST, or, *casting of the hoof*, is when the coffin falls clean away from a horse's foot.

HOOF-SWELLED. An infirmity that sometimes happens to young horses by being over-ridden, or too hard worked, which causes them to swell in that part, by reason of the blood falling down and settling there, which, if not speedily removed, will beget a wet spavin.

It proceeds from some founder, prick, or slap, breaking on the top round about the coronet, which in time causes it to fall off.

For the cure: take the strongest aqua-fortis you can get, and first file or draw away the old hoof somewhat near, with a file, or drawing-iron; then touch the hoof, so prepared, three or four dressings or more, with the aqua-fortis, and anoint the foot with an ointment, made of one pound of hog's-grease, patch-grease three quarters of a pound; Venice turpentine, five ounces; new wax, three ounces; and sallad oil, three ounces; all melted together over the fire: the coffin of the foot up to the top, being anointed with this, a new hoof will grow on it.

HOOF-LOOSENED, is an infirmity in a horse; it is a dissolution or dividing of the horn or coffin of his hoof from the flesh, at the setting on of the coronet.

Now if the parting be round about the coronet, it proceeds from his being foundered; if in part, then by a prick of some channel-nail, quitter-bone, retreat, gravelling, cloying, or the like.

When the hoof is loosened by foundering, it will break first in the fore part of the coronet, right against the toes, because the humours also are disposed to descend towards the toe.

But if it proceeds from pricking, gravelling, and the like, then the hoof will loosen round about equally at first; but if it be caused by a quitter-bone, or hurt upon the coronet, it will break right above the grieved part, and is very rarely known to go any farther: as for the cure of the former, they are properly the business of a farrier.

HOOP, a measure equal to a peck, or quarter of a bushel.

HOP, a well known plant of the reptile kind, whose flower is a principal ingredient in beer, and other malt liquors.

A rich, deep, mellow, dry soil, rather inclining to sand than clay, is, in general, best adapted to the cultivation of hops; but a black garden mould is excellent for this purpose. Stiff clays, spewy lands, such as are apt to be overflowed by floods, hard gravels, stony grounds, very sandy ones, and such as are not at least a foot and an half deep, are altogether improper for hops.

The best situation for hop-grounds is such as inclines to the south, or lies open to it, so that they may have the benefit of the sun during the greatest part of the day. It must also be open, for the air to have a free passage and circulation between the plants, and it should be so sheltered to the east, north, and west, that neither the frosty winds in the spring may cut off the young sprouts, nor the more stormy ones in summer and autumn destroy the full grown hops.

The ground and situation being chosen, the next business is to prepare it for the planting. In many parts of England, when the ground is broken up for this purpose, the plough goes first, and men follow it with the spades, with which they dig one spit deep in the furrows where the plough has passed, throw up the earth thus dug, and so continue to plow and dig till the whole is done. Either this tillage, if it be well performed, or the deep ploughings, cross-ploughings, and harrowings, by which careful husbandmen prepare their land for corn, will fit this for being sown with turnip seed in the end of July, or beginning of August; and if the turnips are hoed twice, so as to be left about eight inches asunder, they will yield a good crop, the weeds will be destroyed, and the ground will be rendered loose and fine. Another good ploughing after the turnips are taken off, will, with the ensuing winter mellowing, render it fit for being planted with hops in the spring.

The best time to begin ploughing is in October, in order that the soil may be properly prepared to receive

the benefits of the winter's frosts, rains, and snows; after which, in the beginning of spring, it should be well and deeply ploughed again, and well harrowed; and after another ploughing in March, which will be of very great service, it should be harrowed fine, and laid as even as can be.

When the ground is in proper readiness for planting, stretch along a straight side of the field, at fifteen or twenty feet distance from the hedge, and parallel to it, a line with knots or rags tied in it, as far asunder as you design your hills to be, and stick in the ground a sharp-pointed stick at every knot, as marks for the places where the hills are to be made; continue the line in this manner the whole length of the ground, and from this first row you may mark out the rest of the field, either in squares, chequer-wise, at the intended distance of the hills, or in the quin-cunx form, where the hills of every row lie opposite to the middle of the first, in a triangular form.

The distance of the hills should be, in some measure, regulated by the nature and goodness of the soil: but, in every case, they should be far enough asunder to admit the hoe-plough at all times without danger to the plants. If the soil be dry and shallow, six or seven feet will be a convenient distance: but if it be rich, moist, and apt to bear large hops and leaves, it may be right to allow eight or nine feet between the hills.

The most proper season for planting hops, is from the beginning of March to near the middle of April, at the time when they begin to shoot. The Kentish husbandmen approve likewise of October: but the common sorts are not to be procured then, unless it be from a ground that is to be dug up or destroyed; besides which there is some danger of their rotting in the earth, if the winter should prove very wet.

There are several sorts, though the botanists allow but one species of hops. The most esteemed are, the long white, the oval, and the long square garlic hop. These differ from each other in the colour and shape of their bells, or hops, in the degree of bearing, and in their time of ripening. The long white is most valued, because it is a great bearer, and produces the most beautiful hops; for the beauty of hops consists in their being of a pale bright green colour. The oval hop is beautiful, but does not yield so large a crop. There is a sort of this kind of white hop, called the early, or rath hop, which ripens a week or ten days before the common, and is therefore of advantage to those who would be first at market: but it is tenderer than the other, and does not bear near so plentifully. The long square garlic hop is the greatest bearer, more hardy, and somewhat later ripe than the former; but by reason of its redness towards the stalk, it is not so beautiful to the eye, and therefore is not so much esteemed as the other sorts.

Few hop grounds are without some plants of a sort of hop which many call the female hop, but very erroneously; for the female hop is that which is cultivated for use, and this, which others name more properly the wild hop, is the male. Towards the middle of July, it puts out a great number of long loose bunches of small flowers, not at all like the true hop; and in somewhat less than a month after, that is to say, just before the true hop begins to blossom, they ripen, and with the least motion of the wind shed a farina, which is wasted all around, and is by some, not improbably, thought to be of use to impregnate other hops. Those who are of this opinion advise, therefore, to leave one or two hills of them standing in the hop-ground. But the common practice is to mark them at their first appearance, and to root them out afterwards, because they do not bear bells or hops, and as they are generally the strongest plants, sets might otherwise be taken from them by mistake.

There is also a poor starved hop, called a wild hop, which is not judged to be a distinct sort, but a hop which has degenerated for want of culture.

The planter of hops ought to be extremely careful in the choice of his plants, or sets, particularly in regard to the kind of the hop; for it is a great trouble and loss to him, when his garden proves to be a mixture of several sorts of hops, ripening at different times. He who plants the three sorts abovementioned, viz. the early, the long white, and the square hop, in three distinct parts of his ground, will have the convenience of picking them successively as they become ripe.

Hop sets are cuttings from the roots or branches which grow

grow from the main root or stock: They should be procured, if possible, from grounds planted with none but the sort which is desired; and they should be from five to seven or eight inches long, with three or more joints or buds on them, all the old blind and hollow part of the set being cut off.

The ground being prepared for planting, as before directed, towards the latter end of February, or in the beginning of March, if the soil be light, or late in March, if it be strong and moist, make, in the places marked out by the sticks stuck in them, holes about twelve or sixteen inches wide, and of a depth proportioned to the nature of the ground. In general, ten or twelve inches will be a sufficient depth. If the ground be shallow, and you meet with hard clay or gravel, by no means enter into this, for you would then make a basin to retain water; but, in such case, instead of going deeper, raise up a small hill of good mould. If there is a good depth of rich mellow mould, dig the hole a foot and a half, or two feet deep; and you will find the hops thrive the better; for their tap roots naturally run downward.

When all things are ready for planting, fill up the holes with the mould before thrown out of them, if it be naturally good, after having first broke it fine with a spade: but if the same earth be not rich enough make use of fine fresh mould, or of the compost provided for this purpose. About a peck or two of this will be sufficient for each hill; but no new dung should be put into the hole on any account.

Then, with a dibble, or settle stick, such as gardeners generally use for planting of beans, make five or six holes, the depth of your sets, one in the middle, perpendicular, and the rest round about, sloping and meeting at the top near the center: put your sets therein, so that they may stand even with the surface of the ground; and then press the mould close to them, and cover them with fine mould two or three inches thick. A stick should be placed on each side of the hill to secure it.

The ground being thus planted, all that is to be done in the following summer, is to keep the hills and alleys clear from weeds by frequent hoeings; to dig the ground in the month of May, and to carry off all the stones that are turned up by digging; to raise a small hill about the plants; to throw some fine mould on their roots; and, in the latter end of May, or beginning of June, to twist all the vines and branches together into a bunch or loose knot, and lay them thus twisted on the top of the hill.

Towards the latter end of February, or in the beginning of March, in the second year, when the weather is kindly, open the hills, and with a sharp knife, cut off the shoots of the first year to within an inch of the old stock, together with all the younger suckers that have sprung from the sets, and cover the stock with fine earth. To keep the knife sharp, you should have a whetstone always by you at dressing.

In the third and following years, when you dig your hop-ground in February, let the earth be taken away with a spade or hoe, round about the hill, very near them, that you may the more conveniently come at the stock to cut it: then in fair weather, towards the beginning of March, if your hops be weak, begin to dress them; but if they are strong, and in heart, the middle or latter end of March will be the best time; for late dressing restrains their too early springing, which is the cause of many injuries to the hop.

After the hops are dressed in the second year, the next business is to pole them. Poles of only ten or twelve feet long will do then; but in the third year, by which time they come to their full bearing state, they will require poles of full size: this, if the ground be rich, and the hop vigorous, will be from sixteen to twenty feet, or even more; or there will be danger of losing great part of the crop.

If the hop be weak, and the ground not rich, the poles should not be more than from fourteen to eighteen feet long, for fear of impoverishing the root; for the hop will soon run itself out of heart if over poled; so that, as was said before, there is more danger in over poling than in under poling; neither can a good crop be expected from an over poled ground, because the branches which bear the hops grow very little till the buds have over-reached the poles, which they cannot do when the pole is too long. Two small poles are sufficient for a hill in a young ground.

Towards the latter end of July hops begin to blossom; about the beginning of August they bell, and, in forward years, they are sometimes ripe at the end of August, or beginning of September. When they begin to change colour, or are easily pulled to pieces, when they emit a fragrant smell, and when their seeds begin to look brown and to grow hard, you may conclude that they are ripe: then pick them with all expedition; for a storm of wind will do them great mischief at this time: and hops picked green and bright, without bruising or discolouring, will sell for a third part more than those that are otherwise.

When the poles are drawn up in order to be picked, the vines around them should be cut asunder, at the height of about three or four feet from the ground; for the cutting of them lower, especially while the hops are green, would occasion so great a flowing of the sap, as would weaken and hurt the root.

The most convenient way of picking them is into a long square frame of wood, called a bin. This frame is made of two poles, or pieces of wood, each nine or ten feet long; and three or four inches broad, joined together at about a foot and a half from each end, by two other pieces three feet long; and it is supported by four legs three feet and a half high; so that there remain in the middle of it a space six feet long, three wide, and three and a half deep. In this space is fixed a coarse linen cloth, or hop-bag, cut open on one side, and hung hollow, either by hitching it on tenter-hooks along the inside of the frame, or by stretching it on the outside with wooden skewers, to receive the hops as they are picked. Three men or women, or four boys or girls, may stand on each side of the frame, and pick two poles at a time.

When you have raised some poles, bring them with the hops and vines on them, and lay them lengthwise upon the frames; or erect a forked prop at each end of the frame, and rest the poles thereon, in order to their being picked. There is no occasion to strip the vines from the poles in order to their being picked. The workmen who raises the poles generally carry them to the frames, and the latter being very light, may be easily removed from one part of the ground to another.

The ripest hops should be first picked: but if the hops appear to be equally ripe in all parts of the plantation, it is best to begin to pick them on the east or north-side of the ground, the more effectually to guard against the south-west wind's breaking into the garden.

Having chosen a spot of ground which contains eleven hills, place the bin upon the hill which is in the center, and after these are picked, remove it into another spot of the same extent, and so proceed till the whole is finished.

The hops should be picked as free as possible from leaves and stalks: for these would be of greater prejudice to the sale, than any seeming advantage which might be expected from their weight. The bin should be emptied two or three times a day into a large cloth of coarse linen, in which the hops should be immediately stitched up with skewers, and carried directly to the oast, or kiln, to be dried: for if they remain long in the bin, or cloth, they will sweat and be discoloured.

If any brown hops are met with in the picking, care should be taken to separate them from the rest, by putting them into a basket by themselves.

If the weather be very hot, or rainy, cut no more hops than may be picked in an hour: but, if it be possible, gather them in fair weather only, and when they are dry; for this precaution will save some expence of coals, and contribute to the better preservation of the colour when they are dried. No hops should be gathered when the dew is on them, for that would make them become mouldy.

When you have taken the poles from the hills, twist together the remaining ends of the binds, that they may not get among the people's legs, and hinder their work.

Before you draw the poles, observe whether the hops on one pole be entangled above with those of another, and if they are, cut them asunder with a sharp hook fixed at the end of a long pole.

If the garden be large, it may be worth while to raise a shed in the midst of it, to shelter the pickers and the hops from the sun and rain; and to lay hops in over-night, to be picked early the next morning before the dew is off the other hops. This shed will also serve for preserving your poles in winter.

If there be either rain or dew upon the hops at the time when they must be gathered, shake the pole, and they will dry

dry the sooner. If they are over-ripe when gathered they will shed their seeds, in which the chief strength of the hop consists; nor will they then look so green, but somewhat brown, which is a great diminution of their value. It therefore is better to pull the hops, a little before they are ripe, than to wait till they are full ripe. Four pounds of undried hops, thorough ripe, will make one pound of dry; and five pounds of hops scarcely ripe, though in their full prime, will make no more when they are dried.

There are two principal sorts of hops, viz. the green and the brown. The former yields by much the best colour when dried, and the other is the most plentiful bearer.

Brown hops are fit for brown ale, but the hops for fine pale beer must be green; for which reason these last are most esteemed.

As fast as you pick hops, dry them on a kiln; otherwise they will change colour: but if you cannot dry them immediately, and must keep them a little while, spread them on a floor, and by that means the damage which they will receive in a day or two will not be great. They who have five or six acres of hops, may employ ten frames at a time in picking.

If any of the rath-ripe, or early hops, which blossom and ripen a week or ten days sooner than the other sorts, happen to be intermixed in the same plantation, they should be watched carefully, in order to their being gathered in time; for if they hang till they are over ripe, they will shed their seeds, turn brown, and thereby not only become bad themselves, but spoil the sale of the others with which they are mixed. It is therefore advisable to mark at the blossoming season, the hills in which they are, in order to dig them up and replant those spots; for the trouble of pulling them up separately, when they are scattered here and there in a hop-ground, and of carrying them sometimes a considerable way, to a convenient place, to be picked, is very great, and cannot be avoided otherwise than by either banishing them totally, which would not be quite consistent with the husbandman's profit, as they fetch a good price by their coming first to market; or, which is the best way, by planting them in a garden by themselves.

Very particular care should be taken that the hops be thoroughly and equally dried. In this lies the greatest difficulty in the art and management of them: for if they are over-dried, they will change colour, look brown, and be judged to be burnt, whereby their value will be greatly diminished; and if they be under-dried, they will lose their colour and flavour. Experience has shewn, that an handful only of under-dried hops spoil many pounds of others, by taking away their fine smell and colour.

The best way of drying them is with a charcoal fire, on a kiln covered with hair-cloth, of the same form and fashion as is used for drying of malt, under which head this common sort of kiln will be more particularly spoken of hereafter. It is found to suffice in places where only a few hops are raised, and a great deal of malt is made: but where the hop-planters have a much greater quantity of hops than can be dried in due time on their malt-kiln, (for hops, as was said before, ought to be dried as soon as possible after they are picked), they build, in the following manner, several small kilns on purpose for drying of hops.

Eight or ten acres of hop-ground require a building of about sixty feet long, and fifteen wide in the clear. At one end of this building is a boarded room, to receive the green hops which are brought from the hop-ground, and which lie spread out there, till there be room to put them on the kilns: at the other end of the building is another large boarded room, for receiving the hops from the kiln when they are dried, and for them to lie in heaps to sweat till they are fit for bagging. In the intermediate part of the building, three or four kilns, of eight or ten feet square each, are constructed thus, close to one another.

If the middle-building is, we will suppose, twenty-eight feet long, and fifteen feet wide, there will be room for three kilns of eight feet square each on the clear, and for their respective walls. These kilns should lie in a line along the back wall, and will come forward above nine feet; so that there will remain a passage five feet wide and twenty-eight feet long at the front of their kilns.

To form each kiln, build the walls of brick, nine inches thick, and let each of the four sides be eight feet long in the clear, and seven feet high. The principal parts of the kiln are, in the upper part, the bed or floor whereon the hops are to be laid, in order to their being dried; and in the under part, the furnace, steddle, or lanthorn, for the fire. The

bed or floor in a kiln of eight feet square, should be about six feet from the lower floor, so that it will be about a foot below the top of the wall. This foot of wall rising above the bed, serves to keep in the hops on the kiln, and for men to walk upon round about the kiln, to look to the drying of the hops. The bed, or floor, may be made of wooden rails an inch square, laid very even and level, into a cross beam, a quarter of an inch asunder: or if the kiln be arched below, the floor may be laid with long bricks or stones resting on the tops of the arches, at about two inches distance from each other.

In making the lower part of the kiln, place the mouth of the furnace at the bottom, in the middle of the front wall of the kiln, and let it be fourteen inches wide and sixteen high. Joining to the mouth of the furnace on the inside, build the steddle or lanthorn, of brick, four inches thick. This lanthorn should be fourteen or sixteen inches wide, three feet perpendicularly high in the side walls, and it should reach from the front wall of the kiln to within a foot and an half of the back wall, so that there will be room for a man to pass between it and the back wall, and the length of the lanthorn thus made will be about six feet. On its side walls, bricks of a foot length are to be raised on their ends, leaning to and bearing upon one another; so as to form a covering like the roof of a house; or the top of the lanthorn may be regularly arched over.

In building the side walls of the lanthorn, after you have laid the two first rows of brick, leave at the end of every brick, in the three or four following rows, an open space or hole, four or five inches wide, chequer-wise, both in the sides and in the back, and lay the uppermost row or two of bricks close together, as in the bottom rows, for the better support of the roof. By this means there will be three or four rows of holes, which are designed to convey the heat equally to all parts under the hair-cloth. The roof should be well plastered on the inside with hair and lime, that it may the better reflect the heat.

In the front-part of the kiln, on one side of the furnace, and at the height of two feet from the ground, a small door should be made, three feet high, and two wide, so that a man may easily get in to set every thing to rights about the steddle. There should also be steps or stairs to go to the upper floor, where the hops are dried; and as there is a passage below, five feet wide, along the front of the kilns; so will there be, directly over head on the upper floor, a like passage, which will be of use for bringing green hops from their room, and laying them on the kiln, and for carrying them to the store-room after they are dried. For greater conveniency, both these rooms should be on the same floor as the upper-part of the kiln.

A farther caution necessary to be observed, is that no holes be made within a foot of the fire-place or mouth of the furnace, and that all the parts about the kiln be constructed so close that no wind or air may possibly get in. The farther end of the steddle should be built of brick up to the top, with holes in it, as in the sides.

The kiln should be square, and may be ten, twelve, or fourteen feet over at the top; but there should be a due proportion between the height and breadth of the kiln, and the size of the steddle where the fire is kept, viz. if the kiln be twelve feet square on the top, it should be nine feet high from the fire, and the steddle should be six feet and an half square; and so proportionably in other dimensions. These kilns are made at a small expence.

In drying of hops, first lay the hair-cloth very even on the bed or floor of the kiln, and spread the green hops thereon, about six inches thick, laying them with a rake as smooth as possible, not thicker in one place than another. Let the kiln be moderately warmed before you lay on the hops; then keep an even and steady fire under them, but not too fierce at first, for fear of scorching them; and let not the fire slacken, but rather increase it till the hops are nearly dried, lest the moisture or sweat, which the fire has raised, fall back and discolour the hops. For these reasons chiefly it is, that no cool air should be suffered to come into the kiln while the hops are drying, and that wind, which would make the fire burn too violently, should not be permitted to blow on the mouth of the furnace. After the hops have lain thus about seven, eight, or nine hours, having left off sweating, and leap up when beaten with a stick, then turn them upside down with a broad malt-shovel, or scoop made for that purpose, or cast them up into a heap in the middle, and afterwards spread them equally on all sides. Let them remain in this situation for two

two or three hours more, till every hop, if possible, be thoroughly and equally dried; and then with a hair-cloth, remove them to the heap where they are to lie till they are bagged. If they do not dry in one place so much as in the rest, which may be perceived by touching them with a stick or wand, and observing whether they rattle when so touched, as they will do when dry; make them thinner in the places where they rattle least. They must not be turned while they sweat; for that will burn them, and make them lose their colour. The fire may be diminished a little before they are turned, and refreshed again afterwards: but those times excepted, the heat should be as equal as possible.

Hops are fully dried when their inner stalks become brittle, and break short on rubbing, and when their leaves fall off easily, and feel very crisp. When they crackle and leap a little, as they will do upon the bursting of their seed, then is the time to take them off the kiln.

If the fuel used for this purpose be either wood or turf, it should be charred first, because smoke spoils the colour and smell of hops. Charcoal made of old rotten poles is most commonly used. Cinders of sea-coal are also very good, and it is found by experience that Kilkenny coal dries hops perfectly well, because it does not smoke, and gives a constant uniform heat for a long time. The fire should be made at the mouth only of the furnace: for the air will disperse the heat sufficiently from thence to all parts of the kiln: and that it may be constantly of the same gentle degree, neither too strong nor too weak, it may be of service to make use of a thermometer, by marking upon which the degree of heat proper for drying hops, as soon as that degree is ascertained by experiment, you may always after know how to regulate your fire with great exactness: for, putting the thermometer within side the kiln for a short time, you may observe, by the height of the liquor, when the heat is come to a right pitch, and when it is either too high or too low, and so increase or slacken the fire accordingly. Any servant may, with the help of this instrument, be able to mend and correct the fire with great certainty, and not be liable to commit mistakes, which often prove exceedingly detrimental to the hops. When you begin drying, lose no time in the prosecution of that work, but employ people night and day, to attend it with the utmost care, till it be finished. A large malt-shovel full of charcoal, thrown into the mouth of the furnace of a kiln eight feet square, will last an hour.

It is observed that hops dried in the sun lose their richness of flavour, as other herbs do when they are dried that way. If they are laid on a floor to dry, without using a fire, they will lose their strength, be apt to sweat or ferment upon change of weather, and not be fit for packing. Fire exhales their watery parts, and, by retaining the oily, preserves their flavour and colour.

Hops break all to powder if they are bagged hot from the kiln. To prevent this, they should be laid in a heap, to sweat and grow tough; and if they are then covered for a while close with blankets, to keep the air from them, they will bag the better. There is no limited time for their sweating, that varying according to the weather: three or four days are commonly sufficient: but it is a certain rule, that when the hops feel moist and clammy, and can be squeezed in the hand, or trodden close, without breaking, they are then fit for bagging. The harder they are trodden, the better they will keep.

The bags proper for this occasion are made of coarse linen cloth. They are commonly about eleven feet long, and near two yards and a half in circumference, and contain about two hundred and a half weight of hops. The small bags, called pockets, contain about half that weight.

The manner of bagging is thus: make a round or a square hole, but a round one is most convenient, about twenty-six or thirty inches over, in the floor of the chamber where the hops are laid in heaps after they are sweated. This hole should be large enough to receive the bag, and for a man to go up and down it with ease. Tie with a piece of pack-thread, an handful of hops in each lower corner of the bag, to serve as handles for the more easy lifting or removing of the bag; and, with pack-thread, fasten the mouth of the bag to a frame, or hoop, somewhat larger than the mouth of the hole, that the hoop may rest on its edges, and strong enough to bear the weight of the hops when the bag is full, and of the man who treads

them. The upper part of the bag being thus fixed by the hoop, let the rest of it hang down through the hole; but not so near to the lower floor as to touch the ground: then throw into it a bushel or two of hops, and let a man go into the bag, and with shoes that have no heels, tread the hops down on every side, as hard as he can, till they lie close. Let more hops be then cast into the bag, and be trodden down as before; and continue this till the bag is full. When that is done, untie it from the hoop, let it down, and sew up its mouth as close as you can, observing at the same time to tie up some hops in the upper corners, as was done before in the lower. The harder the hops are pressed, and the closer and thicker the bag is, the longer and better the hops will keep.

When they are thus bagged, lay them upon a boarded floor, and in a dry place; for dampness would injure them greatly. At the same time all proper measures must be taken to guard against rats and mice, which, though they do not eat hops, are very apt to spoil them, by making nests and lodging in them.

Some, in treading the hops, use a fifty pound weight, fastened to a rope, and placed in the middle of the bag. The man in the bag treads about with his feet, and lifts it up now and then, to press them the closer together.

As soon as the hops are picked, strip their haulm or vines from off the poles, and, as your last work, lay the poles up so that they may be preserved. This is done either by stacking, piling, or housing.

The stacking is performed thus: set up three poles, like an erect triangle, or rather six poles, let into the ground with an iron crow, and placed circularly, but inclining to one another so as to meet; and be tied fast together with bands of the haulm of the hops, within a yard of the top. The poles destined for the same stack should then be erected speedily against this frame; for if they are suffered to lie on the ground, especially in wet weather, they will receive more damage in a fortnight, than by their standing out upright all the rest of the year. When they are set up, about three hundred to a stack, bind them round with a rope of twisted haulm, to keep them together. By this means the outer poles only are subject to the injuries of the weather, and keep all the inner ones dry, excepting at their tops and bottoms, the former of which are for the most part exposed to the air, as the latter are to the moisture of the earth. It is therefore a good method to cover the top of the stacks of poles with haulm, and to lay stones, bricks, or sand, at their bottom, to preserve their butt ends from rotting.

Many chuse to pile them up lengthwise, in different parts of the hop ground, laying three or four old poles athwart at bottom, to preserve them from the dampness of the earth, and setting several poles erect in the ground on each side of the pile to prevent its slipping: they then lay the poles on one another, placing the smaller ends inwards, and the bigger outward; so that the pile should consequently be somewhat longer than the poles: and when it is raised high enough, they bind it across with ropes of twisted haulm, to keep it upright and steady, and then cover it with haulm, to defend the poles from rain. This is a better method than the former; but the best way of all to preserve the poles, is to build in the hop ground a shed or two, which may serve as a shelter for picking the hops in summer, and laying up the poles in winter, with least danger of their being hurt or stolen.

From October to March, there is nothing to be done in the hop-ground, but to provide and bring manure into it, and to give the alleys their winter's digging or ploughing.

If you bring dung into your ground, be sure it be well rotted, and lay it on the alleys to mix with the earth, but not on the hills, dung being apt to produce vermin, which are extremely injurious to hops. Cold dungs, such as cows and hogs-dung, are better for hops than horse dung, unless the soil be cold and wet, and then hot dung, such as that of sheep, and even of pigeons, will not be improper.

A small dunging every second year is sufficient, and a plentiful dunging will serve for three years, if the soil be tolerably good.

Dung was formerly more in use for hop grounds than it is at present, experience having shewn, that lime, lime-stone, gravel, sea-sand, marle, especially the shelly marle, ashes, and many other manures, are the most proper means

of correcting the defects of soils, answer the end better, and last much longer.

The management of the hop-ground during the third and every subsequent year (for it will continue to yield good crops during upwards of twenty years, if it be rightly cultivated) is the time as above directed; so that it will require pretty constant care and attendance, especially from the beginning of March to the end of September. This you may lay down as a certain rule, that the more pains you take, and the greater expence you are at, in the due culture of the ground, and management of the hops, the greater will be your profit.

The charge of an acre of hop-ground, in most parts of England where hops are cultivated, is computed thus; three pounds for the husbandry, four pounds for the wear of the poles, five pounds for picking and drying, one pound ten shillings for dung, one pound for rent, and ten shillings for tythe; in all, fifteen pounds a year: but in some places they pay four or five pounds an acre yearly for the rent of the land.

The hop planters in England commonly agree with hop-dressers, to do, for three pounds to three pounds ten shillings an acre, all the husbandry part, in which is included the summer and winter digging of the ground, the pruning and dressing of the hops and hills, the poling and tying, several hoeings and making up the hills from time to time, the laying of the dung on the ground, and all other works, except the bringing of the dung to the ground, and the picking and drying of the hops, which last businesses are performed by others; so that a gentleman has little trouble with his hop-ground: he need only be careful that the undertaker does every part of the work in its proper season; and it is so much the interest of the undertaker to be punctual in this, that, if he neglects hoeing when the weeds appear, he will, by such neglect, greatly multiply his trouble and labour in rooting them out afterwards.

An English acre requires about three thousand poles, the price of which varies according to their size. In several places it is usual to give as many shillings for an hundred poles as the poles are feet long; so that for an hundred poles of twenty feet long they give twenty shillings; but where poles are in great plenty, they give but fifteen shillings for those of that length. A recruit of five hundred poles yearly will keep an acre of hop ground in constant repair; so that poles are about a third part of the yearly charge, the picking and drying are estimated at another third, and the rest is laid out in the managing of the ground.

The hop planters in England reckon, that they have but a moderate return when the produce of an acre of hops does not sell for more than thirty pounds. They frequently have fifty, sixty, eighty, or an hundred pounds for an acre; nay, some have got considerably more than even this last sum for every acre of hops, at a time when the crops of other hop grounds have failed in general, and their's have succeeded. But if, on one hand, such extraordinary profit, being very uncertain, is not to be depended upon; so, on the other, it should not be passed over quite unnoticed, because it is among the chances which may make amends for failing years. Upon the whole, if the total charge of an acre of hops is computed, as above, at fifteen pounds a year, and its produce, at an average of years, at thirty pounds only, the clear profit from an acre will be fifteen pounds a year.

Though it be common in England to see ten, twenty, thirty, or more acres of hop ground in the hands of one man, and though some who spare neither care, industry, or expence, to make their plantations of this kind flourish, receive two thousand pounds a year for their hops, notwithstanding the high price of labour, manure, and every other article relating to their proper management; yet the intelligent husbandman will easily perceive, that it is not prudent for poor farmers, or men of small fortune, to engage far in this branch of improvement: for it requires a pretty considerable stock at first to cultivate a large plantation, to furnish it with poles, and to perform every other requisite. The expence will necessarily be great, and the undertaker must expect to lie out of his money for two or three years, before he can have any return of profit; and even when his hops do come to their bearing-state, and he is in hopes of making good the charges he has been at, a bad season may frustrate his expectation.

Small parcels of hops, suitable to the abilities of the farmer, for even the poorest may easily spare time and labour, to plant a few of them in a corner of his garden, or other ground, and to set sallies, willows, or ash, for poles in his hedges or elsewhere, will yield him a pretty profit, without his laying out any money: so that, in setting forth the expences and risk which attend the cultivation of hops, we mean only to caution the husbandman, whose circumstances are but middling, against embarking too far in this branch of agriculture.

Ground that is fit for the raising of hops, is also fit for the raising of hop-poles of one kind or other. But to be more particular: low, wet, cold, marshy, boggy soils, or such as are situated near rivers, are fit for all the aquatic sorts, such as poplars, abeles, alders, willows, osiers, and sallies, which produce hop-poles in four or five years from their first planting. If the soil be dry and warm, or a strong, mellow, rich loam, the ash and the chestnut, which makes the best poles for hops, will thrive greatly therein, and be fit for poles in nine or ten years from the time of setting them: and if these are planted around the hop-ground, they will both shelter the ground, and afford a supply of poles without the expence of carriage. Elms also are quick growers; and when they are planted close together, they shoot up tall and strait, and make good poles.

Ash and chestnut poles, but especially those of chestnut, are so tough and durable, that three sets of them will last twenty years: but poles of alder, poplar, abele, osiers, or sallies, soon rot, or become brittle; so that five sets of them, at least, will be requisite within that time. The aquatic kinds are therefore to be esteemed only for a first supply, till the plantations of ash and chestnut become fit for the future recruit of the hop ground.

Hops are, like other vegetables, liable to various accidents and distempers, the principal and most fatal of which are the fly, the fen, or mould, the mildew, and what the planters call fire-blasts.

The reverend Dr. Hales, treating of this subject in his excellent Treatise of Vegetable Statics, gives us the following account of the state of hops in Kent, in the year 1725, which he received from Mr. Austen of Canterbury, who was a very great planter, and an accurate observer.

"In mid April, not half the shoots appeared above ground; so that the planters knew not how to pole them to the best advantage.

"Upon opening the hills, this defect of the shoot was found to be owing to the multitude and variety of vermin that lay preying upon the roots, and of which the increase was imputed to a long and almost uninterrupted series of dry weather for three months before. Towards the end of April, many of the hop vines were infected with flies.

"About the 20th of May there was a very unequal appearance, some vines being run seven feet, others not above three or four, some just tied to poles, and some not visible; and this disproportionate inequality in their size continued through the whole time of their growth.

"The flies now appeared upon the leaves of the forwardest vines, but not in such numbers here as they did in most other places. About the middle of June the flies increased, yet not so as to endanger the crop; but in distant plantations they were exceedingly multiplied, so as to swarm towards the end of the month.

"On the 27th of June some specks of fen appeared. From this day to the 9th of July the weather was very dry. At this time, when it was said that the hops in most parts of the kingdom looked black and sickly, and seemed past recovery, ours held out pretty well, in the opinion of the most skilful planters. The great leaves were indeed discoloured, and a little withered, and the fen was somewhat increased.

"From the 9th of July to the 23d, the fen increased a great deal; but the flies and lice decreased, it raining much daily. In a week more, the fen, which seemed to be almost at a stand, was considerably increased, especially in those lands where it first appeared.

"About the middle of August the vines had done growing both in stem and branch, and the forwardest began to be in hop, the rest in bloom; the fen continued spreading where it was not before perceived; and not only the leaves, but many of the burs also were tainted with it.

About

“About the 20th of August, some of the hops were infected with the *fen*, and the whole branches were corrupted by it. Half the plantations had escaped pretty well hitherto, and from this time the *fen* increased but little: but several days of wind and rain in the following week distorted the plants so that many of them began to dwindle, and at last came to nothing; and of those which then remained in bloom some never turned to hops, whilst many of those which did were so small, that they scarcely exceeded the size of a good large bur.

“We did not begin to pick till the 8th of September, which is eighteen days later than we began before. The crop was a little above two hundred on an acre of ground, and not good. The best hops sold this year at Wey-hill, for sixteen pounds the hundred.”

As a farther means of investigating the cause of this pernicious distemper, Dr. Hales relates the following experiment, which he himself made on hops. In the month of July he cut off two thriving hop-vines, near to the ground, in a thick shady part of the garden, and left the pole still standing. He stripped the leaves from off one of these vines, and left them on the other, and then set their stems in known quantities of water in little bottles. That with leaves imbibed in a twelve hours day, four ounces, and that without leaves only three fourths of one ounce.

He took another hop-pole with its vines on it; and having carried it out of the hop-ground into a free and open exposure, these plants imbibed and perspired there double the quantity of the before-mentioned which had leaves on it in the hop-ground. This seems to indicate that the reason why the hop vines on the outside of gardens, where they are most exposed to the air, are short and poor, in comparison of those in the middle of the ground, is, because, being much drier there, their fibres harden sooner, and therefore they cannot grow so kindly as those in the middle of the ground, which, by the shade and shelter they afford each other, are always kept moister and more ductile.

From this perspiration of their fluid, the same attentive observer of nature forms the following calculations. There being a thousand hills in an acre of hop-ground, and each hill having three poles, and each pole three vines, the number of vines will be 2000, each of which perspiring four ounces, the sum of all the ounces perspired by an acre in twelve hours of day will be 36000, equal 1575000 grains, equal 62007 cubic inches, or 220 gallons, which being divided by 6272640, the number of square inches in an acre, it will be found, that the quantity of liquor perspired by all the hop-vines will be equal to an area of liquor as broad as an acre, and $\frac{1}{8}$ part of an inch deep, besides what is evaporated from the earth.

Now this quantity of moisture, in a kindly state of the air, if daily carried off, is sufficient to keep the hops in a healthy state: but in a rainy moist state of air, without a due mixture of dry weather, too much moisture hovers about the hops, so as to hinder, in some measure, the kindly perspiration of the leaves, whereby the stagnating sap corrupts and breeds mouldy *fen*, which often spoils whole tracts of, till then, flourishing hop-grounds.

This was the case in the year 1723, when, for twelve or fourteen days, almost continual rains fell, about the latter half of July, after four months of dry weather; upon which the most flourishing and promising hops were all infected with mould, or *fen* in their leaves and fruit, while the then poor and unpromising hops escaped, and produced plenty, because they, being small, did not perspire so great a quantity as others, nor did they confine the perspired vapour so much as the large thriving vines did in their shady thickets.

The planters of hops remark, that when a mould, or *fen*, has once got possession of any part of the ground, it soon over-runs the whole, and that even the grass, and other herbs under the hops, are infected with it. The reason probably is, that the exceeding small seeds of this quick growing mould, or moss (for such in fact it is) coming soon to maturity, are easily blown over the whole ground; and it is undoubtedly owing to the same cause, viz. to the remaining dispersed seeds of the preceding year's *fen*, that some grounds are infected with this distemper for several years running. The means pointed out for curing the moss on fruit-trees should therefore be assiduously recurred to here, at least so far as they can be applied to hops; and, at all events, particular care should be taken to

keep the land always in fine tilth, constantly free from weeds, and to burn all the fenny hop-vines, in a place remote from the garden, as soon as they are picked. We have already seen instances of the cure of moss upon fruit-trees, by the use of hog's-dung; and there is no room to doubt the efficacy of the same remedy when applied to mouldy, or mossy hops.

Mr. Austen, of Canterbury, observes that the *fen* is more fatal to those grounds which lie low, and are closely sheltered, than to such as have a high, and open situation; to those that look shelving to the north, more than to those whose slope is towards the south; to the middle of hop-grounds, more than to moist and stiff soils. This was very apparent throughout his plantations, where the land was prepared and planted in the same manner, and at the same time.

The mildew, which lights upon hops, is a white dew, that falls in summer at sun-rise, chiefly when the hops are in flower. Its fall is so unequal, that it sometimes embraces a whole district, and sometimes only parts of it. This dew dries up the hops, withers and consumes their leaves, and consequently ruins the crop. “There is,” say the authors of the *Journal Oeconomique*, whose account of this distemper, to which hops are extremely liable, we shall copy here, “no other remedy from nature against this mischance, except rain sufficient to wash the plant, and clear it entirely from the fatal dew: but as rain seldom comes quite seasonably to the relief of the plant thus affected, artificial means have been sought, for insuring it against this accident. Some have surrounded their hop-grounds with hogs-dung; others have employed persons to go through the ground with vessels full of beech-ashes, and to throw them upon the hops while the mildew was falling; and both sides, profiting by their experience, pretend to have found a specific preservative against the bad effects of the mildew. They have even proceeded so far as that each side affirm theirs to be the only remedy. Those who use hog-dung say, that the ashes may probably hinder the action of the dew upon the plant; but that they must, at the same time, stop up its pores, and deprive the soil of its humidity; a circumstance equally ruinous to the plant: and that, besides, beech is not to be found every where, and if it must be brought from afar, the remedy would in some measure become impracticable, by the scarcity and difficulty of procuring it. The partizans of the ashes say, that they cannot comprehend how hog-dung laid round the hop-ground in the spring, should preserve such virtue as to destroy the bad quality of this mildew in the summer. In short, to render this discussion complete, each side alledges, that the trials which they have made of the other's remedy did not succeed.

“This dispute, the subject of which is highly interesting to all countries where beer is the common drink, excited a naturalist to examine the nature of this mildew; and with the assistance of a microscope he perceived it to be full of the eggs of little insects, which fly in vast numbers in the air while the hop is in blossom. These insects gnaw the leaves even of trees, and like others of their species, undergo various metamorphoses. This discovery induced him to believe, that, as insects are not apt to attack perfectly healthy trees, or vigorous plants, but only such as are feeble and sickly (they being endued with such nice sensations as to distinguish by the outside only, perhaps by the smell, a plant which is vitiated within, though it may appear to us to be quite fair and sound) hog-dung might probably give such vigour to the hop, as to render these little animals afraid to attack it: for it has been remarked, that the insects which nip a leaf, leave it as soon as they find in it an abundant juice, the salts of which, it may be presumed, are too strong for them; and that they fix on those only which begin to decay and lose their sap. Ashes may likewise have the power of hurting them, and its salts may be capable of giving them disturbance. But late experience hinders us from giving entire credit to these two remedies, and shews, that if they have sometimes preserved hops from the effects of mildew, we are not to conclude that they will always answer this desirable end.

“A very good husbandman saw his hops spoiled by the mildew, notwithstanding the dung with which they were surrounded, and the ashes that were thrown upon them: in a little time the leaves of the plants were covered with millions of small white insects. The ashes, indeed, seemed to kill them; but, as was observed above, they at the same

same time deprived the soil of its necessary moisture. Desirous of saving his hops, he recollected an axiom in medicine, importing that bitter things kill worms: *amarum necat vermes*. He then ordered a quantity of wormwood to be bruised; and having infused it in water, he sprinkled his hops with the infusion, by means of a forcing pump; but he was too late, the hops being already destroyed. A clergyman in his neighbourhood, who was well versed in matters of agriculture, and to whom he related his bad success, answered that when such an accident happened to him, he, without giving himself so much trouble, ordered his people to strip off immediately all the leaves of his hops, and, that, the stalks pushing out other leaves, he had at least one half and sometimes two thirds, of his ordinary crop."

"The publication of the above account concerning hops," add the writers of the *Journal Oeconomique* (whom we continue to copy) in one of their subsequent papers, "has excited a skilful farmer to communicate his experiments on this subject. The reader will perceive, by the following extract of his letter, which we are impatient to publish to the world, the obligations that are due to him from all those who cultivate hops, and the credit he deserves in what he relates.

"I was informed some years ago, that hogs-dung might be employed to great advantage in hop-gardens: nevertheless, as I could not conceive the reason of the advantage which the hops derived from that sort of dung, I gave myself no trouble about using it preferably to any other; but having this last year lost almost all my hops by the mildew, and having observed but one single place where the fruit remained entire, and in a perfect state, I found, upon diligent enquiry, that my servants had laid hogs-dung upon that very spot, precisely where the mildew had not injured the fruit. I am therefore convinced of the good effects of this dung in hop-gardens, and the more so, as I am certain that my land was prepared with dung of all sorts. The farmer will therefore find his account in using for his hop-grounds all his hogs-dung (which, it is likewise to be considered, is in general thought to be the least serviceable to lands) and in covering his hop trenches, both in autumn and spring, with the same kind of dung new, before it is rotten."

The latter part of this letter is calculated for such general utility, that we cannot refrain from adding it here, though at the hazard of digression from the present subject. The directions given in it are indeed uncommon; but we can hardly suppose, that the writer of it would instance facts, without having a foundation for so doing.

"When hops are scarce, their leaves and sprigs ought to be gathered for several useful purposes; but they must be gathered with great care: no leaves should be taken, but such as are clean, young, whole, and green; and only the tips of the sprigs that are green, young, and full of juice. They must be dried in a very clean and airy place.

"These may be used in brewing, for an after-beer, or for common small beer; for by throwing in the leaves and sprigs of hops, that beer acquires an additional strength, becomes the more wholesome, and will keep the longer.

"The leaves and sprigs of hops are, during the excessive colds of winter, an excellent cordial to cattle, whom they strengthen most prodigiously. The method of using them, is to infuse them in boiling water, and to mix this infusion with the ordinary drink of the cattle.

"Cattle may be still more strengthened, by mixing with their drink the tops of pines or firs: and to render these the more efficacious, it is proper to boil them in a kettle, that all the resinous substances may dissolve, and to pour the extract into their drink. Some of my cows, then kept on a little farm, which is surrounded with mountains, were so affected by a prodigious cold, that the very marrow was almost frozen in their bones: they lay helpless upon the ground, and though the best of fodder was given them, could not use their limbs or rise up. I can ascribe to no other cause, than the remedy which I have just now pointed out, the surprising cure of these animals. In one month's time, they were so well recovered, that they rose without any assistance, and ever since they have resisted the most violent cold, without being in the least affected. The singularity of this event determined me to impart it to you, in order that every body may, upon the like occasion, have recourse to the same remedy."

As to the fire blast, as it is commonly called, we shall only add here, what Dr. Hales had related, that in the month of July, which is the season when this blight is most apt to

affect hops, he had seen the vines in the middle of the hop-ground scorched up almost from one end of a large plantation to another, when a hot gleam of sun-shine came immediately after a shower of rain; and that, at such times, vapours may be observed, with the naked eye, to ascend so plentifully, as to make an object, which was before clear and distinct, become immediately very dim and tremulous. It was therefore probably owing to the much greater quantity of vapours in the middle of the hop garden, than there was towards its skirts; and that middle being the densest medium, the rays of the sun may have been collected nearer to a point, by passing through that denser medium, than they were in the outer parts of the ground. The course of the scorch was at right angles to the beams of the sun about eleven o'clock, at which time the hot gleam happened. The hop ground was situated in a valley, running from south-west to north-east; there was very little wind, and that in the course of the scorch.

HOPPER, a kind of basket, in which the seed-corn is carried at the time of sowing. See the article DRILL-
PLOUGH.

HORN-BEAM, the name of a tree very common in many parts of England, and in some places cultivated for its wood, which is very hard and serviceable for many purposes, especially turnery-ware, mill-cogs, &c.

Horn's universal Five-furrow sowing Machine.

Mr. Young, in his *Annals of Agriculture*, vol. xii. says that "this most useful and celebrated invention, justly claims the attention of every occupier of land in the kingdom. The profits derived from the use of it, over and above what can be produced by the usual methods, will alone, in general, amount to more than the whole rent of the land, without any additional expence in the culture.

"It sows all sorts of grain and seed with equal regularity and ease; and the quantity of seed sown, can be varied readily, and in any degree. The machine also possesses the peculiar advantage of sowing turnips, so as to ensure the crop against the ravages of the fly, which is of great importance to many, and will, independent of every other advantage, make the machine a real treasure to most farmers, and give it a decided superiority over every invention yet offered to the public. This advantage is obtained by sowing the usual quantity of turnip-seed, broad-cast, by the machine, and at the same time striking furrows at a proper distance apart in the land; by this means part of the seed is deposited in the drills, and the rest sown broad-cast between them, so that if it proves a dry season, it is favourable for that deposited in the drills; if a wet season, for that which is sown broad-cast between them: and if that part of the seed which is sown broad-cast is carried away by the fly, that which is deposited in the drills, by coming at another period of time, is saved, and *vice versa*. If the whole grows, the farmer has then the opportunity of selecting the most vigorous plants from both."

HORSE, a well known quadruped, and one of the noblest animals we are acquainted with.

The most noble conquest ever obtained by man, was over this proud and spirited animal, which shares with him the fatigues of war, and the glories of battle. The horse, not less intrepid than his master, sees danger, and defies it; he inures himself to the din of arms; he delights in it, seeks it, and is animated with an ardour equal to that of man. He also shares with his master in the pleasures of the chace, the course, and tournaments; but his docility being equal to his courage, he is not carried away by impetuosity; but checks its impulses, and not only submits to the hand of the rider, but seems even willing to consult his desires. Ever obedient to the impressions he receives, he darts forward, slackens his pace or stops, as they happen to indicate: he renounces his very being, and exists merely by the will of another which he frequently anticipates, and by the celerity and precision of his motions, at once expresses and executes. He feels as much as is desired, and performs no more than the rider pleases; he gives himself up without reserve, and declines no service; exerts all his strength, and, that his obedience may be complete, will strain every nerve till he even expires under his generous efforts.

Such is the horse, whose talents are improved, and his natural qualities perfected by art: from his birth he is carefully attended, exercised, and fitted for the service of man: his education commences with the loss of his liberty, and is completed by restraint. The servitude of these animals is

to universal and perpetual, that we seldom see them in their natural state. When employed, they are loaded with harness; in the seasons of rest, they are not entirely free from shackles, and even in the fields and pastures, they carry the badges of slavery, and frequently bear the cruel marks of labour and pain. Their mouths disfigured with furrows, occasioned by the bit; their sides deformed with ulcers or cicatrices from the spur; their hoofs perforated with nails, and their attitudes, by the continued pressures of the harness, cramped and constrained; even those, whose servitude is of the easiest kind, being kept chiefly for shew and magnificence, and whose gilded chains are not so much intended for an ornament to them, as to display the opulence of their master, are still more disgraced by the elegance of their foretop, the plaiting of their manes, the gold and silken caparisons with which they are adorned, than by the iron fastened to their feet.

Nature is more elegant than art; and in an animated being, the freedom of motion constitutes the beauty of nature. Observe those horses in the American dominions of Spain, where they enjoy all the sweets of liberty; how elegant in their attitudes, their running and leaping! Free from all restraint and stiffness, they are proud of their independence; they fly from man, and disdain his care; they seek and find themselves proper food; range and frisk at liberty, in immense pastures, cropping the fresh product of a perpetual spring. No settled abode, no other shelter than the canopy of a serene sky, they breathe a purer air than in those vaulted palaces where we confine them in narrow spaces. Accordingly these wild horses excel most of their species in strength, fleetness, and vigour. In them spirit and dignity are the gifts of nature; the other possess only the gifts of art, viz. skill and gracefulness.

The nature of these animals is not ferocious, they are only wild and spirited. Though superior in strength, they never molest other animals; and if molested themselves, they despise to dispute, or trample upon the aggressor. They are attached to each other, and herd together; not through fear, but from a natural love of society. Grass and vegetables being all they desire, a sufficiency of food is never wanting; and not being carnivorous, they have no wars either with other animals or among themselves. They never dispute about subsistence, never contend with one another for prey or booty, the usual causes of quarrels and battles among carnivorous animals. Thus they live in peace; every individual has enough, and their appetites being simple and moderate, they never envy each other.

All these particulars may be observed in young horses brought up together; their dispositions are mild and gentle, the social qualities are seen in them, and their strength and mettle are conspicuous only in acts of emulation. They strive to excel in speed, and to accustom themselves to danger: they defy each other to cross a river, or leap a ditch; and those which, in these natural exercises, set the example, those which voluntarily lead the way, are always the best, the most generous, and often, when tamed, the most docile and tractable.

Some ancient authors mention wild horses, and even the places where they were found. Herodotus observes, that on the banks of the Hypanis in Scythia, were wild white horses; and he describes others in the northern parts of Thrace, beyond the Danube, clothed with hair five inches in length. Aristotle mentions Syria; Pliny, the northern countries; Strabo, the Alps and Spain, as countries that produced wild horses. Among the moderns, Cardan says the same of Scotland and the Orkneys; Olaus of Muscovy; Dapper of the isle of Cyprus, adding, that, its wild horses were remarkable for their beauty, swiftness, and strength; Struys of the isle of May, where there is a breed of wild horses extremely small. Leo Africanus relates that wild horses were found in the deserts of Africa and Arabia; and affirms, that he himself saw in the wastes of Numidia, a white colt with a frizzled mane. Marmol confirms this account, and observes that in the deserts of Arabia and Lybia, these animals are small, of an ash colour, and some of them white, with short bristled manes; and that neither dogs nor tame horses can equal them in fleetness. The Lettres Edifiantes mention very small wild horses in China.

All parts of Europe being at present inhabited, and almost equally peopled, wild horses are no longer to be found in it; and those in America came originally from tame horses bred in Europe, and carried over thither by the Spaniards, where they have since multiplied in the vast tracts of that uninhabited country; for this species of animals were wanting in the new world. The amazement and terror of the inhabitants

of Mexico and Peru, at the sight of the horses and the cavalry, sufficiently intimated to the Spaniards that the horse was unknown in these climates, which induced them to transport great numbers both for military service, private convenience, and the propagation of the species. Some they turned loose in different islands, and even on the continent, where they multiplied like other wild animals. Monsieur de la Salle, in the year 1685, saw some of these horses near the bay of St. Louis, in North America; but so wild that he could not come near them. The author of the Adventures of the Buccaneers says, "that in the island of St. Domingo, troops of above five hundred horses are often seen; that at the sight of a man they make a general halt; while one of them approaching within a certain distance, snorts, flies away, and all the rest follow him." He adds, that whether these horses have degenerated during their being wild, he cannot pretend to say; but he did not think them so handsome as those of Spain, though undoubtedly of that breed. "Their head and legs, he describes, as very large, the latter full of knots; their ears and neck long. The inhabitants easily tame them for their several employments, and the hunters load them with their hides. They are taken in toils, laid in places where they frequent, are easily entangled, and if by the neck, strangle themselves, unless some person happens to be ready to assist them. They are fastened round the body and legs to trees, and there left two days without either meat or drink. This renders them tame, and in time they become as tractable as if they had never been wild: and if they should by accident recover their liberty, they never regain their former wildness, but know their masters, and quietly suffer themselves to be retaken."

This demonstrates, that these animals, naturally mild, are very much inclined to become familiar with man, and attach themselves to him. Accordingly, none of them are ever seen to leave our dwellings for the forests and deserts; but, on the contrary, express the greatest desire of returning to their stables; though all they meet with there is a gross food, always the same, and generally measured out rather by parsimony than their craving appetites; but the kind treatment they meet with compensates for their other losses. When spent with fatigue, the place of rest is a place of delight: they smell it from afar; they find it out in the midst of the most crowded cities, and seem in every thing to prefer servitude to freedom. The habits they have contracted become a kind of second nature; horses left in the woods have been known to keep a continual neighing, in order to be heard; and at the voice of a man, have ran to him with transport: and amidst a rich variety of agreeable nourishment, while deprived of human society, they have been known to lose their flesh, and to become strangely emaciated in a very short time.

Thus education gives the whole turn to their manners; and this education requires an assiduity, care, and attention, that man will not bestow on any other creature; but the continued services of the horse makes him ample amends.

The finest horses known in Europe are the Arabian: they are larger and fuller than the Barbs, and not inferior to them in shape. But as few of them are imported into France, the riding masters have not made any circumstantial observations on their perfections and defects. The Barbs are more common, their chest is long and slender, rises beautifully from the withers, have little manes, the head well-shaped, small, and lean; the ears handsome and well-placed; the shoulders flat and slender; the withers narrow and plump; the back straight and short; the flank and sides round, and not belying out; the haunches firm, and well-shaped; the croup or breech generally somewhat long, and the tail pretty high placed; the thigh well-shaped, and seldom flat; the legs handsome, well-shaped, and without hair at the pastern joint; the foot well made; but the pastern often long. They are of all colours, but generally brown. The Barbs are something negligent in their goings; but, properly encouraged, shew an amazing swiftness and vigour; they are very light, and fit for running; and seem, of all others, the fittest to breed from. It were however to be wished that they were of a taller size, the very largest being only fourteen hands; and one of fourteen hands and an inch is very extraordinary. Experience has shewn that in France, England, &c. they get colts larger than themselves. Among the Barbs, those of the kingdom of Morocco are accounted the best, except the mountain Barbs. Those of the rest of Mauritania are inferior to them, as are also those of Turkey, Persia, and Armenia.

All horses from a hot climate have a smoother coat than others. The Turkish horses are not so well proportioned as the Barbs; the neck slim, a long body, and the feet too slender; but are very laborious and long winded. Nor will this appear strange, if it be considered, that in hot countries the bones of animals are harder than in the cold; and for this reason it is, that though their shank bones are smaller than the horses of this country, yet their legs are stronger.

The Spanish horses, which are placed next to the Barb in rank, have a long thick neck, with a large mane; the head full large, and sometimes the fore top large; the ears long, but well placed; the eyes full of fire, and the air noble and spirited; the shoulders thick, and the chest broad; the back often something low; the ribs round, but the belly often too large; the croup generally round and large, though in some longish; the legs beautiful and without hair; the finew well detached; the pastern sometimes longish like the Barbs; the foot a little lengthened like that of a mule; and the heel often too high. The fine bred Spanish horses are plump, well-set, and place the legs well on the ground; they have also a great deal of motion in their paces; great agility, fire, and stateliness. Their coat is generally black, or a light chestnut; though there are some of all the usual colours. But this is very seldom that any are seen with white legs or muzzles; the Spaniards having such a dislike to these marks, that they never breed from horses which have them. A star in the forehead is all they require; but they value horses of one entire dark colour as much as we despise them: both these prejudices, though opposite, are perhaps equally ill-founded, there being very good horses with all kinds of marks; and some excellent among those which are all of one colour. This minute difference in the coat does not proceed from the nature or constitution of the horse; but from an external, and at the same time so superficial a quality, that a slight wound in the skin is sufficient to produce a white spot: further, the Spanish horses, whether intirely of one colour, or not, are all marked on the off thigh with the mark of the stud where they were bred. They are not usually large sized; though some rise to fourteen hands and one or two inches. Those of Upper Andalusia are esteemed the best of all, though they are apt to have the head too long; but this blemish is overlooked in consideration of their excellent qualities; as courage, gracefulness, obedience, ambition; and in activity, they even exceed the Barbs. These advantages recommend them above all other horses in the world, whether for war, state, or the manege.

The finest English horses greatly resemble the Arabians and Barbs in shape; indeed they owe their origin to them; but the head is much larger, though well made, and has a fine fore-top; the ears longer, but properly placed. By the ears alone an English horse may be distinguished from the Barb: but the greater difference is in the size; the English horses are much larger and well-set. Their common height is fourteen hands two inches, and even fifteen hands is not very extraordinary. They are of all colours, and all marks; are generally strong, mettlesome, bold, bearing great fatigue, excellent for hunting and racing, but want air and agility; they are stiff, and have little freedom in their shoulders.

The Italian horses were formerly much finer than at present, the studs having been neglected there for some time past: the kingdom of Naples, however, still affords fine horses, especially for carriages; but they have, in general, large heads and thick necks: they are also untractable, consequently are difficult to be trained. These defects are, however, in some measure compensated by the largeness of their size, their spirit, and the beauty of their motions. They are excellent for parade, and very much affected stateliness.

The Danish horses are of such a large size, and so well set, that they were preferred to all others for coach horses: some are perfectly well-moulded, though in general their formation is not very regular; most of them having a thick neck, broad shoulders, the back a little too long and low; and the croup too contracted for the breadth of the chest; but they all move well, and are in general excellent for war and state. They are of all colours, even the most uncommon; the pyed and spotted being seldom seen but in Danish horses.

Germany affords some fine horses, but the generality are heavy and thick winded; though most of them come from Turkish and Barbary horses, of which there are many

studs; as also of Spanish and Indian horses: thus they make no figure in hunting and racing; whereas the horses of Hungary, Transylvania, &c. are very light and fleet: the Hussars and Hungarians slit their nostrils, with a view, it is said, to mend their wind, and, at the same time, to prevent their neighing in the field; it being affirmed that horses, whose nostrils have been slit, cannot neigh. It has not indeed been in my power to examine this particular; but it seems natural to think, that the operation can only weaken their neighing. The Hungarian, Croatian, and Polish horses are noted for having what is called the mark in all their fore teeth, which continues to old age.

The Dutch horses are very good for coaches, and are most commonly used in France. The best come from Friezland. The countries of Bergue and Juliers also breed very good ones. The Flemish horses are far inferior to those of Holland; they have generally large heads, broad feet, and their legs subject to dropical swellings. The two latter are capital faults in coach horses.

France produces horses of all kinds, but not many which may be called fine. The best saddle horses come from the Limosin, being something like the Barb, and excellent hunters, but of a slow growth. They must not be broke young, nor put to any service till they are eight years old. Auvergne, Poitou, and the territory of Morvant, in Burgundy, also produce very good ponies. But Normandy, next to Limosin, affords the finest horses; and if not such excellent hunters, they are preferable to the rest for war, are better set, and sooner trained. Lower Normandy and Cotentin, are famous for very fine coach horses: they are lighter, and more sprightly than the Dutch horses: Franche Comté and the Boulonnois furnish very good draught horses; but a general fault in the French horses, is the width of their shoulders; whereas those of the Barbs are too much contracted. *Buffon.*

Mr. Marshall, in his Rural Economy of Yorkshire, says, that "Yorkshire has long been celebrated for its horses. Fitzherbert, who wrote two hundred and fifty years ago, mentions his going to Rippon fair to buy colts.

"The influence of climature on the constitution, or changeable part of the nature of animals, is a matter difficult to be demonstrated. There are men who deny it. Nevertheless, strong evidences of its existence may be from the animal under consideration.

"No man has yet been able to breed Arabian horses in England; English horses in France or Germany; nor Yorkshire horses in any other district of England. Some good horses, no doubt, are bred every year in different parts of the kingdom; but they are few in proportion to the number of bad ones bred in those parts.

"In Norfolk, the breeding of saddle-horses has been repeatedly attempted without success. Yorkshire stallions have been, and still are sent into Norfolk in the covering-season. The foals may be handsome, but they lose their form as they grow up.

"On the contrary, in Yorkshire, let the foal when dropt be ever so unpromising, it will, if any true blood circulate in its veins, acquire fashion, strength, and activity, with its growth.

"This in my mind accounts fully for the superiority of Yorkshire-bred horses; and is a strong evidence that air, water, soil, or herbage, has an influence on the constitution or changeable nature of animals.

"The district more immediately under survey, may, perhaps, be considered as the first in the county for the breeding of horses. Nevertheless, it cannot even here be called an universal practice. Men are led into it by accident or caprice.

"It would be difficult to ascertain the exact number annually bred. The Vale, the Wolds, and Holderness, probably employ a hundred stallions. One hundred mares are considered as the full complement for one horse. Some of them, perhaps, do not get fifty. On this calculation, there are from five to ten thousand horses bred between the Eastern Morelands and the Humber.

"This calculation, however, is grounded on little more than supposition. It would be difficult to ascertain the exact number of stallions kept in so wide a district.

"It will now be necessary to consider separately, the breed; the method of breeding; and the management of worked horses in this district.

"Thirty years ago, strong saddle-horses, fit for the road only, were the principal breed of the Vale.

"During the last twenty years, some capital hunters have

have been bred in it. This change was principally effected by one horse, Jalap; a full-bred horse; whose pedigree and performances are well known upon the turf.

"He died in 1787; and, what is remarkable, at the age of thirty, covered several mares. His leap five guineas each, for blood mares; two guineas for "Chapmen's," mares."

"But notwithstanding the credit which the Vale has justly acquired of late by its hunters, the breed is at present changing to fashionable coach-horses; namely, tall, strong, over-sized hunters. The breed, therefore, may be said to have increased in size, rather than to have undergone a change. In 1783, the stallion-shows exhibited beautiful groups of animals, nimble as the greyhound, and spirited as the lion.

"There may be several reasons for the alteration which is taking place in the breed of horses in the Vale. The Jalapian breed has degenerated; very few of the sons of this celebrated horse have been good stock-getters. Another reason, and perhaps a better, is the unfitness of high-bred hunters for beasts of burden and draught. Not only brood mares, but growing horses, are used in husbandry. The operation of plowing with two horses requires strength. Slender horses are unfit for it; but a three or four year old coach-horse may be occasionally used; and, in cases of deformity or lameness, may be continued as a farm-horse. If to this be added, the extravagant prices which this description of coach-horses have recently borne, the Vale farmers may be right in propagating the breed.

"Be this as it may, they are most assuredly wrong, when they give encouragement to the Fen Breed, the "Howden mack" of black cart-horses, which I am sorry to see worming their way into the Vale. The breed of grey rats, with which this island has of late years been overrun, are not a greater pest than the breed of black fen horses: at least while cattle remain scarce, as they are at present; and while the flesh of horses remains to be rejected as an article of human food.

"Let the Vale-farmers continue to plow with coach-horses, and use oxen in carriage: a breed of horses better calculated for eating than working, and whose main tendency is to render their drivers as sluggish as themselves, are ill-adapted to the present rents of the Vale. Norfolk has already experienced the evil consequences of encouraging that breed; and I hope this country will not suffer by the same indiscretion. It is laughable enough to see a slender half-bred mare, who perhaps a few years ago, received the embraces of Jalap or his offspring, bending under the weight of a cumbersome animal, whose very legs, in all their admired roughness, are nearly equal in size to the body of her former gallant. No wonder that monsters, having not their likeness, in nature, should be the produce of such unnatural amours.

"From what has been said respecting the superiority of Yorkshire horses, it will no doubt, be expected that great attention is paid to breeding; and that the mysteries of it will be disclosed; while, perhaps, others have conceived that their superiority is more owing to the art of breeding than to the geniality of climate. I should be sorry if truth oblige me to discover the misjudgment of my readers; and feel myself awkwardly circumstanced in being under the necessity of disclosing the misconduct of my countrymen.

"In different parts of the kingdom the breeding of race-horses is reduced almost to science. In the Midland counties, the breeding of cart-horses is attended to with the same assiduity as that which has of late years been bestowed on cattle and sheep; while the breeding of saddle-horses, hunters, and coach-horses, is almost entirely neglected; is left almost wholly to chance: even in Yorkshire! I mean as to females. A breeder, here, would not give five guineas for the best brood mare in the kingdom; unless she could draw, or carry him occasionally to market; nor a guinea extraordinary for one which would do both. He would sooner breed from a rip which he happens to have upon his premises; though not worth a month's keep.

"But how absurd. The price of the leap, the keep of the mare, and the care and keep of her progeny, from the time they drop to the time of sale, is the same, whether they be sold from ten to fifteen, or from forty to fifty pounds each.

"Almost every thing depends upon the mare. There is an instance, in this neighbourhood, of the offspring of one mare being sold to dealers for four or five hundred

pounds. What are a few guineas in the first purchase of a good mare? and what are a few days plowing, or a few rides to market, compared with the difference between a race of good and of ordinary horses?

"It appears to me evidently, that much remains to be done in this department of Rural Economics. Good stallions may be had for money; and different hunts in the south of England will, so long as they remain, be a source of mares most suitable to the purpose of breeding capital hunters. Mares lamed or stiffened by severe exercise, and improper treatment, are generally to be bought in the neighbourhood of these hunts, at moderate prices. And mares fit for the breeding of coach-horses are to be met with in every county?"

"The present prices given for hunters and coach-horses, and more especially the declension of the breeding of the former, are incitements sufficient to induce men of spirit to make an attempt. Nothing appears to me to be wanting, but a Bakewell to take the lead.

"While the nation remains in its present state of refinement, horses for the road and the field are in a degree necessary; but racers and cart-horses might, with less inconvenience, be dispensed with.

"The king's plates have probably had their use in improving the English horse in activity and fleetness. But the original intention of them has long ago been answered: race-horses are now fit for the purpose of gamesters only. They are in general drawn much too fine for use. Therefore to continue these prizes will be distributing the nation's money toward the worst of purposes: the encouragement of gaming; and the injury of the breed of English horses. The broad-loined, deep-chested, old English hunter is giving place to the lank feeble racer. If it should be still thought proper to continue the king's plates, it would certainly be wise to raise the limited weight to twelve stone.

"With respect to cart-horses, if extending the saddle-horse tax to farm-horses in general would lessen their number, and increase that of working oxen, it would be political to extend it without loss of time.

"Under the present head it may be proper to register an idea which I have met with in this country; and which, evident as it may seem, never occurred to me before, either in theory or practice.

"It is a fact, well-established in the common practice of this district, that spayed heifers work better, and have in general more wind, than oxen; and it is not doubted that spayed mares would have an equal preference to geldings.

"I do not, however, find that the experiment has ever been tried. The reason held out against it, though formidable at first sight, proves a mere shadow on examination. The spaying of fillies would undoubtedly spoil them for brood-mares. But does not the gelding of a colt spoil him for a stallion? What breeder, when his mares foal, wishes for fillies? and what dealer would not willingly give half-a-crown a piece to have his mares changed into geldings? or perhaps into animals superior to geldings?

"In the spring of the year open mares are faint and troublesome. Nothing seems to be wanted but a safe cutter and a man of spirit to set him to work, to bring the spaying of female foals into common practice.

"It does not follow that, because a part of the female foals should be cut, there would not be open mares to breed from, any more than it does, that because some heifers are spayed for the yoke, or for fattening, there are not cows enough sufficient for the purposes of breeding and the dairy.

"I do not mean to recommend a practice of which I have had no experience; but if the experiment has not been tried, it strikes me forcibly that it is worth the trial; and that it is more than time it were set about.

"In a district where the working of oxen has been for many ages the established practice, it cannot be expected that any very accurate management of draught-horses can have taken place. But in a country which has always been considered as the source of good hunters, and the school of good horsemanship, it may be reasonably supposed that a superiority of management prevails.

"This, however, is not, from what I have seen, the case. The only striking feature of management which has caught my notice is, that of turning hunters and other hard-ridden horses out into the field in the day-time in winter; cold or warm, and sometimes wet or dry: a practice which has been cried up by many great horsemen, and is to be met with in every part of the kingdom; though no where so prevalently, perhaps, as in this country.

"It

"It has always struck me as a bad practice. Nevertheless, in compliance with the custom of the place I was in, I let a mare, which I rode into the country in 1782, run out to graze on leisure-days, and lie in the house at nights. The consequence was unfavourable, and sufficiently striking to induce me to minute the circumstances at the close of the occurrence.

"As the subject appears to be of considerable importance, I will here copy the minute.

"1783, *March 11*. There are perhaps few horses which will bear to be hunted one day and turned out to graze the next. My brother's practice is to let his horses run at graze in the middle of the day throughout winter. In conformity with this plan, mine was turned out in the day-time whenever I did not want to use her. On my arrival here in November last, though I had rode her a journey of two hundred miles, she was as fat as a mole, and her carcase round as a barrel. In the early part of winter I rode her a good deal, and shewed her the hounds generally once a week. With this exercise I was not surprised at her shrinking. But having more lately given her ease in order that she might recover her flesh and spirits, without finding any alteration, I had good reason to think that it was not altogether the work, but the treatment, which kept her down; for with all the indulgence I could give her, her sides, ten days ago, were clapped together, and her hide stuck as close to her ribs as if it had been glued to them. Her appetite for dry meat at least was gone. She would let her corn lie in the manger untouched; though for the time I have had her—six years—she has always been a remarkable good feeder. I had some blood taken from her, but she still remained the same. Suspecting that hanging after the graze was the only cause of her ill-thriving, she has for the last ten days been kept entirely in the house. Her skin is already loose and silky, and she calls for corn every time the stable-door is opened. The other day she wanted spurs; now she is all spirits again.—Turned out a mare, which he had hunted the day before, to graze, on a cold day. She got a violent cold; was seized of her limbs; and it has been with great difficulty he has saved her.—Began to turn out a valuable mare which he hunted occasionally; but finding that she refused her dry meat, he discontinued it; and now finds that she has taken to her hay and corn again. My brother's horse, used to it as he has been from his infancy, and pampered as he constantly is, looks more like a common hack than a hunter.

"There are two reasons why a horse which is subjected to violent exercise should not be exposed at graze, in severe weather. It takes them off their dry meat: and horses which sweat much are in the nature of things more chilly, suffer more from pinching cold, and are more liable to be seized by acute disorders, than horses which have more moderate exercise, and whose frames are less relaxed. A horse which has been enured to those transitions of heat and cold will, no doubt, bear them better than one which has always been used to a warm stable; and which certainly ought not to be exposed to such dangerous treatment without the greatest precaution.

"I am nevertheless of opinion, that letting a horse run out in winter keeps his legs cleaner and more supple than standing always in the stable. My mare was not fresher on her legs at four years old than she has been this winter. And if hunters could be turned out on leisure-days, when the weather is tolerably fine, into a spacious place to hay and corn, without graze, I am of opinion it would be of great service to them. Horses which are unavoidably exposed to transitions from heat to cold, as hunters frequently are, in sauntering by the side of a cover after a hard run, ought, indisputably, to stand in a cool stable, and to be exposed to the open air on leisure-days, so far as the state of perfect health and vigour will permit: but no farther."

"I make no comment on the foregoing facts and reflexions. I insert them as a caution to the inexperienced: and as hints to those who wish to hit the happy medium of treatment.

"I met with an idea in this district respecting the first turning out of a horse entirely to graze, which deserves to be generally known. When a horse is thrown up, or turned out at nights to graze, in the spring of the year, it is common to choose the forenoon of a fine day to do it in. The natural consequence is the horse fills his belly during the sun shine, and lays him down to rest in the cold of the night; thereby probably exposing himself to disorders.

A much better practice prevails here. The horse, instead of being turned out in the morning, is turned out at bed-time. The consequence is, he eats all night, and sleeps in the sunshine of the next day.

"It is generally understood here, that horses at graze do not require water. They are frequently kept for months together in dry upland pastures without water, and without any apparent inconvenience."

Though the most experienced horsemen are not always agreed in some points relating to shape, make, and goings of a horse, yet they almost always accord in this, that there ought to be a just proportion in all his parts. That even when he is taken to pieces, and examined singly in his particular members, though some defects may appear, yet when they all bear a just correspondence one to another, and concur in such a manner as to render his action easy, just, and regular, such a horse cannot be greatly disagreeable, but will, for the most part, move well, and with a tolerable good grace. On the other hand, suppose a horse has some parts exquisitely fine, and others indifferent, which frequently happens, it will mar his beauty, and cause him to look disagreeable, and for the most part affect his gait and action.

In order to have a horse beautiful and fine made, it has been agreed, on all hands, that his head should not be long, nor too large, rather lean than fleshy; his ears thin and narrow, and of a becoming length, well set on, pointing inwards; his brow or forehead not too broad and flat; his nose somewhat rising, and of a good turn; his nostrils wide and thin; his muzzle small; his mouth neither deep nor too shallow, with a star or snip down his forehead or blaze, which is no way unbecoming, unless it be too large and disproportioned.

Horses that are thus marked have generally one or more of their feet white, which is also very beautiful, and looks lively. His jaws should be thin and sufficiently wide, not approaching too near together, nor too high upwards towards the onset, that he may have sufficient room to carry his head easy, and in good place. His eyes well formed, sprightly, and of a middle size. His neck should be arched towards the middle, arising by a beautiful gradation out of his breast and shoulders, the muscles thereof distinct, but no where overcharged with flesh, growing smaller and thinner, as approaches towards his head. His shoulders should be thin from the withers, with a gradual enlargement downwards, that his bosom or breast be not too narrow nor too gross. His fore-legs straight and well placed; his joints lean and bony; his knees not bending, and his pasterns not too long; his feet round and smooth, and his sinews firm and well braced; his carcase rather round than flat; his back not too low, and for strength and durability pretty even and straight. His ribs rather home than open, as they approach towards his haunches; his buttocks round, and the muscles not too fleshy but distinct; his hocks or gambrels neither standing too wide, nor too near together; his hocks should be lean and no ways puffed or fleshy; his pasterns short, his legs flat and thin, and his tail set in a good place, rather high than low, rising upon every motion of his body. The more these properties concur in any horse, the more beautiful he must be, especially when they correspond and agree in due proportion, one to another; and the more a horse is wanting in these, the more plain and ordinary he will appear. See *CART-HORSE, and DRAUGHT-HORSE*.

HORSE-HOE, see the article CULTIVATOR and HOR.

HORSE-HOEING, the operation of cultivating plants according to the principles of the New Husbandry; viz. by hoeing the intervals or alleys between the rows of corn, and by that means supplying the plants with fresh nourishment.

"I have tried, says M. de Valliers, to hoe my alleys after M. de Chateaufieux's method, which I look upon as the best and most expeditious; notwithstanding that several difficulties which I have met with in the practice of it, have obliged me to give it up. For example, the great furrow in the middle of the alleys is, according to his directions, to be filled up by two turns of the plough, one on the right-hand, and the other on the left, after which it is to be opened again by one turn of the cultivator with two mould-boards, or two or three turns of the common plough.

"When I set about this work, the first turn of the plough, if the share went to any depth worth speaking of, always filled up the furrow in such manner, that to prevent it,

its being poached by the horses, I tried to make them walk on one side, upon the upper-ground, and consequently very near to the rows of corn: but then, in the first place, I could not avoid the destruction of a great number of plants, without giving such attention as was not only excessively troublesome, but almost impracticable: and secondly, I could plough only on the surface; because, as the furrow was filled, the plough could turn up but very little earth, without being choaked, and becoming extremely heavy.

"If, to save the plants, I made the horses tread partly upon the mould turned over into the furrow, the plough choaked equally, and for the same reason, whenever the furrow was cut deep. All I could do in this case, was to give only a superficial ploughing: and with that it was impossible to use the cultivator with two mould-boards, to form the furrow, because that instrument cannot work in any but a loose well-tilled ground.

"All these inconveniences may not happen in a soil different from mine. I am the more inclined to think this, as M. de Chateauxvieux certainly does not experience them: but at the same time I must likewise observe, that this justly celebrated gentleman has instruments so perfect, and directs his servants with such superior judgment, that few can expect easily to equal him in the practice of the New Husbandry.

"Not being able, for the above reasons, to do with one turn of the cultivator with two mould-boards, what, as M. de Chateauxvieux himself observes, can frequently not be done with less than three or four turns of the common plough, which, added to the two turns that are given to fill up the furrow, make in all five or six bouts; I pursued, and with great advantage, nearly the method before described. I say nearly that method, because I have made some few alterations, by which I think it is rendered both easier and better.

"1. I make the mould-board twelve or thirteen inches deep, instead of nine or ten that it was before. The furrows are by this means made wider, and the plough is more easily drawn, because it finds more room to discharge its load of earth in, and suffers less pressure.

"2. To give the second hoeing with the plough, instead of continuing to turn the earth over towards that side of the alley where only one furrow was turned up at the ending of the first ploughing, I, on the contrary begin this second at that furrow, approaching, if possible, to within two or three inches of the row of corn, and then I make a furrow in the contrary direction, which turns the earth up against that row.

"My reason for ploughing so near the rows, when I gave this second hoeing, is that I have observed that the rains which fall pretty frequently in the spring, between the first ploughing and the second, harden the earth greatly, and that drought afterwards hardens it still more, so that the roots of plants can no longer pierce or spread in it with ease; and yet nothing is more necessary, in order to their being benefited by every culture of the earth, than that they should find an easy passage into the mould, which lies next to the rows. It is therefore highly proper to stir that mould, when the second hoeing with the plough is given, which, with me, is when the corn has begun to spindle; that being the time when the plants shoot with the greatest vigour, and when their roots ought consequently to begin to extend to some distance.

"I have not perceived that the plants have been at all damaged by the plough's coming so near them. They ought to be so much the less hurt thereby, as the rows are placed over a furrow which has been cut deep; a situation which, alone, is capable of making the corn tiller, and push strongly: though the assistance of culture is likewise necessary, to supply the stalks and ears with plentiful nourishment.

"I am the better pleased with this method of bringing the hoe-plough almost close to the rows, as it facilitates a very important operation strongly recommended by M. Duhamel, and which I never before thought practicable: I mean, the raising up of the earth about the bottom of the plants; as well to give them greater nourishment, as to prevent their being lodged. The following is my method on this occasion.

"When I fill up the furrow which I have cut as close as possible to the row, I hold the plough sloping, in such manner that the earth is forced away from it, and is raised up about the plants. If this slope is not sufficient, which

may sometimes depend on the condition of the ground, or the dexterity of the ploughman, I, in that case, make the mould-board two or three inches wider, when I used to fill the furrow, than it was when I made that furrow: and to this end I screw on to the extremity of the mould-board, a thin plate of iron about four or five inches wide. Those who practise the New Husbandry in so extensive a manner as to employ several ploughs, will find no inconvenience in having one, larger than the rest, purposely for this important operation. As I do not give this second hoeing with the plough, till after the corn has begun to spindle, it is easy for me to avoid burying the plants, especially if there are no great clods in the ground: but, at all events I always earth the plants up as much as possible, when there is no other danger than that of burying here and there a few of them, because that accident is easily remedied afterwards, if it be worth while.

"When I am to give the third hoeing with the plough, I consider the condition of the ground. If it is in good tilth, well loosened, and free from weeds, I use only the cultivator: otherwise I use the plough, three or four turns of which are sufficient to perform this operation in the following manner:

"The first cut turns the earth over into the middle furrow: the second and third are on a contrary direction; and the fourth takes up what was loosened by the third, whereby the furrow is replaced in the middle of the alley. Some time after this, and especially if a shower of rain has fallen, I cut that furrow still deeper, by one turn of the single or double cultivator, as M. de Chateauxvieux directs.

"But as, even after all these ploughings, the great furrow may chance to be neither deep enough, nor sufficiently cleared of mould, owing either to the imperfection of the instrument made use of, or to the inaptitude of the ploughman, that defect may easily be remedied after harvest, by giving one ploughing more, which is to be begun by throwing up the earth to the right and left towards the summit of the beds; that is to say, over the stubble. This practice is also confirmed by M. de Chateauxvieux's instructions.

"The one ploughing extraordinary which this operation requires, ought not to be thought much of; because the most important point in the New Husbandry certainly is, the providing of a good depth of well-stirred mould, for the plants to extend their roots in."

The difficulty complained of by this gentleman, and some others abroad, in hoeing their crops, cultivated according to the New Husbandry, was occasioned, by their putting one or two wheels to their hoe-ploughs and cultivators. The hoe-plough should have no wheels; neither should any cultivators be substituted in the room of the hoe-plough. See the article CULTIVATOR.

HOT-BEDS, beds of earth enriched with manure, in order to forward vegetation, when the season or climate is not warm enough for the purpose.

By means of hot-beds, skilfully managed, the seeds of plants, brought from any country between the tropics, may be made to flourish even under the poles.

Heat and humidity being the great instruments of vegetation, to promote the growth of any plants, these must be duly proportioned, so as neither to exceed nor come short of the bounds nature has allotted for it.

The usual way of making hot-beds, is of horse litter and grass mixed together, and left on a heap for eight or ten days to putrify, and then removed into a bed, and covered up with glasses.

For raising cauliflowers, cucumbers, melons, radishes, and other tender plants and flowers in January or February, Mortimer directs to provide a warm place, defended from all the winds, by being inclosed with a pale or hedge of reeds or straw, about six or seven feet high. Within this raise a bed two or three feet high, and three feet over, of fresh horse dung, about seven or eight days old; then tread it down very hard, make it level, and, if you will edge it round with boards or brick, laying fine rich mould about three or four inches thick on it. When you find by your finger, that the extreme heat of the bed is over, plant your seeds at pleasure, and set your forks four or five inches above the bed, to support the frame, and cover with straw or mat, to secure the seeds and plants from cold and wet; only uncover them in a warm day, an hour before noon, and cover them again an hour after. Observe to earth up your plants, as they shoot up, and, when able to bear the cold, transplant them.

In Holland they use hot-beds made of sand; and likewise

wife of tanner's bark, which, when once rightly prepared, will maintain an equable heat for six months.

Bradley proposes very justly a thermometer to be used to regulate the heat of the hot-beds. Thus, a hot-bed for cucumbers must be kept so hot as to raise the spirit in a glass to the same height as the natural temperature of the weather will raise it about the end of May and June, when cucumbers will grow without artificial heat or shelter.

HOVEL, a shed open on the sides, and covered overhead.

HOVEN, a disease common to cattle, on eating too greedily of green clover. It consists in the paunch of the creature being swelled to a very great degree, which often, if not prevented, puts an end to the creature's life. The surest method of curing this terrible disease, is that of making an incision into the paunch of the beast, and by that means the wind, which caused the swelling, will escape through the orifice, and the creature recover.

A correspondent of the editors of the *Museum Rusticum* has given the following account of his performing this operation.

"I took, says he, a sharp-pointed pen-knife, and fixing my eye on the most prominent part of his belly, thrust the blade through the integuments quite into the abdomen: there issued out a great gust of wind very foetid, with some water of a reddish colour; the bullock seemed easier, but far from well; for the wound presently closed up, and admitted no more air to escape; so that I was under the necessity of stabbing him twice more in different parts of the belly before he was thoroughly relieved, which, by the help of a clyster after the last stab, was presently brought about: and here give me leave, gentlemen, before I leave this subject, to give a few cautions to those who may be under the necessity, one time or other, of performing this very useful operation: reflexion and experience warrant me in them; therefore I shall freely proceed.

"First then, if it be performed with a pen-knife, not to be fearful in pushing in the blade a proper length, till you find wind issue out; for if the wind be in the cavity of the belly, you cannot possibly hurt the gut, the whole body of the wind being between you and it, which no reasonable bladed pen-knife can touch; and if the wind should be pent up in the intestine, you must penetrate it before the beast can be relieved. To this last, perhaps, it may be objected, that we run the hazard of killing the beast by wounding the gut; but I am far from thinking so, as I have seen many wounds of the intestine, both in man and beast, very happily cured: yet granting there might be some danger in it, still we are certain, if the poor beast can get no relief, it must die; and so circumstanced, surely, a doubtful remedy is better than none at all.

"Another caution is, that where these wounds are made in the belly with a proper pen-knife, it is not advisable to have them sown up; for where there is a continual motion or action, as there is in the muscles of the belly and parts adjacent, such a practice is not only unwarrantable, but cruel; and why should we not behave with humanity to the brute species, as well as to any other.

"My last caution and advice is that upon all these occasions, when the beast is relieved of his wind, a proper clyster should be thrown up immediately, as hot as he can bear it: these clysters strangely relieve them, by acting as a warm comforting, bath to their distempered bowels, and emptying the same of the load of muck within them."

This account was sent by Mr. John Wynn Baker, near Dublin, to be published in the *Museum Rusticum* in the year 1764. Since that time Mr. Baker has made improvements upon the method of stabbing cattle, hosed, or swelled, by eating clover, or other grass, while it is very succulent; and moist with rain or dew, and which he has fully set forth in his report to the Dublin Society, for the year 1769, from whence the following is extracted.

"Farmers in general, are pretty well informed of the danger, to which horned cattle are liable, from their eating clover, by its hosing them. This unfortunate circumstance may deter many from the using clover, in the manner already mentioned. I am therefore to shew the means of avoiding the danger.

"And therefore, when they begin to use clover, it should be mowed two or three hours before giving it to the cattle. Begin the business in dry weather, and give it them sparingly in the commencement; a few days will ren-

der any further precautions unnecessary; because it may be mown and brought home immediately to fodder with, even when wet: until the second growth begins to be fit for cutting, and then a little caution will be again required, and that more particularly, if the weather be moist; and also when the clover is too short for mowing, it will be proper to be cautious in turning the cattle in to graze for a short time, in the beginning, and when no rain or dew is upon the clover; for it is the youth or softness of the clover, and rain or dew upon it, which are productive of the disease; when cattle, in their first feeding upon it, are allowed to eat too freely of it.—And it is very remarkable, that I tried some of my cattle with mown grass, and mown clover, and they rejected the grass for the clover; because I presume it is sweeter and more juicy; that juiciness is the very thing, as I conceive, which generates the air, to the great annoyance and infinite danger of the beast. These matters being attended to, the necessity of any further care ceases; unless upon a change of pasture, and then to clover again: in that case, I conceive the like precautions should be observed.

"I speak of these precautions from experience; for it may be remembered, that in the year 1764, I lost a bullock by his eating clover. And last summer, I had one bullock much diseased from the same cause; and also another bullock and cow, from their eating young lucerne; all from the carelessness and disobedience of servants; who imagine they know things and consequences better than any other person whatever. However, I happened to be at home upon both these occasions, and had the remedy in my own hand. I stabbed them all three, according to the method related in my report of the year 1764. A method so easy, now so familiar to me, and attended with so much safety, and speedy relief, that if I had five hundred head of cattle diseased in that way, I should not fear losing one by the operation.

"One of the plough bullocks, which I saved by stabbing last summer, was the very fellow that was in the cow's belly, which I saved in the year 1764, when she was diseased in the same manner, as related in my report for that year. And what seems to prove the inoffensiveness of this method of cure, namely stabbing; this bullock was stabbed about seven o'clock at night, and was ploughing all the next day, with as much unconcern, as if he had not been diseased or stabbed at all. And since finishing this report, I have stabbed this bullock twice in a fortnight, this summer, 1770, and we cannot tell the cause of his swelling. He is now very well, and was worked in the plough the day after being stabbed.

"With this knife (Plate XIX. fig. 7.) I stabbed the second bullock, which I had hosed last summer. Half an hour had not elapsed, before the boy who used to drive him in the plough, came running to me with the ploughman's phrase, who was helping to drive the bullock about, crying out, "Sir! Sir! the bullock is bursting!" I ran to him, not being at the time above twelve or twenty perches off, with the knife in my pocket. The man told me the bullock had fallen down, not being any longer able to move. Observing no wind to pass the wound, without hesitation I passed the knife into the same external orifice, and so into the paunch, or great receptacle of the intestines, when the quantity and impetuosity of the air was astonishing.

"The distress of the beast, at this second time of my seeing him, was truly pitiable. His tongue hung out of his mouth; his eyes full, as if they would have started out of his head; his rectum distended externally, at least five inches, and his hollow groans such as would move inhumanity itself.

"This second operation being necessary, requires some further explanation. We have seen, that although the bullock was stabbed, yet that he grew worse, inasmuch that a second operation was necessary. Looking at this consequence superficially, may induce one to imagine, that stabbing will not afford the expected relief. But it will as certainly do it, as wounding a blood vessel will be productive of the emission of blood. But as I conceive here is the cause. When the bullock came to move about, that motion had altered the position of the internal orifice, so that the air could not pass with the same rapidity, with which it rarefied internally, and when the bullock fell, (or laid down, I am rather willing to believe) the internal orifice was still more removed from its opposite position to the external one, and consequently no air could pass the wound: and therefore

therefore the disease must inevitably increase every minute with great rapidity, and thereby also contribute to moving the internal orifice farther from the external one.

"But the moment another puncture was made in the paunch, opposite the external one, we see the air rushed out, the beast got well, and was, I think, ploughing all the next day. Whereas, had not the second wound been given, I am persuaded he would have died in ten or fifteen minutes.

"In performing this operation, there is one circumstance which I must not omit to recommend to the attention of those who may have occasion to practise it: that they are careful not to enter the knife too near the hip-bone; which may be easily done by the deception which the flatulency excites, for the beast, when diseased, is so distended, that the operator may be deceived in the position of the hip-bone, not being so apparent as one would imagine. I therefore recommend the feeling for the short ribs, before the puncture is made; and they being found, pass the knife as near the center as may be, between them and the hip-bone.

"I mention this circumstance thus particularly; because, in stabbing the cow already mentioned, I made the wound too near the hip-bone, which I suppose wounded the vessels, and verge of the muscles adjoining to it; by which means the cow bled, I suppose not less than three or four ounces. Were that all it would be of no moment; but to the improper position of the wound, I attribute in some measure, the festering which ensued: whereas the bullocks did not bleed half a tea-spoonful: their wounds never festered; neither did they require any thing to be done to them, save that of rubbing on a little tar to keep off the flies.

"I was induced to invite the public, to see the remedy which I use, from hearing, that a great number of cattle are lost every year by the disease before us: as I hope thereby to diffuse the knowledge of so simple an operation through the kingdom. I am informed of a man in the county of Dublin, who lost seventeen fine cows in an hour last summer, by this disease; one with another worth seven pounds a cow. A poor woman in my neighbourhood had but two in the world; I am told she lost them both in half an hour, by their slipping into a gentleman's clover; and I hear of several cattle lost this summer.

"The bullock stabbed as above-mentioned (he being a strong beast) gave me a kick, which knocked me down, and rendered me incapable of standing for some time. That other people may not meet with the like accident, I recommend to them, that they stand with their left side close to the left shoulder of the beast to be relieved, laying the left hand upon the back of the animal, and with the right hand perform the operation, in the part, and with the knife disposed as described above. A pen-knife is too small.

"From A (Plate XIX. fig. 7.) to the point, the knife is as sharp as a lancet. From A to B, the flank gradually swells, and does not cut at all, but has a round edge on each side, that it may not cut, in with-drawing the instrument.

"C C, into, or upon the shoulder of the handle, screws an hollow socket or case; that, and the handle both of lignum vitæ. The handle five inches long.

"The blade is also five inches long, and when used, is sent quite home to the hilt."

Mr. Marshall, in his Minutes of Agriculture, recommends salt and water, or strong brine, and exercise of running, of service in relieving cattle that are hoven or sprung as it is sometimes called. He tried the experiment on a cow that had eaten too heartily of cabbages. The dose was three or four handfuls of salt to about three pints of water. This was given three times, to the last was added half an ounce of pepper.

HOUGH of a horse, is the ply or bending of the hind legs, and likewise comprehends the point behind, and opposite to the ply, called the hock.

The hams of a horse should be large, full, and not much bended; as also discharged of flesh, nervous, supple, and dry, otherwise they will be subject to many imperfections.

HOVER GROUND, light ground.

HOUSE-BOTE, an allowance of timber out of the lord's woods, for the repairs of a house.

HULLS, the chaff, or husks of corn.

HURDLES, are certain frames made either of split

timber, or of hazel-rods, wattled together, to serve for gates in inclosures, or to make sheep-folds, &c.

HURDS, or *Hords* of flax or hemp, the coarser parts separated in the dressings from the tear of fine stuff.

HURLE-BONE, in a horse, a bone near the middle of the buttock, very apt to go out of its socket with a hurt or strain.

HUSBANDRY, the business or employment of a farmer, or person who cultivates land, &c.

Husbandry is divided into two kinds, and distinguished by the epithets Old and New. The former is that which has been practised in all countries from the most early times; and the latter that introduced by the ingenious Mr. Tull, and often called the horse-hoeing husbandry.

Experience shews, that land though ever so well tilled in the autumn, when wheat, for example, is sown, hardens and soddens in the winter; its particles, beaten down by heavy rains, and sunk by their own weight, approach each other daily more and more; the roots of the plants cultivated have consequently less and less room to extend themselves in quest of their necessary food: and their interstices in the earth become of course so few and close, that they are not able to pierce through them, whilst weeds spring up, and rob them of their nourishment. By this means the earth, reduced to nearly the same condition as if it had not been ploughed at all, is unable to assist the plants sown in it, in the spring, when they ought to shoot with the greatest vigour. They consequently then stand most of all in need of the plough to destroy the weeds, to lay fresh earth to their roots in the room of that earth which they have exhausted, to break the particles of the ground anew, so as to enable their roots to spread, in order to their gathering an ample provision of food, which then does them the greatest service.

In the common husbandry, the whole attention is to provide a great store of nourishment for the wheat, at a time when it scarcely consumes any, as it then produces only a few blades, after which it is left to itself, at a season when it might, and should be most assisted by proper culture; a management as preposterous as it would be to give a child a great deal of food, and diminish it gradually as he grows bigger; or, to use Mr. Tull's comparison, to give silk-worms, before they are hatched, treble the full stock of leaves necessary to maintain them, till they have finished their spinning, and not to allow them any when they really want being fed.

The great advantage of having land in fine tilth before it is sowed, is universally acknowledged: but we must not stop at those first preparations. Plants require a continuation of culture while they grow, and must not be forsaken till they have attained their full maturity.

Those who are against the frequent ploughings used in the New Husbandry, are afraid of drying the earth too much; because, say they, the moisture escapes more easily from a well loosened soil, than from a hard and close earth.

In answer to this it will appear from many of the following experiments, that, even in the driest weather, land cultivated according to the new method, continues constantly moister than that which is managed in the old way. Instead of a stagnant wet, more hurtful, perhaps, than beneficial, to plants; earth made fine to a good depth, is prepared, as the reverend Dr. Elliot expresses it, "with open mouth, to drink and retain the dew, which, when it falls upon the land that is untilled, or but poorly tilled, does not sink far, but is carried off by the next sun's heat." That dew is one of the greatest fertilizers of the earth, has been repeatedly proved; and that it will penetrate so deep in a fine loose soil, as to keep that moist, while the ground badly tilled is parched up, appears, among many demonstrations, from Mr. Evelyn's experiment of digging a hole, and filling it up with its former mould well pulverized; or as Mr. Tull observes, till a field in lands; make one land very fine by frequent deep ploughings, and let another be rough, by insufficient tillage, alternately: then plough the whole field cross-wise in the driest weather, which has continued long; and you will perceive, by the colour of the earth, that every fine land will be turned up moist; but every rough land will be as dry as powder, from top to bottom.

Another proof of the benefits which arise from stirring the ground well and often between plants while they grow, and consequently a confirmation of the fundamental principle of the horse-hoeing husbandry, is thus drawn by Dr.

Dr. Elliot, from the common manner of raising Indian corn.

"The land, says he, being previously prepared, planted, and the corn come up, we plough a furrow off from the corn on each side, then hoe it, and the next time plough up to the corn; so that this tillage is nearly the same as is now proposed for wheat, or whatever we would plant: only by the way, I would observe, that the ploughings between the rows, for Indian corn, is so shallow, that one would be apt to think it intended for nothing more than merely to kill the grass and weeds; whereas it is found by experience, that, though there be neither grass nor weeds, the ploughing and hoeing will make the corn grow, and that the more the land is ploughed and hoed, the better and longer it will resist drought, and yield the better crop: nay, what is still more remarkable, if the Indian corn be well tilled, the next crop, whether it be oats or flax, will be proportionably greater and better; so that the land must have gained strength and richness. If it were not so, why did not the Indian crop exhaust and spend the strength of the land, especially when we consider how large that corn is made to grow by good tillage? but we find the contrary; the better the crop of Indian corn, the better the crop will be of oats. There is no sort of husbandry, wherein the superior force and virtue of tillage doth so evidently appear, as in the raising of Indian corn: for if you should plough and harrow the best of land, and sow or plant the corn, and never do any thing more to it, there will be less corn than if you should plant poor land, and tend it well: the poor land well ploughed and hoed, shall bring a greater crop than the rich land. We hereby see the efficacy and advantage of this repeated tillage, which falls in successively, according to the exigency and want of the plant in its several degrees of growth, and keeps the land in a proper state. Why should it not have the same effect upon wheat, and every other plant that is susceptible of the like culture?"

If several rows of wheat are sown in a poor but well ploughed land, the blades of the corn will turn yellow in the spring, especially in dry weather. Let the earth bordering upon these rows be ploughed deep, in some places near, and in others farther from the rows, and the plants will resume their proper colour; first in the places nearest to the new ploughed ground, and afterwards gradually in the others, according to their distance; which proves that they recover their verdure, in proportion as their roots reach the loose mould. This holds equally true in all plants; for Mr. Tull declares, that he does not remember ever to have seen a poor one contiguous to a well-hoed interval, unless overpowered by a too great multitude of other plants, an exception which must be equally made if it were a plant that required more or less heat or moisture than the soil or climate afforded; and that, on the contrary, he has seen plants grow to an amazing size, when the earth around them has been frequently tilled. He mentions, among others, a plant of ray-grass, which chanced to stand in a turnep field, where, being hoed as the turneps were, it acquired a bulk at least equal to a thousand plants of the same species; and a plant of mustard, which grew higher than he could reach, so as to be more like a tree than an herb.

The stirring of the earth about the plants whilst they grow, is productive of such excellent effects, that, in some parts of Berkshire, and in many places in France, they hand-hoe their corn, particularly wheat, and find that the crops amply repay all the charge and trouble of this expensive operation: which, however, cannot be performed but in well-peopled countries. Every husbandman will immediately see, how much a hoe-plough is preferable for this work, and that, to use it rightly, the corn must necessarily be planted in regular rows, as it is in the New Husbandry.

Our reason tells us, that the longest lived plants stand most in need of this culture. Perennials require it more than annuals, and wheat which is sown in autumn, and does not ripen till nine months after, want it more than spring-corn, which occupies the ground only for a few months. The former has to conquer a soil rendered hard during the course of the winter; but the other has not that difficulty to surmount, though both of them, and indeed all sorts of plants, are greatly invigorated by the repeated laying of fine fresh earth to their roots. Every one knows the vast efficacy of wood-land, before its native strength and vigour are exhausted; and such, in some de-

gree, is that which this tillage furnishes; besides being constantly attended with the advantage of destroying weeds. How far this last important part of agriculture was well executed by the sarcling, or sarrition, as Mr. Tull calls it, of the ancients, we shall not pretend to say, because we have no clear account of the manner in which it was performed; but it does not seem to have been in any way equal to the horse-hoeing husbandry, which likewise, among its many other excellencies, keeps the land from going out of tilth.

We shall here add M. Duhamel's observations on the use of dung, as given by that gentleman in his *Elements of Agriculture*.

"It is often, says he, more advantageous to increase the fertility of land by ploughing, than by dung: 1. Because, in general, only a certain quantity of dung can be had, the product of twenty acres being scarcely sufficient to produce enough for four or five; whereas the particles of the earth may be divided and subdivided almost to infinity. The help derived from dung is therefore limited; whilst no bounds can be set to the benefits that may accrue from ploughing.

"2. Few plants raised in dung ever have the fine flavour of those which grow in a good soil moderately dunged. Our kitchen gardens and our other grounds afford daily instances of this truth. Pulse, pot-herbs, and fruit, are seldom so good in the neighbourhood of great cities, where dung abounds, as in country gardens, where but little of it is used. The corn raised in those excessively dunged lands, yields a great deal of bran, and not much fine flour, and is difficult to keep. Nice horses will not eat oats of the growth of fields manured with human ordure. But nothing is so striking as the difference between the wine of an undunged vineyard, and that of vines which have been greatly dunged.

"3. Dung, which is supposed to act by fermentation, causes indeed an inward division of the particles of the earth, which must be very useful, as well as the food which it furnishes to plants: but the plough, besides dividing those particles, changes their situation, and turns the ground upside down, so that the part which was exposed to the influences of the air and dews, takes the place of another part which is brought from within the earth, up to its surface. The consequence of this is, that well ploughed land is not exhausted by weeds, and that it admits the moisture of rains and dews, together with the rays of the sun, all of which contribute greatly to render it fertile, as has been proved by very many experiments.

"4. Dung attracts insects, and those insects gnaw plants. It is well known that the roots of trees planted in dunged ground, are very liable to be damaged by insects: and this is one of the chief reasons why florists banish dung from their gardens. Worms, grubs, and other such like vermin, make dreadful havock in their beds of flowers; and I have seen meadows where the grass has been entirely destroyed, by their eating its roots.

"I must add, that most sorts of dung contain a great many seeds which fill the land with weeds.

"5. It is true that dung is equally serviceable to light lands, and to strong; but the same may be said of ploughing.

"Land is too strong when its particles lie so close together, that the roots of plants cannot extend between them, without great difficulty in quest of their necessary food; for want of which they will remain poor and sickly: but when the ground has been well loosened by repeated ploughings, and its plants are set at greater distances from each other, those roots will be able to spread freely on all sides, to pervade every minute chasm, and to collect such quantities of food as will make the plants grow strong and vigorous. The friendly influences of the atmosphere will then penetrate to them. What plainly proves the good effects of loosening such soils, is, that their fertility is sometimes increased by a mixture of sand, instead of dung. Now sand does not afford any nutritive substance; but only hinders the particles of the earth from re-uniting too closely.

"Ploughing is equally beneficial to light lands, for the very contrary reason; though these do not require so much of it as the other. There is no danger of their being exhausted by any exposure to the sun; but, on the contrary, they acquire an additional degree of fertility by the stirring, and grinding of their particles, and are thereby the better fitted to receive the moisture of rains and dews, and the salutary

salutary influences of the air and sun; whilst their inward pores are at the same time better adapted to the proper extensions of the roots of plants, by their being lessened.

"But let the benefits arising from dung be ever so great, let the means of obtaining enough of it be ever so easy, and let even its defects be corrected as much as can be, still it will not be the less true, that frequent ploughing is of infinite service to land.

"For this reason it is, that land intended for wheat is ploughed three or four times before the grain is sowed. Some farmers, who could not dung all their lands, ploughed part of them double the usual number of times, and reaped greater crops from these, than from those which were dunged. The expence of the ploughings extraordinary will be much less than the price of the dung necessary for the land, if the farmer is obliged to purchase it.

"In 1759, M. Delu gave three ploughings to some of his fields intended for oats; and though that year was very dry and unfavourable to spring corn, his oats kept up well till they were perfectly ripe, and yielded a full crop of excellent grain.

"He gave five ploughings to a piece of wheat-land which had not been dunged, and at harvest, had taller and finer corn there, than in the neighbourings grounds which had been dunged and cultivated in the usual way. In short, the advantage of thorough tillage, while the plants are growing, is so great, that, in many places, it has been found amply to repay even the expence of digging between the rows of corn.

"The farmer must not think of practising the New Husbandry in land which cannot be brought to a fine tilth: for as no remedies are proper for all diseases, so no one culture can suit every kind of soil.

"I have met with very zealous husbandmen, who have been in a great hurry to procure all the instruments proper for the horse-hoeing husbandry, before they had examined whether their ground was fit for using them. In walking over the fields, I have found them in so bad order as to be full of clods, stones, and all sorts of weeds: only the bare surface of the land had been scratched, by what they called ploughing; and indeed their common instruments of tillage were so imperfect, that it was hardly possible for them to do more. I advised them to destroy those weeds by good and frequent ploughings, to procure good instruments, to loosen the ground to a proper depth, to collect good manures, to drain their land well by trenches and ditches, and, in short, to practise the Old Husbandry completely, before they attempted the New; for, in fact, all the requisites in the former must be the foundation of the latter.

"To answer the ends of this husbandry, the seeds must be distributed so sparingly, that each plant may have room to extend its roots in such manner, that they may be able to collect an abundant quantity of food; each plant must be enabled to tiller greatly, so as to produce a considerable number of stalks; and each stalk must be enabled to bear a fine long ear, well filled with grains to its very point.

"To effect the first of these qualities, the field, after being thoroughly ploughed and well harrowed, must be divided by furrows, the spaces between which may be of such breadth as shall be judged most proper; for neither their precise width, nor the distance between the rows of corn, is yet fully determined. In the middle of these spaces, which will be distinguished by the name of beds, the wheat, or other grain, is to be sown in one, two, or more rows. An inch will be sufficient for the distance between the grains, lengthwise of the row; though that may be somewhat less, if the ground be not very good for wheat; or, on the contrary, somewhat more, if it be excellent for that grain. By this distribution, each plant will find, in the intermediate spaces between the beds, and in the beds themselves, a sufficient extent of earth wherein to collect its necessary food; for those intermediate spaces, which I shall call alleys, must be wide enough to admit of stirring the ground in them while the plants grow: but to answer the second and third intentions, it is of consequence that these stirrings be performed at proper seasons, because each of them is to produce its particular effect.

"It is essentially necessary that the rows of corn be sown very straight; a circumstance which, though it be attended with some trouble, ought not to discourage the husbandman, because the great difficulty will be only the first time. After the ground has been once rightly sown, it will be

easy to continue in the same regular tract every following year, without taking the precautions I am now going to observe.

"If the field be not very large, a furrow traced with a spade or pickaxe, directed by a line stretched across the ground, will enable the ploughman to guide the horse that draws the drill; and he will take care to leave a proper interval between one furrow and another, if three rows are to be sown.

"If the extent of ground be too great for the above method, poles or stakes may be stuck, five feet asunder, at each end of the field, to guide the ploughman, who, with a common plough, will trace small furrows, by the help of which the horse and drill may be properly directed.

It will be right, if possible, to suit the direction of the furrows to the declivity of the land, that the water may drain down to the lowest part of the field, where a ditch should be dug to carry it off: and it will also be necessary, to make them lengthwise of the field, if convenient, that the less ground may be lost by the space which must be left for the plough to turn in.

"After the seed is put into the hoppers of the drill, the horse which draws this instrument must be made to walk slowly in the furrow before traced by way of guide: and in order to drop as nearly as possible the intended quantity of seed, the outlet of the hopper must be proportioned to the size of the grain.

"As it will be somewhat difficult to manage the drill rightly at first, till the husbandman becomes used to it, he should look over his field as soon as the corn has sprouted, and then drop by hand a few grains in the place where it may have failed.

"The land should be sown about the middle of September, or, at farthest, by the end of that month: and it will be right always to try the goodness of the seed beforehand, by sowing fifty or an hundred grains of it in a fine mould, or moist ground, where it will soon appear whether they all rise.

"Land which retains water should be ploughed once in October, when the weather is fine. In doing this, a furrow should be first cut in the middle of the alleys, and then it should be filled with the earth on each side, even so far as to arch it up, and leave only a small furrow on either side, close to the beds, to drain off the wet, which would prove very prejudicial to the plants if it were to remain long near their roots. This loosening of the earth will also fit it for being mellowed by the winter's frosts; to which, however, care must be taken not to expose the roots of the corn, by leaving them too bare of mould. The most proper time for this stirring of the ground is when the plants have shot out some blades.

The second horse-hoeing, which should be given as soon as the hard frosts are past, that is to say, by the end of March, is intended to make the plants tiller; and will have this effect, if, after the earth near the rows has been stirred a little, that which was before laid up in the middle of the alleys be returned back to the furrows at their sides. This earth, having been mellowed during the winter, will afford excellent nourishment to the plants, now beginning to vegetate apace, and they will soon put forth their multiplied stalks.

"The third hoeing, which is the second after winter, and is intended to strengthen the stalks, should be performed when the ears of the corn begin to appear. This culture, which is looked upon as the least important of all, and is sometimes even omitted without any great inconvenience, need not be any thing more than a slight stirring of the earth, in which it will however be right to begin to hollow the alleys.

"The last stirring of the earth between the rows of corn is one of the most important, being that which makes the grains swell, and grow full-bodied to the very point of the ear. The most proper time for this is, when the ears begin to bloom: but as the corn is then high, only one furrow can be cut in the middle of the alleys, the earth of which should be laid up to the stem of the plants on each side. The plough will hardly be able to pass more than twice in this furrow, which should, however, be made as deep as possible, in order to bank up the greater quantity of earth. By this operation, the now fallow alleys are prepared for the next sowing; for it is in the middle of them that the corn is to be planted the following year; and the now eared wheat is earthed up, to prevent its being lodged; though in general corn thus cultivated is less apt to be

beaten down, than that which is raised in the common way, because the straw of this being more exposed to the air, becomes harder and acquires a firmer texture, especially toward its bottom. It is for this reason that a tuft of corn, which stands quite single, is scarcely ever beaten down by the weather.

"These repeated hoeings of the earth will certainly be rewarded with a very plentiful crop, unless the seasons prove extremely bad.

"When the corn is reaped, all possible care should be taken not to trample upon the adjoining ploughed ground.

"It is well known, that vigorous plants do not ripen their seeds so soon as those which have been stunted in their growth: for this reason the corn cultivated according to the principles of the New Husbandry, ripens later than in the common way, and should therefore be sown somewhat earlier.

"We will now suppose that the crop is reaped, and that the same field is to be sown again with wheat the next year, and every year after, as it may be, because the rows of corn are placed each time in the middle of the former alleys, which have been ploughed during the whole year, without producing any thing. Thus, the only difference between this new method and the old husbandry, is, that instead of resting, or fallowing, a whole field, whilst another whole field is under corn, and each of them is separate from the other, the fallow here is in the same field as the corn, being interposed by means of alleys, which is the part rested between the beds, and is the part cultivated: but there is this great advantage here, that the stirring of the earth in the alleys, which are not planted, not only prepares the soil admirably for being sown the next year, but invigorates the plants actually growing in the beds.

"If it be thought proper to dung the alleys, in order to prepare them for the reception of the seed, the dung, which should be thoroughly rotten, must be laid in the bottom of the deep furrow before made in the middle of them, and there covered with the earth which was thrown up towards the rows of wheat. If the land does not want dunging, this deep furrow is filled up without it; and this should be done immediately after harvest, that there may be time to give the ground another stirring, which need only be a slight one, before the sowing of the rows, which are now to be in the middle of the former alleys; and the alleys of this year will be in the place of the last year's stubble.

"Though land, cultivated according to the principles of the New Husbandry, does not require so much dunging as that which is managed in the old way, yet this manure will always help to enrich the soil, especially if it be used in the manner here directed. By being thoroughly rotten when it is laid in the furrow, and there covered over immediately after harvest, it will have time to mellow and diffuse its influence, and not be apt afterwards to choke up the shares of the drill; an inconvenience which does not happen with pigeons dung, which therefore need not be strewed till the ground is ploughed for sowing.

"It is farther observed,

"1. That if dung be used for the second year's crop, very little of it will suffice, because it need only be laid in the bottom of the furrows.

"2. That there can hardly be any occasion for dung this second year, because, if the earth of the beds in which the wheat grew was good, that of the alleys, of the same soil must be still better, by reason of its having been fallowed and well tilled.

"3. That the second year's wheat is placed in a most advantageous situation, its roots having a depth of twelve or fifteen inches to extend themselves in, by means of the furrows which was in the middle of the alley. For this reason, corn ought to thrive best in those lands which have been longest cultivated according to the New Husbandry.

"The earth in the alleys is to be horse-hoed during the second year, in the same manner, and at the same seasons, as in the first.

"This frequency of hoeing ought not to be objected to; for the labour of the first hoeing, to make the furrows on each side of the rows, and lay the earth up in the middle of the alleys, cannot be great; and the second only returns that earth into those furrows: the third is only to stir the surface of the soil: the fourth and last is to make the deep furrow in the middle of the alleys, and bank up the rows of corn on each side, with the earth taken out

of it; so that neither of these operations ever extends to above a third part of the ground, at any one time.

"The whole field might indeed be ploughed up after harvest: but I would advise the husbandman not to touch the stubble then, because the rows of that will help him to guide the drill in straight lines, and the yet unrotten straw might be apt to clog the shares of the drill, so as prevent their working properly. However, if the stubble be very short, this caution becomes the less material, and the whole field may then be ploughed; though still it will be necessary to plough it again in October, in order to make drains to carry off the wet.

"It is almost needless to observe, that all the operations of which I have been speaking, must often be performed either a little earlier, or somewhat later, according as the year is more or less forward; and that it will always be necessary to wait till the ground is dry enough to be ploughed without danger of its clodding; a circumstance which varies greatly, according to the nature of the soil."

Mr. Young, in his *Annals of Agriculture*, observes, that "the common husbandry about Faversham is generally in the round tilth; that is to say, 1. barley; 2. beans; 3. wheat; which is the famous rotation of East Kent. They put in their beans with a drill-plough, of a very simple construction, on the rolling principle; ten rows in a rod, or between eighteen and twenty inches distant; keep them in a garden degree of cleanness, by horse and hand-hoeing, the latter generally twice or thrice, and two, three, and four horse-hoeings; they use a shim, which they call a horse-break, for cutting the weeds and loosing the surface of the intervals; earth them up twice, first with a moveable iron fixed to the break, and afterwards with a double mould-board plough, made on purpose, with a very long round share, finishing in a narrow point. They work the last tool with a horse among the beans, even when they are in full blossom, and find that they receive no damage from it. After harvest they cut the stubble with a shim two feet wide, which answers the purpose of the great stile of Thanet shim for preparing the land for ploughing. Their crops of beans are very considerable, rising to six quarters an acre; the wheat which follows is generally great; what I saw I should guess at four quarters; five are sometimes known, but not often; in general about three and a half or four quarters; the earliest sown, universally the best; they have an idea of barley which is very singular, that it is exceeding favourable to the land; they sow it late, which gives such an opportunity of tillage, that they are decidedly of opinion that it leaves the land cleaner than beans, yet they esteem beans the best preparation in the world that wheat can receive. The lateness of their barley season, I should apprehend, must be prejudicial to the crop; for, upon land of Mr. Firmstone's at the Abbey farm, the barley crops were not comparable to what I had seen in crossing Essex, nor even equal to what I had left upon my own farm, on soils not to be named in the same day with these. This rotation is in the teeth of a maxim, which the more I see the more I am convinced is just, that no two crops of white corn ought ever to come together; this round tilth, upon land inferior to the Kentish, would presently run it out of heart; for that barley exhausts infinitely more than beans, and that it fouls land more, would be proved by such an experiment as this; let one half of a field be under barley, and the other under beans, then sow the whole with wheat, which I may very safely pronounce would be twice as good after the beans as after the barley.

They put all their manure on beans, a most unexceptionable practice. They sometimes follow this course, 1. beans: 2. wheat; and continue it till the land is foul; but then, pursuant to the above ideas, throw in barley to clean it."

The editors of the last edition of Mr. Tull's *Horse-hoeing Husbandry*, give, in their preface to that work, the following comparative calculation of the expence and profit of the old method of culture and the new, drawn up by a gentleman who has practised both some years, and who has no attachment to the New Husbandry, farther than he has found it answer in his trials. They candidly appeal to experience, "whether every article in this calculation is not estimated in favour of the common husbandry; whether the expence be not rated lower than most farmers find it; and whether the crop be not such as they would rejoice to see, but seldom do.

"In the New Husbandry, every article is put at its full value,

value, and the crop of each year is computed four bushels short of the other, though, in several years experience, it has equalled, and generally exceeded, those of the neighbourhood in the old way.

An Estimate of the Expence and Profit of Ten Acres of Land, in Twenty Years.

I. In the Old Way.

First year for wheat cost 33l. 5s. viz.	1.	s.	d.	1.	s.	d.
First ploughing at 6s. per acre	3	0	0			
Second and third ditto, at 8s. per acre	4	0	0			
Manure, 30s. per acre	15	0	0	22	0	0
Two harrowings and sowings, at 2s. 6d. per acre	1	5	0			
Seed, three bushels per acre, at 4s. per bushel	6	0	0			
Weeding, at 2s. per acre	1	0	0			
Reaping, binding, and carrying in, at 6s. per acre	3	0	0	11	5	0
Second year for barley costs 11l. 6s. 8d.						
Once ploughing, at 6s. per acre	3	0	0			
Harrowing and sowing, at 1s. 6d. per acre	0	15	0			
Seed, four bushels per acre, at 2s.	4	0	0			
Weeding, at 1s. per acre	0	10	0			
Cutting, raking, and carrying, at 3s. 2d. per acre	1	11	8			
Grass-seeds, at 3s. per acre	1	10	0	11	6	8
				44	11	8
Third and fourth years lying in grass cost nothing. So that the expence of ten acres four years comes to 44l. 11s. 8d. and in in twenty years to				222	18	4
First year's produce is half a load of wheat per acre, at 7l. per acre	35	0	0			
Second year's produce is two quarters of barley per acre, at 1l. per acre	20	0	0			
Third and fourth year's grass is valued at 1l. 10s. per acre	15	0	0			
So that the produce of ten acres in four years is	70	0	0			
And in twenty years will be	350	0	0			
Deduct the expences	222	18	4			
And there remains clear profit on ten acres in twenty years by the old way	127	1	8			

II. In the New Way.

First year's extraordinary expence is	1.	s.	d.
For ploughing and manuring the land, the same as in the old way	22	0	0
Ploughing once more, at 4s per acre	2	0	0
Seed, nine gallons per acre, at 4s. per bushel	2	5	0
Drilling, at 7d. per acre	0	5	10
Hand-hoeing and weeding, at 2s. 6d. per acre	1	5	0
Horse-hoeing six times at 10s. per acre	5	0	0
Reaping binding, and carrying in, at 6s. per acre	3	0	0
The standing annual charge on ten acres is	13	15	10
Therefore the expence on ten acres in twenty years is	275	16	8
Add the extraordinaries of the first year and the sum is	297	16	8
The yearly produce is at least two quarters of wheat per acre, at 1s. 8d. per quarter, which on ten acres in twenty years amounts to	560	0	0
Therefore, all things paid, there remains clear profit on ten acres in twenty years, by the new way	262	3	4

"So that the profit on ten acres of land in twenty years, in the new way, exceeds that in the old by one hundred and thirty-five pounds one shilling and eight-pence, and consequently is considerably more than double thereof; an ample encouragement to practise a method whereby so great advantage will arise from so small a quantity of land, in the compass of twenty-one years lease; one year being allowed, both in the old and new way, of preparing the ground.

"It ought withal to be observed, that Mr. Tull's husbandry requires no manure at all, though we have here, to prevent objections, allowed the charge thereof for the first year; and moreover, that though the crop of wheat from the drill-plough is here put only at two quarters on an acre, yet Mr. Tull himself, by actual experiment and measure, found the produce of his drilled wheat-crop amount to almost four quarters on an acre; and, as he has delivered this fact upon his own knowledge, so there is no reason to doubt of his veracity, which has never yet been called in question. But that we might not be supposed to have any prejudice in favour of his scheme, we have chosen to take the calculations of others, rather than his, having no other view in what we have said, than to promote the cause of truth, and the public welfare."

A comparative Calculation of Expence and Profit between the Drill and the Common Husbandry, taken from Mr. Baker's Report to the Dublin Society of his Experiments in Agriculture, for the Year 1765. Published by Order of that Society.

*An Estimate of Expence upon a Plantation * Acre of Wheat, in the Common Husbandry.*

To the first ploughing, commonly called breaking for fallow, 8 horses, 8s. 2 ploughmen, 1s. 4d. 2 drivers, 1s.	1.	s.	d.
	0	10	4
To the first harrowing, 4 horses, 4s. a driver, 6d.	0	4	6
To the second ploughing, commonly called gaurowing	0	10	4
To the second harrowing	0	4	6
To the third ploughing, commonly called stretching	0	10	4
To sowing the seed, 8 horses, 8s. 2 ploughmen, 1s. 4d. 2 drivers, 1s. the seed-man, 8d.	0	11	0
To seed wheat, one barrel	1	0	0
To rent for the year of fallow	0	18	0
To ditto, the year the crop is growing	0	18	0
	5	7	0

In this account 40s. are charged for 40 horses, employed in the culture of one acre for wheat, in the common husbandry; a charge which ought to be considered by the farmer; for he actually buys and maintains his horses for this business.

The crop which follows wheat is generally oats; but sometimes pease are sown instead of oats; with some, the practice is to let the pease follow oats; in which case they fallow only every fourth year; but where land receives no other assistance than what arises from fallow, it is a bad practice not to fallow every third year. It is the general practice to plough but once for oats; and therefore it shall be stated so; but it is a much better practice to plough the wheat-stubble once before winter, and again in the spring.

An estimate of expence upon an acre or oats.

To ploughing once	1.	s.	d.
To seed oats, 2 barrels	0	10	4
To harrowing, 4s. 6d. seed-man, 4d.	0	12	0
To one year's rent	0	4	10
	0	18	0
	2	5	2

These two crops consume three years; after which the farmer is to begin again, and to incur every article of expence stated in the above accounts, in order to obtain two crops more.

* An Irish acre contains 7840 square yards.

An

An Estimate of Expence upon a Plantation Acre of Wheat in the Drill Husbandry, the first Year.

	l.	s.	d.
To ploughing 4 times, to prepare the fallow —	2	1	4
To harrowing twice for ditto —	0	9	0
To rent for the year of fallow —	0	18	0
To harrowing with the drill harrows —	0	0	6½
To sowing with the drill-plough —	0	1	1
To seed-wheat generally 5 stone, but suppose 6 —	0	6	0
To the first, or winter hoeing —	0	1	7
To the spring hoeing with the cultivator —	0	1	1
To the third sowing, i. e. to return the meliorated earth to the corn —	0	1	7
To the fourth and final hoeing —	0	1	1
To rent, the year the corn is growing —	0	18	0
	4	19	3½

This is the same charge as in preparing for the common husbandry.
 This is the same also.
 This charge is saved after the first year.
 Four acres a day may be harrowed with one horse.
 From three to five acres may be sown in a day.
 Two acres may be hoed in a day, two horses, ploughman and driver : the design of this hoeing is to leave the plants dry, and to meliorate the earth.
 To deepen the foil, one horse, plough-man, and driver.
 To make the corn-tiller, i. e. to increase its branches.
 To fill the grain, and render it large.

Although the drill culture for the first year is very near as expensive as the common ; yet after taking the crop, the expence and labour of fallow, and the loss of time, is not to be incurred again, as is unavoidable in the common husbandry.

An Estimate of Expence upon an Acre of Drilled Wheat after the first Crop.

	l.	s.	d.
To ploughing the land once —	0	10	4
To harrowing with the drill-harrow —	0	0	6½
To sowing with the drill-plough —	0	1	1
To seed-wheat —	0	6	0
	2	17	11½
To four times horse-hoeing, as before stated —	0	5	4
To one year's rent —	0	18	0
	2	1	3½

One ploughing is all that is necessary.

Be it remembered, five stone is enough.

Thus the land is sown again with wheat every year, and instead of 4l. 9s. which is the farmer's expence in the common husbandry, exclusive of one year's rent of the land : in the drill method is no more than 17s. 11½d. and the total expence, instead of 5l. 7s. is no more than 2l. 1s. 3½d. rent included ; whereby there is a saving of 3l. 5s. 8½d. an acre.

Before the account of profit and loss upon these different methods of culture be stated, it will be necessary to take notice of an objection, which may perhaps be made to the above charge of ploughing in the common husbandry.

It is pretended, that three quarters of an acre may be ploughed in a day, with one plough ; but can it be done effectually ? The land may indeed be scratched, but cannot really be ploughed as it ought to be.

The farmer ought to be cautioned against a trick too frequently practised in ploughing.

When a ploughman enters his plough and passes across the field, he turns a sod about a foot broad ; when he is to return, he enters his plough about four feet distant from the outside of the former furrow, and so turns another sod of the same breadth, which when turned, just meets the former sod ; thus four feet of the land appear to be ploughed, whereas the fact is, that the two feet lying under the fods is not touched with the plough at all.

This deception, added to the practice of just skimming the ground, enables hirelings to undertake ploughing at six and seven shillings an acre.

But if a plantation acre of land be well and effectually ploughed, ten shillings and four-pence, as charged above, will not appear too much ; and it is, in fact, supported by the common course of business.

When wheat is to be sown, it is the general custom to send a barrel of seed into the field with two ploughs, which is to sow an acre of land, and that is the usual day's work for two ploughs in the general course of business.

Let us see, then, what the expence will amount to : eight cattle will be eight shillings, two plough-men one shilling and four-pence ; two drivers one shilling, and the seed-man eight-pence, which in all makes eleven shillings, and corresponds with the above charge.

One Acre of Wheat and Oats in the Common Husbandry, for fifteen Years.

Dr.	l.	s.	d.
To the expence on a wheat crop, 2d year	5	7	0
To the expence on an oat crop, 3d year	2	5	2
To the expence on a wheat crop, 5th year	5	7	0
To the expence on an oat crop, 6th year	2	5	2
To the expence on a wheat crop, 8th year	5	7	0
To the expence on an oat crop, 9th year	2	5	2
To the expence on a wheat crop, 11th year	5	7	0
To the expence on an oat crop, 12th year	2	5	2
To the expence on a wheat crop, 14th year	5	7	0
To the expence on an oat crop, 15th year	2	5	2
	38	0	10
To clear profit in fifteen years —	27	19	2
	66	0	0

One Acre of Drilled-Wheat, for fifteen Years:

[illegible]

To clear profit arising upon an acre of land in fifteen years in the drill-husbandry	—	—	52	3	11
To clear profit arising upon an acre of land in fifteen years in the common husbandry		—	27	19	2
Greater profit on the drilled acre in fifteen years	—	—	24	4	9

Which amounts to 1l. 12s. 3 $\frac{1}{4}$ d. *per annum*, for fifteen years on the acre, more than by the common husbandry.

In the drill-husbandry the crops are stated at three barrels of wheat less upon an acre than in the common husbandry, that it may not be supposed to be over-rated; but in the common husbandry, the crops are rated at the highest; fourteen barrels of oats an acre are also allowed in the common husbandry, which every farmer must admit to be great allowance upon the general produce.

That the drill culture will produce six barrels an acre, is fully proved in Mr. Baker's report at large, which will shortly be published, where it will be shewn, that much more has been produced.

Doubtless it will be observed, that in fifteen years fourteen wheat crops are obtained in the drill-husbandry; in the common husbandry only five wheat and five oat crops; the other five years are not only lost, but are an heavy expence to the farmer.

A farmer having forty acres of tillage, supposing him to direct his attention to bringing it to the drill culture, would make in fifteen years 969l. 10s. more than he can in the common husbandry : which is such an advantage, that the greater profit in the drilled acre in fifteen years will purchase the fee simple of that in the common husbandry, at twenty-seven years purchase, valuing the land eighteen shillings an acre.

Thus it appears, that in every fifteen years the fee-simple of all the tillage lands of the kingdom is lost to the community by the common course of tillage.

In stating these accounts, no mention is made of fences, water, cutting the land, weeding and reaping, as these articles of expence depend upon a variety of circumstances : but will, in general, be more upon the common husbandry than the drill.

M. de Chateauvieux's Account of the Crops produced during Sixteen successive Years, by Fields cultivated and sown in the common Way, and of which Part was constantly dunged; compared with a crop of the same Fields cultivated without Dung, according to the New Husbandry.

“ The result of all our experiments in agriculture would be of little use, if it extended no further than our private instruction. To render it of more general service, we shall here give a comparison of the produce of lands cultivated according to the Old Husbandry, and according to the New, that every one may judge which of the two is most likely to answer best.

“ This parallel will shew how much the New Husbandry is superior in point of advantage to the Old. We are to suppose all the circumstances of the seasons to be like those of the years of which we have compared the products. But as the expence of culture is an object well worth considering, and as that expence may not be equal in both ways, I beg leave to lay down here as a fact, That the charge of the new culture is less than that of the old.

I have tried it, and find so; as I shall, hereafter, prove beyond dispute.

“ By the old culture, in the farm which I now cultivate in the new way, I should have had but two fields sown in 1752 ; to be reaped in 1753. These two fields contain together eighteen acres, two roods, and twenty-eight poles. I have calculated their produce during sixteen years, viz. from 1730, to 1745, inclusively. They have yielded, in that time, eight crops, the total produce of which has been 146863 pounds of wheat : deducting from which, 42130 pounds for the seed sown in the eight years, the neat produce will be reduced to 104733 pounds.

It is proper to observe that this wheat was measured every year in the barn, as soon as it was threshed, and before it was sifted : an operation which always occasions a considerable diminution, though we do not make any allowance for it here.

“ Let us now see what crops the preceding experiments give us room reasonably to expect from the same two fields in sixteen successive years of the new husbandry ; to judge only by that of this first year, 1753, unfavourable as it is.

“ The first field was sowed, half in beds, and half in equally distant rows. I am obliged to suppose it to have been sowed entirely in beds ; for it cannot be doubted but that the part which was sowed in rows, would have produced as much as the other : consequently the whole crop of the two halves, at 3370 pounds each, would have been 6740 pounds.

“ Besides the advantage of reaping a much greater quantity of corn, there are others which highly merit our attention. The corn is not mixed with any seeds of weeds, and its quality is greatly improved by the abundance of nourishment which the plants are supplied with by frequent stirrings of the earth in this husbandry, more than in the old.

“ But how fine a prospect does the following proposition afford us beyond all this! viz. “ That the crops of the second and following years, would be still more plentiful than the first. What some might then think only an object of hope and speculation, is already realized, and proved by experience. All this deserves the most serious attention. The New Husbandry will certainly, in time, acquire a superiority over the Old, greater than we can now imagine.

Proofs that the best Field in the Country, though the greatest Part of it was dunged, yielded less Wheat than those in which no Dung was used. By M. de Chateauvieux.

“ The proofs of the advantages of the New Husbandry cannot be too greatly multiplied; and all those which are the result of experience, deserve to be communicated to the public.

"The field we are going to speak of, is generally, and justly, reckoned the best in the country. Its soil is excellent, very deep, and extremely fertile. This field is dunged very often. Its nearness to the farm-yards renders the carriage of manure extremely easy, and is the cause of its getting perhaps more of it than may be necessary. Its situation too is excellent, rising on all sides above the neighbouring grounds, and the highways which surround it; by which means it is less exposed to be hurt by wet, the water finding an easy drain from off it.

"The extent of this field is 6087 fathoms (four acres and eight poles.) It was sowed in 1752, for the harvest of 1753, and the greatest part of it was well dunged.

"It is not the custom of the place I am speaking of, to describe the extent of a field by the number of acres contained in it, but by the number of measures of wheat with which it is sowed. Eight measures used generally to be employed to sow this: but the quantity of seed was lessened this last time, and only seven measures were sown. We have hitherto supposed the surface of this field to be equal to that of the other fields of the same country, in which eight measures of seed are sown.

"But as I was desirous to be more precisely exact, in order to form the comparison I purposed making, I had recourse to the geometrical plans of the lands, and found the contents of this field to be, as I said before, 6087 fathoms; now, the custom of the village to which it belongs is always to sow at least eleven measures in a space like this. One field, among others, very near to this, and which is but twenty-four fathoms and thirty-two feet larger, has always been sown with twelve measures.

"A new cause of the fruitfulness of this field, unknown before my observations, is, that the farmer wisely took care to sow it with a less quantity of seed. The plants thrive better, when the land was not overstocked with them. This field will therefore help to prove the truth of one of the first principles of the New Husbandry, viz. that the quantity of seed generally used ought to be diminished: a proposition which deserves our entire confidence, because the seed here has, from time immemorial, been reduced to eight measures, and they have been sufficient to produce very plentiful crops. The farther reduction made in 1752, to seven measures, must also be approved of, since the crop which these yielded was very fine.

"These preliminary observations seemed necessary, before we proceeded in our detail. This field was sowed with about 850 pounds of wheat. It was finer during the whole summer than any wheat in the common way. It was reaped at a proper time, and yielded about 6646 pounds, from which must be deducted, first, the 850 pounds of seed: and, secondly, the value of the dung, which is equal at least to 1260 pounds of wheat, together with 2110 pounds: which deducting from 6646 pounds, the total produce leaves for the neat produce 4536 pounds.

"The crop of 1753 was diminished by the hail on the third of June. The value of this loss is not known: but we may fairly compare it with the experiment Numb. II. which likewise suffered by the same hail. We confess that this comparison is not absolutely exact, with respect to this accident; but it must also be granted, that this circumstance cannot occasion any very great error. We must likewise premise, that we shall not reckon the produce of a small spot which is pretty commonly sowed in March, in the year of fallow, because it hardly equals the expence of dung and ploughing.

"The neat produce on a field sown in equally distant rows, was 2857 pounds eight ounces. But the extent of that field being only one acre, three roods, seven poles and two yards, we must calculate what the crop would have been in proportion, if that extent had been four acres and eight poles (6087 fathoms), supposing it of the same quality. We shall find, that the field on which our experiment was made, would have produced neat 8006 pounds of wheat; deducting from which 4536 pounds, for the neat produce of the field cultivated in the old way. The difference in favour of the New Husbandry, without dung, will be 3470 pounds of wheat.

"This field laid out in beds, yielded neat 1540 pounds of wheat. Its extent is but one acre, one rood, and eighteen poles; so that we are to see what crop it would have yielded if its extent had been four acres and eight poles, supposing the quality of the soil to be the same. The Rule of Three shews us again, that its neat produce would have

been 5681 pounds of wheat, which we are to double for the amount of the next year's crop, every year yielding a crop in the New Husbandry; whereas the field it is compared with would lie fallow this year. Thus two years will yield 11362 pounds of wheat; from which deducting 4536 pounds for the neat produce of the same field, cultivated in the old way, during the same space of time, the difference will be 6826 pounds of wheat in favour of the New Husbandry."

Reflexions and Observations on the Practice of the New Husbandry, by M. de Chateaucieux.

"The chief object of our reflection last year was, the effect which ploughing and culture have upon plants. They seem to us to be confirmed by the following observations:

"1. The productions were greatest in those places where the earth has been most loosened, and brought to the finest tilth.

"2. We have seen plainly, that, in order to improve our tillage, it is necessary to make the great furrow in the middle of the alleys very deep, because that furrow being afterwards filled up, and a new bed made over it, there is a greater depth of light well-loosened mould immediately under the roots of the plants.

"3. We can affirm, that we have this year, without much trouble, ploughed our beds from fifteen to eighteen inches deep, which is very considerable; but we must not flatter ourselves, that this depth can always be attained the first year; it is by continuing this same culture that we shall insensibly reach it.

"4. To have great success, requires proper care and judgment in performing every part of the New Husbandry. The culture which is well executed will be of very great use; but that, on the contrary, which is badly done, will be of no service to the plants, and may even prove very detrimental to the next year's crop.

"5. To perform this culture with advantage, it is therefore necessary to observe this important maxim of tillage, so little attended to by many farmers, "never to set the plough to work, when the earth is too moist." I have adhered to it strictly, and have never suffered my lands to be touched till they were dry. We have tilled when the weather has been very dry and very hot, and then it was that our culture had the best effect; the stiffest land having been broken by the preceding ploughings, was provided with the moisture necessary for plants, from its surface to the bottom of the furrows; and the plants were sensibly benefited by all our frequent stirrings.

"6. I was so struck with this, that I marked several stalks, to see how much they grew each day. From the time that the ears began to appear, till they had done blossoming, I found that they grew an inch in four and twenty hours. The hottest days were those in which the stalks grew most, whilst all vegetation seemed almost suspended in the wheat in the common way.

"7. This observation led me to another. I was greatly surprised one day to find my stalks just as I had left them the day before. The next day, and the day after, I found them still the same. In short, they grew no longer from that time.

"So sudden a change raised my curiosity greatly, and I resolved to find out the cause of it. The time when they ceased to grow, was immediately after they had done blossoming. I judged that from that time all the sap was conveyed to the ear, to form the grains, and that the rest of the plant had only what was necessary to prevent its drying too soon. This dispensation of the nutritive juices seemed to me very remarkable: all the forces seem then to unite, in order to form, fill, and ripen the grain, which is the most useful part. I was afterwards confirmed in this, by observing, that it was from that very time that the stalks and blades began insensibly to lose their deep green colour, and that this green grew lighter and lighter every day; a sure sign of a diminution of sap in those parts.

"8. It is likewise of very great importance to know which is the most proper time for sowing; for the growth of plants depends greatly on this circumstance. Late sowings have not answered; but the early ones have produced plants, whose vigour has enabled them the better to resist the winter's cold, and to branch out the more abundantly. By attending to this circumstance, the farmer will enjoy the desirable advantage of having his corn ripen early, and

of its being less exposed to the dangers of the summer season; for we have seen that the wheat which was sowed first in the new method, ripened thoroughly as soon as that which was sowed in the old way. It is proper to know this, in order to be sensible of the necessity of beginning to plough early, that the seed may be sowed in due time.

"9. I must beg leave again to make a few reflections relative to the quantity of seed most proper to be sown. It is of the utmost importance to know how to proportion the quantity of the seed to the strength and richness of the soil, so that each may have its due proportion. The experiments already made, help to direct us; but I think others still necessary, before we can trust absolutely to our knowledge in this point.

"At present, I shall only advise sowing the same quantity of seed as I did in 1752. I fancy that proportion will not differ greatly from what a longer practice will shew to be best. However, the same quantity of seed will not do for every soil. It must be varied with judgment, and regulated according to the circumstances of the season, and the better or worse condition of the land. I think, too, that in the first, and even the second year of the trials which may be made, it will be proper to sow a little thicker than I did in 1752. The farmer will easily perceive, that when his lands are well loosened and brought to a good tilth, they will require less seed; but till then he will do well not to be over-sparing of it.

"10. We cannot yet determine so exactly as we could wish, what breadth the beds, including the alleys, should be of, to make the ground produce the greatest quantity of corn; nor whether it would be best to sow more or less than three rows. We confess, that we should be glad to see a longer series of accurate experiments, and to have a greater knowledge of this matter before we pretend to fix it. Our beds have always been about six feet wide.

"M. Dunamel, who first introduced this New Husbandry in France, intends to make experiments by sowing only two rows. If they should yield more grain, the breadth of the beds may certainly be diminished: and as it is of consequence to multiply and vary experiments, in order to determine this point, we now have several beds sown, some in two and some in three rows. I have likewise tried what the multiplying the number of rows in some fields would do; and the result of this experiment promises an advantage in that way of sowing. The success of this first trial was as follows:

"When the field was sowed, I observed, among the rest, ten beds which the ploughman had made wider than the others. I was sorry at first that any part of the ground should be lost; but upon second thoughts, I determined to sow those beds with two turns of the drill-plough; and consequently to plant them with six rows of wheat. I did so; and when the first ploughing after winter was given, little regard was paid to the two outside rows, which were torn up by the plough in several parts; so that there remained but four or five rows in those places.

"The wheat of these beds, not excepting even the middle rows, grew as high, and branched as much as that of the others, in which there were but three rows. I examined them frequently with great care, and was assisted therein by several persons, very capable of judging and making good observations. The only difference we could distinguish, and that was scarcely perceptible, was in the ears, which we thought rather shorter in the middle rows than in the others: but as there was a greater quantity of them, we judged that these beds would yield the most grain.

"We were not mistaken; for their produce was as follows: the ten beds sown with six rows each, yielded ninety-one pounds of wheat more than ten beds sown with three rows each. But as this result does not set the matter in a sufficiently clear light, we must have recourse to the following calculation. The six-rowed beds took up more ground than those which had but three rows: two beds more might have been made out of the surplus of their breadth; so that there would, in that case, have been twelve instead of ten. The question therefore is, whether this ground, made into ten beds, produced more than it would have done if it had been made into twelve beds of three rows each? To which I answer, that it did produce thirty-eight pounds more; and that there was likewise a seventh part more straw.

"As this experiment deserved to be repeated, I have tried it in a larger way. I have laid several acres out in

beds of about seven feet wide: they are sown with six rows: the plants are very fine, and I impatiently wait the event.

"Though I have continued not to dung my fields, the plants still grow very tall, and produce fine long ears, well filled with plump grain.

"I am indebted to the New Husbandry for the recovery and improvement of worn-out meadows. They have already yielded me plenty of fodder, the value of which ought to be added to the produce of the fields, because the New Husbandry is the immediate cause that manure can be spared to enrich those meadows.

General Disposition of the Lands for the Crop of 1754.

"The more I have studied the principles of the New Husbandry, the more I have been convinced of the advantages attending it. My experiments have not only confirmed me in this opinion, but they have likewise shewed me, that my practice has been consistent with those principles. This made me determine to lay the whole of one of my farms out in the new way, as soon as I possibly could; its extent being no more than I can direct almost the whole culture of, myself.

"I have completed it this year. All the fields, of which only half used to be sowed every year in our old way, are now laid out in beds. I have sowed them all with a design to continue doing so for the future every year. They look exceedingly well hitherto: the plants are extremely fine, and promise a greater crop next year than that of the experiments of the foregoing years.

"These experiments have likewise made a strong impression on several persons in this country, each of whom judge of the New Husbandry, as his inclination, or prospect of advantage, directed. It is true, our farmers are more generally inclined to sow their lands in equally-distant rows, with the drill-plough, than to lay them out in beds; the proper management of which, say they, is attended with much more care and trouble. My drill-plough is preferred on account of its simplicity. It began to be used last year, and numbers of fields near this city (Geneva) have been sowed with it this year.

"Several of our peasants have likewise tried the drill-plough, and their example will be of consequence hereafter. Their unwillingness to come into any new practice is well known: but this seems to get the better of their prejudices; and the prospect they now have of greater crops than usual, makes them regret their not having sowed a larger extent of ground in this manner.

"We have about an hundred and fifty acres sowed in beds, and also near a thousand sowed in equally-distant rows. Such large experiments, and made on different soils, cannot but afford new instruction: the facts will be better ascertained, and people will be more thoroughly convinced that the greater product of the crops is owing to the New Husbandry, and not to favourable circumstances, to which they are too apt to impute it. These experiments, say they, have been made of the very best soils; it is much easier to prepare two or three roods of ground, than an extent of several acres; these little spots have been cultivated with vast care: it is almost impossible to bestow the same attention upon large tracts of land.—Luckily several lovers of agriculture are making large experiments, which already prove that the New Husbandry may easily be practised in any extent of ground whatever.

CONCLUSION.

"Any one may now judge, by the experiments which have been made these last four years, and by the success which has attended them, how far the principles of the New Husbandry are justly founded, and how far we are in the right road to give still farther demonstrations of its excellence.

"The lands on which it has been already practised leave no room to doubt that all its operations may be performed with ease: and at the same time they prove, to those who shall be inclined to cultivate any part of their farms in the same way, that they may do it with equal advantage.

"Convenient instruments for executing this culture are already invented and made. The use which has been, and still is, made of them, ought to increase our confidence in them. It is by their means that the two most essential articles

ticles towards securing success, are obtained: the first is the means of forming, ploughing, and cultivating the beds, with great ease and little expence: the second, that of sowing land more regularly, and of giving it the exact quantity of seed that may be thought most proper, by means of the drill-plough, which buries the seed at its proper depth in the furrows, covers it over, and, in short, performs the whole business of sowing with great dispatch, and a considerable saving of seed."

EXPERIMENTS made near Guignes, in the Province of Brie, under the Direction of M. Roussel, and communicated to M. Duhamel in 1755.

"M. Roussel prudently began; as we would advise every one to do, with small experiments. His first trial of the New Husbandry was upon a little spot: but being prevented from attending to it in person, many faults were committed during his absence. On his return, which was towards the end of November, 1754, he inquired after his crop, and learnt with pleasure, that some grains had produced upwards of fifty ears a-piece, and that many of these ears contained sixty-four grains. This was sufficient to shew him the excellence of the new culture, which he immediately determined to extend to larger objects.

He had no time to lose. Two contiguous pieces of ground, containing twenty-four acres, had been folded, and were just going to be ploughed for the last time, in order to be sown according to the usual practice of the country. These were chosen for the farther trial of the New Husbandry, and were accordingly sown with the drill-plough, between the ninth and twenty-first of October, with 571 pounds of wheat, including ten pounds and a half which were used to fill up some spaces where the seed had missed. This is after the rate of about twenty-four pounds to an acre.

At the same time an adjacent piece of ground, which had been folded like the former, and of which the soil was equal to the best part of the field sown in rows, was sown in the common way. This last contained four acres and a half, and took up 486 pounds of seed, which is 108 pounds to an acre.

The corn came up finely in both fields: but that which was sown in rows happened to be near a wood, from which numbers of rabbits came, and entirely destroyed the plants of near five acres: the roots which they left were eaten up by worms: and the dung of the sheep-folds produced a great quantity of weeds. This was not all: as the furrows did not run in the direction of the declivity of the ground, the water lodged in them, so that the first ploughing, which ought to have been given in March, could not be performed till April, when it left a great many clods.

These clods were grown hard by the time of the second ploughing, which was performed with a plough with two mould-boards, which instead of breaking and loosening the ground, and laying fresh earth to the roots, only turned those hard clods over upon the rows.

The third ploughing, which was given with a plough with two shares, and in more favourable weather, had a better effect.

Notwithstanding the accidents which had reduced this piece of wheat to so wretched a condition, that the husbandmen said they were sure it never would produce a crop worth reaping, and that all the labour bestowed upon it was thrown away; yet, reckoning upon the same footing of twenty-four acres, though it would be but just to deduct the five which were absolutely destroyed by the rabbits: and supposing too the crops of 1756 and 1757 to be no greater than that of 1755; M. Roussel's calculation proves, that even these three crops will still be better than what the same field would produce in the common way.

But, says M. Roussel, if we do the New Husbandry part the justice it deserves, and instead of including the five acres which the rabbits destroyed, we reckon only the produce of nineteen acres prepared in a hurry, and badly ploughed; and even suppose them to be no better managed in the following years, and the whole extent of the 24 acres to be only of the same quality as the four acres and a half with which it was intended to be compared, the produce of both, in three years, will be as follows:

The nineteen acres produced 11592 pounds of wheat, which was preferred to any other for feed, not only because it was finer, but likewise because it was quite free from all

seeds of weeds. This is after the rate of 610 pounds for every acre.

From this we are to deduct the feed, which is, for each acre, twenty-four pounds.

The neat produce of each acre will then be 586 pounds of wheat, free from all seeds of weeds.

Supposing the crops to be no greater in the following years, though what we shall say hereafter will shew that they certainly will, each acre will have produced neat, at the end of three years, 1758 pounds of wheat.

The other piece of ground, which was cultivated in the old way, in order to make the comparison, produced 1260 pounds an acre, from which we are to deduct 154 pounds for the feed.

The remaining neat produce is 1106 pounds.

The second year's produce of this same acre, sowed with spring corn, can be reckoned at only half the value of the first year's crop of wheat; and the third year produces nothing, being the year of fallow.

Thus the total neat produce of the acre cultivated in the common way will be, at the end of three years, only 1659 pounds; whilst that in the new way will be 1751 pounds."

M. Roussel gives the following Account of his Experiments in 1756, in a Letter to M. Duhamel.

"In October 1755, I chose in the middle of a fallow field which had been well ploughed, and was not exposed to any of the accidents I met with last year, a piece of ground, which, to make a fair comparison between the new method and the old, I divided into two equal parts, each containing twelve acres. One of these spots was set apart for the New Husbandry: and the other, exactly of the same quality, and quite contiguous, to be sowed broad-cast in the old way.

"This last ground had been extremely well dunged by the folding of the sheep. With regard to the other, which was to be cultivated in the new way, and which composed ninety-three beds five feet wide, including the alleys; only eight of these beds were dunged by sheep, and that at the same time, and to the same degree as the ground by which the comparison was intended to be made: of the other beds, seventy-six had no sort of dung or amendment whatever; and nine were dunged more or less, in the manner and proportion hereafter mentioned.

"Most of those who practise the New Husbandry use no dung at all. I supposed that their reason for rejecting this manure was, the difficulty of finding a proper time to apply it; for whilst their alleys receive their several stirrings, no wheel-carriage can be admitted with dung, without hurting the beds which are sown, and hardening the loose mould of the alleys: to carry it on the backs of cattle would be at best a very difficult, tedious, and expensive way, where any considerable space is to be dunged: to spread it upon the earth only the moment the seed is sown, is a sure way to clog up the drill plough, and hinder its operation, if the dung be not thoroughly rotten; and to breed weeds, which by no means suit this culture. To remedy these inconveniencies, I contrived the following method: I opened in each of the alleys, one of those large furrows which must always be every year at the concluding of the summer hoeings, in the place where the three rows of seed are afterwards to be sown; and by drawing the plough with two mould-boards once through it, I made it fourteen or fifteen inches wide; which is the breadth that the three rows of seed require. The space between two of these deep furrows is exactly the breadth of a cart, the wheels of which going in them, hurt no part that has been ploughed, and do not press down or harden the loose mould; nor do the horses do any damage, because they necessarily tread upon the stubble of the late-reaped beds, in the middle between these two furrows. This was the method I used to dung the nine beds in question. The dung was well rotted: it was spread at the bottom of the furrows, and immediately covered over by the same ploughing that made the beds which were sown some days after. Perhaps this manure may be of more service to my lands than to many others, because the soil is naturally cold and backward. The grain is by this means sown upon a kind of gentle hot-bed, the warmth of which promotes the branching and vegetation of the plants. The winter rains and frosts raise a fermentation. The first spring ploughing, by giving it a little air, revives that fermentation at the very time when the sap

is most active, and the plant begins to branch. As the dung rots, a kind of motion is caused in the earth, which in some measure answers the end of a slight ploughing, and brings fresh nourishment to the roots. The same heat as consumes the straw likewise consumes the little seeds that are in the dung, which might otherwise produce numbers of weeds. When this dung is brought up again to the surface of the earth, by the next year's ploughings, it will no longer have those hurtful seeds. It will indeed have lost its heat, but it will still have retained all its fatness, which will mix with the earth; and land, thus constantly dunged, will in time become a perfectly fine mould. But if these layers of dung should be spread too thick, or the dung itself be of too hot a nature, the roots of the corn might perhaps be endangered thereby. It was to determine this that I tried the following experiments, to know the effects of different dungs, and what quantity it is proper to employ.

Three beds were dunged, in the above manner, with horse-dung; the first, which was 1165 feet long, had three loads of dung; the second, of 1171 feet, had but two and a half; and the third, 1183 feet, had but two. Three other beds were dunged with cow-dung: one of 868 feet, with two loads and a half; and the second of the same length, with two loads; and the third, of 874 feet, with only one load and a half. The three remaining beds had sheep's-dung: the first of 842 feet, two loads; the second, of 838 feet, one load and a half; and the third, which was of the same length, one load.

These beds were distributed in such a manner, that each of them was in the middle of two other beds which were not dunged. The field, thus laid out, was sown on the thirteenth, fourteenth, fifteenth, and sixteenth of October, with the drill-plough, which plants three rows in each bed. I used 378 pounds of seed; and afterwards ten pounds to fill up the chasms; which is after the rate of thirty-two pounds six ounces to an acre, and consequently a little too much. Accordingly, when the corn came up, I saw it was too thick sown. The reason was, that the grain was too small in proportion to the outlets of the drill-plough. At the end of ten days this corn rose well. On the eighteenth of December, I observed that most of these plants had branched into four stalks, whilst those in the common way had but three. I perceived no sensible difference then between the dunged and the undunged bed. It was not till the twenty-fourth of January that I saw plainly that the plants of the dunged beds were of a deeper green, and had made longer and more vigorous shoots than those of the undunged beds. By the twentieth of February, five smaller stalks issued out of the five great ones, which was not the case with the wheat in the common way. The alleys did not receive their first ploughing till the 10th of March. Eleven of the main stalks grew an inch and a half in five days; and I observed that the moles were rather more busy in the dunged beds than in the others. As the earth was yet somewhat too soft, I thought it needless to continue a ploughing which could not do any good, and therefore postponed it to the 28th of March, and following days. On the 9th of April, I found a plant with eighteen stalks in one of the dunged beds: the greatest number of branches that any of the plants in the undunged beds had, was twelve: but, on the other hand, I likewise found some which had eighteen in the field of comparison, sown in the common way.

On the 9th of May, this same plant had twenty stalks; and from that time it branched no more. The second ploughing was not given till three weeks after, viz. the 28th of May; which, I think, was somewhat too late after the corn had ceased to branch. By the 23d of June there were three sorts of wheat to all the beds: there were ears in blossom, others just going out of bloom, and others not yet out of their hoods. The finest ears were those which came up and blossomed first. The most forward beds were those which had been dunged under furrow with sheep's-dung: the next to them were the eight beds which had been folded, the plants of which were a little greener than those of the undunged beds.—The last ploughing was given on the tenth of July. The grain had then begun to fill: but that in the common way was the most forward, though it was sowed three weeks later than the other. I know not for what reason, the wheat of the New Husbandry began to be reaped on the 4th of August, and that in the old way was let stand till the thirteenth. The produce of both cultures was as follows:

In the twelve Acres cultivated in the new Way, the three Beds dunged with Horse-Dung, yielded,

The first, 1165 feet long, dunged with three loads	19
The fellow to it, not dunged,	15
The second, 1171 feet long, dunged with two loads and a half,	18
The fellow to it, not dunged,	14
The third, 1183 feet long, dunged with two loads	16
The fellow to it, not dunged,	13

The three Beds dunged with Cow-Dung yielded,

The first, 868 feet long, and dunged with two loads and a half,	16
The fellow to it, not dunged,	11
The second, likewise 868 feet long, and dunged with two loads,	15
The fellow to it, not dunged,	12
The third, 874 feet long, and dunged with one load and a half	14
The fellow to it, not dunged,	12

The three Beds dunged with Sheep's-Dung, yielded,

The first, 842 feet long, and dunged with two loads	17
The fellow to it, not dunged,	10
The second, 838 feet long, and dunged with one load and a half	15
The fellow to it, not dunged,	11
The third also 838 feet long, and dunged with one load	14
The fellow to it, not dunged,	10

The eight Beds which had been folded, two of which were

1171 feet long, three 1177 feet, and three 1183, produced in all	142
This is near 18 sheaves a-piece.	
The 67 other beds which had not been dunged, produced in all	814
This is somewhat more than 12 sheaves a-piece.	
Total produce of the 12 acres cultivated in the new way,	1208
The twelve acres sown in the common broad-cast way, after having been well folded all over, produced	1820

These facts shew the advantage of dunging in this manner. It is plain that the best dung is that of sheep, and that it is more profitable when laid under furrow, than when it is spread upon the surface of the ground by folding.

In proportion to the produce of the bed, 842 feet long, which was dunged with two loads of sheep's dung, and produced seventeen sheaves; the bed 1165 feet long, which was dunged with three loads of horse-dung, and produced only nineteen sheaves, would, if dunged with sheep's-dung, have produced $23 + \frac{16}{3}$; and the bed dunged with cow-dung, which yielded but sixteen sheaves, would have yielded $17 + \frac{16}{3}$.

The eight folded beds, whose whole length was 9412 feet, would have yielded 190 sheaves $+ \frac{16}{3}$, instead of only 142 sheaves, which was the amount of their product.

It is likewise plain, that if the whole of my twelve acres in the new way had been dunged with sheep's-dung, as the bed 842 feet long was, I should, in the same proportion, have reaped 1700 sheaves, which would be but 120 sheaves less than the whole produce of the twelve acres folded all over, and sown in the broad-cast way. But even then, I say that those 120 sheaves would not be equivalent to the quantity of grain which I saved by sowing according to the New Husbandry. An hundred of our sheaves yielded, in general, little more than 378 pounds of wheat. The 120 sheaves which the twelve acres sown in the broad-cast way produced more than the twelve acres in beds, would therefore yield but 453 pounds. Deduct this from 871 pounds, which I saved in the seed of these last twelve acres sown in the new way, and I shall still be a gainer: for I sowed only 388 pounds in this ground; whereas 1260 pounds were used to sow the other twelve acres in the common way. This would have been the produce of this first year's crop, supposing that the whole

of my twelve acres in beds had been dunged in the same manner as the bed 842 feet long. For want of that, I reaped but 1208 sheaves. They have just been threshed, and have yielded only 5040 pounds of grain."

M. Du Hamel makes the following remarks on this account of M. Roussel:

"The 1208 sheaves yielded but 5040 pounds of grain, from which we are to deduct 388 pounds for the seed.—The neat produce is therefore 4652 pounds, which would make in three years 13956 pounds. The other field in the common way produced 8757 pounds, from which we are to deduct 1260 pounds for the seed: the neat produce is consequently 7497 pounds; the half of which is 3748 pounds and an half: for the value of the next year's crop. This is all that the twelve acres in the common way would produce in three years, and amounts to no more than 11245 pounds and a half: consequently the balance in favour of the New Husbandry in three years, is 2710 pounds and a half, or one fourth part of the whole: and that from a field which was sown in rows for the first time, and of which three-fourths were not dunged at all: whilst the other, with which it is compared, had been solded all over, and for the year, produced a very plentiful crop."

Extract of a Letter from a Gentleman in Poitou.

"Being convinced of the advantages of the new method of cultivating land, I resolved to make a trial of it, by comparing the produce of a field cultivated in the common way, with that of another field cultivated according to the New Husbandry: and M. Du Hamel has desired all lovers of agriculture to try by experiments made with care, whether it be most profitable to sow beds with two or with three rows of corn; or, which is the same thing, to find at what distance the rows ought to be sown; I divided a spot of ground into ten equal parts, which I made into as many beds, each six feet wide.

"In the middle of five of these beds, I sowed three rows, seven inches asunder; so that they took up fourteen inches of ground, and there remained four feet ten inches for the breadth of the alleys, which is very sufficient for the horse-hoeing husbandry.

"I sowed three other beds with only two rows, a foot distant from each other; consequently the alleys were five feet wide.

"The two remaining beds were sown with two rows each, three feet asunder. The alleys were therefore but three feet wide: or rather the whole of this last spot may be looked upon as sown in single rows, with alleys three feet wide, which is too narrow a space to admit of horse-hoeing them conveniently.

"Before I speak of the produce of these beds, it will be proper to observe—

"1. That this trial was made with rye. My fear that birds might eat up the wheat, made me prefer rye, which I advise every one to do, when only small experiments are made. This escaped without the least damage; whereas I have observed, that when experiments have been made with wheat, the birds, preferring that to any other grain, have always destroyed a considerable part of the crop.

"2. The beds sown with three rows were near a hedge, which greatly damaged two of them, either by its roots exhausting the ground, or by its shadow keeping that part harder frozen than the rest.

"3. The intervals were not hoed at all, between either the double or the triple rows; only the alleys were horse-hoed; and consequently none but the single rows were hoed on both sides.

"4. On the 25th of February, the alleys were ploughed. I visited them on the second of March, and found, upon examining the plants, that, in these five days, they had shot out roots four inches long into the new stirred mould. I repeated the hoeings at proper times, and the rye continued in good condition till it was reaped. The last hoeing was given after the blossoming was past.

"5. I then examined the roots, and found they had extended eighteen inches into the loose mould. This may seem strange; but I am certain it is true; for I took every precaution not to be deceived.

"6. The alleys between the single rows were hoed but twice, being too narrow to admit the plough after the plants had begun to branch. However, I had not reason to complain of the produce of these single rows.

"Having now given an account of my operations, it is time to speak of the products.

"The ears in my rows were four to seven inches long, and the stalks from four to six feet high, which was one third taller than in the neighbouring fields, cultivated in the old way.

"This spot of ground, in the best years never produced more than five bushels, including the bushel of seed corn; for that was the quantity generally used: in common years, it has not yielded above four bushels, and frequently much less. We therefore cannot reckon its produce, one year with another, at more than four bushels, including all faulty grains, and seeds or weeds, which fall through the sieve, and remain mixed with the good grain. This year it has yielded me seven bushels of fine clean rye, considerably larger than the common sort. I make no account of the seed, the quantity was so small.—To prevent this grain's being mixed with any other, and at the same time to judge more exactly of the produce of my ground, I had the sheaves threshed out close by the field; but it was in the middle of a road, where all the grains scattered by the flail could not be gathered up; by which I reckon I lost more than the amount of the seed that was sown in the rows. The produce of my little field was therefore this year, compared to other years, as seven is to four; to which must be added, that it is capable of bearing as great a crop every year, which is not the case of the common husbandry.

"Let us now examine the produce of the rows, and compare them with one another, in order to judge whether it be most profitable to sow in single, double, or triple rows.

"Two beds, the most distant from the hedge, sown with triple rows, yielded each three quarters of a bushel.

"Two beds with double rows, yielded each two thirds of a bushel; consequently the three beds with double rows yielded two bushels, and the six rows sown two and two, in three beds, yielded one quarter more than the six rows sown three and three in two rows; but two beds of three rows a-piece, yielded one ninth more than two beds of only two rows a-piece; whence we may conclude, that the distance of the rows increases the product of an equal number of plants; or which comes to the same, that an equal quantity of seed will produce more grain when the rows are more distant, than when they are sown closer together. But this is not a real profit; because the six double rows take up one third more ground than the six triple rows.

"Each of the single rows yielded seven-eighths of a bushel, which is one seventh more than the triple rows, though they took up no more ground; and their produce would probably have been greater, if they had been hoed two or three times more.

"It appears by this account, that the profit would probably have been on the side of the double rows, if the alleys had been made only four feet wide, instead of five; for by this means I should have gained one fifth more ground; and four feet are a sufficient breadth for the operations of the horse-hoe. Where the single rows are so near, as in this experiment, the same ground would scarcely bear another crop the next year, for want of having been sufficiently stirred. To clear up this point by a new experiment, I have sown single rows in the middle of four beds, two of which are four feet wide, and the two others only three. The winter hoeings have been given them with ease, and I hope the others will not be more difficult, at least till all the corn is spindled. What I fear most is the earth's being carried off the narrow space on which the rows stand, when a thaw comes on, or by the heavy rains which are frequent with us.

"The rest of my field is sowed in two rows, in beds four feet two inches wide. I have done this, because, as it is the general custom here to make our ridges about that breadth, I am in hopes that if I obtain a plentiful crop, I shall be able the more easily to prevail on the farmers of this country to adopt a method, the advantages of which I am sensible before I tried the above experiments."

As it will doubtless be expected by our readers, that the advantages resulting from both the Old and New Husbandry should be set in the clearest and most conspicuous point of light under this article, we shall add here two calculations that lately appeared in the *Museum Rusticum*, and seem to be made with great accuracy and candor.

The Profit attending Arable and a Pasture Land compared, as found by Experience, near Bury, in Suffolk.

"The following calculation of the different profit attending arable and pasture land in my neighbourhood, is drawn up not merely from fancy, but from the exact accounts I have kept of my own crops, and the information I have gained from several sensible farmers.

"I take twenty acres, and suppose them an addition to a farm; but I should premise such an one as will require some additional cattle to be kept for it, perhaps two horses; but a farm of fifty pounds per annum may be so circumstanced as to require no material standing expences extraordinary for such an addition; in which case the ploughings, &c. will not cost near what I have laid them at; but the fairest way is the supposition I have made. We reckon that nothing is either got or lost by four shillings per acre for a clear earth.

Calculation of the Expences and Profit of farming a ploughed or pasture Field of twenty Acres for nine Years, on a Supposition that it is not a Farm by itself, but an Addition to another of fifty Pounds per Annum, the Soil wet, and a loose Woodcock, Brick Earth, on the Surface, for eighteen Inches deep, and under that a very good stiff Clay, improved by Land draining.

141 9 9 Total profit in nine years.

Which is fifteen pounds, fourteen shillings, and eight-pence per annum, or rather better than fifteen shillings per acre.

But I should observe, that as a crop of clover-feed is the most uncertain and various of any that is grown, I have reckoned less for it by far than multitudes produce, though at the same time many bring nothing at all.

I know a field of twenty acres, which I have been often told by several who knew the crop, once produced the farmer five bushels per acre. It was all down on a Friday, and the farmer suspecting a change of weather, by great rewards to his workmen, and bringing casks of ale into the field, and feeding them well, tempted them to work in an extraordinary manner all the Saturday, and cleared the whole into barn. It began raining in the night, and so much succeeding bad weather came, that the crops were, in general, greatly damaged. His produced, as I said, one hundred bushels, all which he sold at three pounds ten shillings per bushel, arising to three hundred and fifty pounds. And a few years ago I saw the same field with a crop of clover, which did not produce twenty pecks, and that so wretched as to fetch nothing.

I read this calculation to a farmer, and he observed, that I should reckon eighty bushels for the crop; and as it is often grown, I will give you another total, with that alteration, that your readers may adopt either, according to their idea of the chance.

Profit	l. s. d.
Lois	248 13 9
	56 16 0
	191 17 9

which is twenty-one pounds, six shillings and five pence per annum, or better than a guinea per acre.

As I mention back-carriage in this calculation, I will explain my meaning. We generally carry our corn to Ipswich, Manningtree, or Thetford, from which places we load home with coals for blacksmiths, or any persons that want them, who pay us eighteen shillings for the carriage of a loading, twelve shillings per chaldron, and we generally bring one and a half. But as we may accidentally carry our corn where none is to be had, I make such allowance as to bring it near the truth.

Calculation of nine Years Expences and Profit of twenty Acres of Grass-Land, the Soil supposed to be the same as the above Arable-Land, with no other Difference than being Grass or ploughed.

First Year's Expences.	l. s. d.
Rent, &c.	15 0 0
Mowing, making and cocking ten acres of grass to hay, at three shillings per acre, with beer	1 10 0
Stacking, loading, &c. of ten loads of hay	1 10 0
Expences on four goings of hay when it is fold, weighing, and market	0 16 0
	18 16 0

N. B. Nothing is reckoned for carriage, as manure is brought back
Fifteen old crones, bought in August
Expences in buying sheep
Three cows at five pounds each
A fow, and ten pigs, three weeks old
Supposing two acres to be manured each year with twenty-six loads per acre
Forty loads of clay, at two-pence halfpenny per load
Twelve ditto of ashes, mortar, or rotten dung, brought from Bury; six waggon loads; at eleven shillings and six-pence per load
Expences of carrying it on, and spreading, &c.
Turning and mixing manure

Which is twenty three pounds eleven shillings and two-pence per annum, or one pound three shillings per acre profit.

The above account displays the vastly superior advantages of grafs, with us, to arable land.

You will certainly remark, that nothing in the above account is reckoned for losses of stock; but in answer to that, I should observe, that nothing is calculated in the arable account for some bad years, when in such land not a quarter of a crop is produced: and I do not mean this calculation as perfect (that is impossible) but only to discover the proportion between the one method and the other; and from what I have observed, and gathered from the information which the most intelligent farmers can give me, I am clear of opinion, that the chances, on the whole are much in favour of the grafs-land, the crop of hay and seed being much more regular than those of corn, clover, or turneps; and supposing the eighty bushels of clover-seed, yet the grafs profit far exceeds the arable, even then; but, as I observed, the probability lies against the latter, supposing the profit to be only fifteen pounds fourteen shillings and eight pence per annum.

I may remind you, that I supposed this twenty acres to be an addition to a farm, not one by itself, and so compared the respective profits; therefore I have not allowed any thing for the seed which the above-mentioned cattle may accidentally have on the arable land, or turneps which they may expend in the winter; and for this reason, because although it appears to me that grafs is the most profitable husbandry, yet a certain quantity of ploughed land should undoubtedly be a part of every grafs-farm, for the raising turneps, some artificial grafs, and clover enough for the winter's food.

I hope your readers will peruse this calculation with candour, and believe me, when I assure them it is the nearest truth of any I can make, either from my own experience, or best information. *Museum Rusticum*, vol. III. p. 317.

State of the Expence of a hoed Crop of Wheat, and the Profit of it compared with that of the common Husbandry.

I propose here to state the expence of a hoed wheat-crop. If this is done in any place where the price of labour is

known, it will be easy from thence to calculate the expence of such crops in any other places.

When wheat is to be horse-hoed, it is planted upon three-bout ridges, about four feet and eight or nine inches broad. If the soil is poor, they may be made broader, but should not be much narrower, otherwise there will not be room enough to plough the intervals. Two rows of wheat, about ten inches asunder, are drilled upon the top of each ridge, and then the intervals or spaces between the double rows will be about three feet and ten inches wide.

For the first crop the land should be well prepared, and very clean: it will therefore cost more than the following crops; and if the land is not in good heart, the first crops will be the smallest, for hoeing greatly improves it. The following estimate is of the succeeding crops.

The necessary culture for these is, once ploughing in autumn, to form the new ridges for the next crop. This may be done with three horses: for the intervals, by frequent hoeing, are kept in fine tilth, and are ploughed at one bout; and in the middle of the ridges where the crop stood, being only the breadth of two narrow furrows, are easily ploughed at another bout: so that these ridges, which in common ploughing required three bouts with four horses, are now ploughed at two with three horses.

The intervals, after the corn is planted, are hoe-ploughed at one bout, to or from the rows. They are usually thus ploughed four times, once in the beginning of winter, and three times afterwards in the spring and summer.

The ten inch partitions, or spaces, between the rows of wheat, are hand-hoed about the end of March: once is generally sufficient, because the wheat soon afterwards spreads, covers the partitions, and keeps down the weeds. The rows are also to be weeded. This is all the ploughing and hoeing that is commonly necessary till harvest. But as in some years it may be proper to plough the ridges in autumn at five or six furrows, or plough them twice, sometimes to hoe-plough the intervals more than four times, or to give them a trench-ploughing, where the staple is deep enough to admit of it, I shall make a full allowance for these, and charge two ploughings and six horse-hoeings every year.

The hiring price in some parts of Middlesex for ploughing a strong loam the first time, in the common way, is seven or eight shillings an acre; I shall say eight shillings. They work about eight hours, and plough about an acre a day with four horses. The price of the labour may be thus distinguished: to the ploughman twenty-pence, and the boy eight-pence a day, including their beer; and then the horses and harness, &c. will come to seventeen-pence a day each. Twice ploughing therefore in autumn, with three horses, comes to eight shillings and nine-pence.

The tops of the ridges are to be rolled with a light roller, or harrowed once or twice with two very light harrows, to break the clods, and lay the tops of the ridges smooth for drilling. The harrows are fastened together by a pole; and a horse, walking in the furrow, draws the two harrows, one upon each ridge. A rolling in the same manner is also useful in the spring, when the earth is pretty dry, and before the partitions are hoed. These rollings and harrowings, of two ridges at once by one horse, are done at a small expence; and not being necessary every year, may cost about four-pence: but to make the total an even sum, I shall charge for them (and uncovering the plants, if any clods happen to fall upon them at the first hoe-ploughing) seven-pence half-penny per acre.

The usual quantity of seed is three pecks, and if it costs five shillings and six-pence per bushel, is four shillings and three half-pence per acre. The drilling is performed by a man and boy, and one horse. They may drill six acres a day: I shall say but five, which is nine-pence per acre.

The intervals should be kept in fine tilth: they are hoe-ploughed at one bout: three horses are sufficient for the first two hoeings, and two for the rest. I shall reckon three for each hoeing, and then six hoeings come to thirteen shillings and two-pence.

The price for hand-hoeing of beans the first time is five shillings per acre; I shall call it six; and as the ten inch partitions, and about two inches on each outside of the rows, is the whole to be hand-hoed (for the hoe-plough does the rest) these are about one fourth part of the ridge, and should be done for eighteen-pence an acre: but it is a good way to agree with the hoers to cleanse the rows also of weeds, and as these ought to be well done, they expect something more than for common work, and they will cost near half a crown per acre.

For reaping, the prices are various; from five or six, to ten

ten shillings per acre; at a medium, eight shillings is a high price. The drilled wheat, having scarcely any weeds in it, and standing upon only about a fourth part of the ridge, is easier and much quicker reaped than sown wheat, and not really worth above half the common price; but, for the above reason, I shall allow, for reaping and carrying, six shillings per acre.

Wheat-straw is a valuable article in the neighbourhood of London; and the straw, chaff, &c. might be reckoned here to pay for threshing and carrying the corn to market: where it is otherwise, an allowance is to be made. And as the distance from the market is uncertain, I shall charge the carrying out, and at market, a shilling per quarter, besides the value of the straw.

Some estates are tythe-free; others pay in kind, or a modus. I shall reckon the tythe at four shillings per acre.

Suppose the rent is sixteen shillings per acre, there remains to be added the taxes, or rates payable by the tenant, which at two shillings in the pound-rent, come to nineteen-pence per acre.

I reckon nothing for dung or manure; for land that is proper for wheat, allowing sufficient intervals and hoeing, requires none. If the wheat of the first crops is weak in the spring, a top-dressing of the rows will be of service, or afterwards, if the proper hoeings have not been given the preceding year; but this seldom happens; for hoeing makes the plants strong, and then also top-dressed, they would be in danger of lodging.

The whole expence, at these prices, of horse-hoed wheat, is, per acre, as follows:

	l.	s.	d.
Two ploughings in autumn, with three horses	0	8	9
Harrowing, seed, and drilling	0	5	6
Six hoe-ploughings of the intervals, with three horses	0	13	2
Hand-hoeing, weeding, and harvesting	0	8	6
Carrying out twenty bushels, and at market, (besides the value of the straw and chaff) at one shilling per quarter	0	2	6
Tythe, rent, and taxes	1	1	7
	3	0	0

This is the whole expence, supposing the soil to be a strong loam, the wages high, and the horses hired; but when done by the farmer's own horses, or the soil lighter, and they work more hours in a day, the expence will be a great deal less, as we shall see below: in some places it will not much exceed half this sum.

It has been already shewn, that one hundred acres of horse-hoed wheat, much of it a light, poor soil, produced near twenty bushels per acre; and that a strong soil, by a medium of twenty hoed crops, produced about twenty-four bushels per acre, both nine gallon measure; and therefore we might reckon here a middling crop about twenty-four bushels: but to avoid all suspicion of partiality, I shall suppose, that a good loam may, one year with another, produce only the least of these, or twenty bushels per acre.

The mean price of wheat at Windsor market, for the last twenty years ending at Michaelmas, 1762, is nearly four shillings and eight-pence three-farthings per bushel, and twenty bushels, at this rate, come to four pounds fourteen shillings and seven pence; so the profit of the horse-hoed wheat is one pound fourteen shillings and seven-pence per acre, or above two rents.

Your ingenious correspondent has above stated the produce and expence of twenty acres of arable land for nine years, according to the course of husbandry practised in his neighbourhood, I shall, by way of comparison, calculate the profit of these twenty acres, supposing they had been under crops of hoed wheat during these nine years.

I reckon, from your correspondent's account, the wages of his ploughmen to be about fourteen pence, and a boy four-pence a day (if not allowed beer) and the horses a shilling a day each; in all, five shillings and six-pence, besides repairs: and if they work more than eight hours, his land being lighter than the above, they may plough about an acre and half a day, which brings the price for ploughing to near his reckoning of four shillings per acre. If this is not exact he will rectify it. I shall state the plough-

ings and horse-hoeings in this proportion, and allow three horses, though fewer will do in this land. The rent-charges, I suppose, include the tenant's taxes; if not, they are to be added to the expence. As the tythe is not mentioned in his account, I do not charge it here. The other items are computed in proportion to his, and the above state of the expence: and as I abated four bushels in the above crop per acre, I shall do the same here, and reckon a middling crop of hoed wheat at only eighteen bushels; his producing, by a medium of three crops, twenty-two bushels and two fifths per acre. The expence of a horse-hoed acre of this land will be nearly as follows:

	l.	s.	d.
Twice ploughing in autumn, with three horses, and harrowing	0	3	0½
Seed three pecks (fifteen shillings and four pence per coomb at a medium) and drilling five acres a day	0	3	4½
Six hoe-ploughings with three horses	0	4	0
Hand-hoeing (at four shillings per acre, reckoned for turneps in the account) and weeding	0	1	8
Harvesting, three shillings and nine-pence: threshing four coomb and a half, four shillings and ten-pence	0	8	7
Carrying out four coomb and a half, and at market	0	4	1½
Rent charges	0	15	0
Total expence per acre	1	19	9½

The three crops of wheat were sold, at a medium, for fourteen shillings and five-pence and four sevenths per coomb, which, for eighteen bushels, comes to

3 5 0½

Profit per acre 1 5 3

The twenty acres, in nine years, produced seven crops, valued at five hundred and three pounds; but in the ninth year, the crop of sixty coomb is cast by mistake at eighty-seven pounds, which should be but half that sum; deducting therefore forty-three pounds ten shillings, the produce amounts to

459 10 9

The expence of these twenty acres in nine years, as charged

361 10 3

To which is to be added for four hundred loads of dung

20 0 0

381 19 3

Remains the profit in nine years

77 19 9

Which is, per acre per annum, near

8 8 8

There were eight hundred loads of dung laid upon these twenty acres; but it is hardly to be supposed, that half that quantity could be made from the seven crops; so that at least four hundred loads must be had elsewhere; and the dung is at a high price in that neighbourhood. I have charged but a shilling a load for it.

But if it should be supposed, that more than four hundred loads could be made from these seven crops, it must also be admitted, that a quantity in proportion would be made from the nine crops of wheat, which not being necessary in the hoeing culture, is worth, to be sold, more per load than I have reckoned above; and the value of it should then be added to the profit of the hoed crops.

Let us next compare the whole profit of these twenty acres in nine years, in both these methods of husbandry.

	l.	s.	d.
The profit, in nine years, of the hoed crops, amounts to	227	5	0
The profit in that time by the common husbandry	77	19	9
Balance in favour of the New Husbandry	149	5	3

Hence appear the great superiority of the hoeing culture; and even allowing the clover had produced four bushels of seed per acre, the New Husbandry is still by far most profitable.

JACK

J.

JACK, an instrument for turning the spit; also a contrivance for supplying the place of a boy in pulling boots off. It also signifies a support for sawing wood upon.

JAMOCK, or *jannock*, oaten bread made into large loaves.

JARDON, a name given by farriers to a swelling on the out-side of the back of a horse.

It generally proceeds from blows and kicks of other horses; but frequently happens to managed horses, by setting them on their haunches: it is seldom attended with much lameness, unless it has been neglected, or some little process of the bone broken. It should be first treated with coolers and repellents, such as hot vinegar, verjuice, &c. but if any swelling continues hard and insensible, the best way is to blister or fire; but mild blisters alone generally succeed. *Bartlet's Farriery, p. 263.*

JAUNDICE, a distemper incident to horses, and generally called, by farriers, the yellows.

Horses are frequently subject to this distemper, which is known by a dusky yellowness of the eyes; the inside of the mouth and lips, the tongue and bars of the roof of the mouth looking also yellow. The creature is dull, and refuses all manner of food; the fever is slow, yet both that and the yellowness increase together. The dung is often hard and dry, of a pale yellow, or light pale green. His urine is commonly of a dark dirty brown colour; and, when it has settled some time on the pavement, it looks red like blood. He stales with some pain and difficulty, and if the distemper is not checked, soon grows delirious and frantic. The off-side of the belly is sometimes hard and distended; and in old horses, when the liver has been long diseased, the cure is scarce practicable, and ends fatally with a wasting diarrhoea: but when the distemper is recent, and in young horses, there is no fear of a recovery, if the following directions are observed:

First of all bleed plentifully; and give the laxative clyster, as horses are apt to be very costive in this distemper; and the next day give him this purge:

Take of Indian rhubarb, powdered, one ounce and a half; saffron two drams; succotrine aloes six drams; syrup of buckthorn a sufficient quantity.

If the rhubarb should be found too expensive, omit it, and add the same quantity of tartar, and half an ounce of Castile soap, with four drams more of aloes. This may be repeated two or three times, giving intermediately the following balls and drink:

Take of Æthiops mineral half an ounce; millepedes the same quantity; Castile soap one ounce: make into a ball, and give one every day, and wash it down with a pint of this decoction:

Take madder root and turmeric of each four ounces; burdock roots sliced, half a pound; Monk's rhubarb four ounces; liquorice sliced two ounces; boil in a gallon of forge water to three quarts; strain off, and sweeten with honey.

Balls of Castile soap and turmeric may be given also for this purpose, to the quantity of three or four ounces a day, and will in most recent cases succeed.

By these means the distemper generally abates in a week, which may be discovered by an alteration in the horse's eyes and mouth; but the medicines must be continued till the yellowness is entirely removed. Should the distemper prove obstinate, and not submit to this treatment,

you must try more potent remedies, viz. mercurial physic, repeated two or three times at proper intervals; and then the following balls:

Take salt of tartar two ounces; cinnabar of antimony four ounces; live millepedes and filings of steel, of each four ounces; Castile or Venice soap half a pound: make into balls of the size of pullets eggs, and give one night and morning, with a pint of the above drink.

It will be proper, on his recovery, to give him two or three mild purges, and, if a full fat horse, to put in a rowel. *Bartlet's Farriery, p. 156.*

ILES, or *oiles*, the beards or the ears of barley, wheat, &c.

INCLOSURE, the separation of common grounds into distinct possessions.

The inclosing lands, and dividing them into different fields, pastures, &c. is a most essential part of their real improvement, and attended with many very considerable advantages, of which we shall here mention only the following:

Inclosures ascertain to every man his just and due property, and thereby prevent infinity of trespasses, injuries, and other sources of ruinous litigation. They keep the land warm, and add to its fertility, by screening it from violent and nipping winds, which otherwise frequently destroy whole crops; and they also defend it from those drying and scorching winds, which so often blast at once the husbandman's, till then well grounded, expectations. They afford shade in the summer, and shelter in the winter, for cattle, which would otherwise destroy more with their feet than they eat with their mouths, and which, for want of these, might, as Mr. Worlidge observes, lose more of their fat or flesh in one sultry day, than they gain in three cold ones. Their cuttings afford fuel to the industrious husbandman, and, if carefully planted and preserved, they will here and there furnish him with timber for his carts, ploughs, and other utensils, besides sometimes useful fruits. They are an excellent encouragement to good husbandry, and a great remedy against beggary, by employing many poor people in the labour which either the making, or the mending of them constantly requires, and which is amply repaid by the increase of crops: for it hath been remarked, not only that well inclosed countries generally maintain treble the number of inhabitants, or more, than the champaign; but also, that those inhabitants are much better fed and clad, than the common run of people in uninclosed lands. To be convinced of this, let any one but examine our vast downs, commons, heaths, wastes, and unimproved forests, badges yet remaining, as Mr. Worlidge properly terms them, of poverty and idleness; but at the same time, thoroughly susceptible of being converted, with proper care, into corn and pasture fields, meadows, garden, orchards, and pleasant groves, the marks of industry and good husbandry. Let him but compare the naked parts of Wiltshire, Gloucestershire, Surry, &c. with the delightful parts of Kent, Herefordshire, and other counties, and he cannot but be struck with a demonstration of the immensely valuable improvements which may yet be made in very many parts of this kingdom. The now unimproved, unoccupied crown-lands, might alone, or even only a part of them, be rendered an inexhaustible source of unequalled wealth to the sovereign, of a vast increase of his subjects, and of happiness to all.

The common objection against inclosures have been so well refuted by many very able writers, and are daily invalidated by that most unerring test, experience, that it would be needless for us to recapitulate them here: we therefore shall only point out one farther essential advantage

tage attending this great improvement, which is, that it enables the farmer to act as is most agreeable to him in sowing when, and what, he pleases.

Every gentleman, whose estate is not yet inclosed, and who is consequently at liberty to choose the manner and means of doing it, will rationally begin with having a map of it drawn, that he may thereby be enabled to divide and portion it out, with the greater propriety and precision, so as to render it most pleasing to the eye, and most convenient to each farmer. If he has a place of residence upon it, he may make the whole become ornamental to that residence, by a judicious disposition of his hedges and plantations, as has been nobly done at Boughton, in Northamptonshire, by the late duke of Montagu, who, with a most refined taste, and truly benevolent mind, disdaining all the little and confined ornaments of a park, executed his fine improvements there in such a manner, as to render them pleasingly beneficial to all his neighbours, as well as to every person settled upon his land. Gubbins, in Hertfordshire, the seat of the late sir Jeremy Sambrook, is another charming example of elegance, though less extensive than the former.

Ha-ha walls, and pieces of water, with rails running across them, are an easy means of preserving a fenced level.

The farms should be so divided, that the dwelling of each tenant may be as contiguous to his land as convenience will admit of, to prevent length of carriage, and to facilitate his due attendance.

Small farms have always been observed to yield the greatest proportional rent, and small inclosures constantly produce the most plentiful crops.

Inclosures for arable lands should be larger than for pastures, that the soil may be kept dry, and the corn be well aired. For the manner of making inclosures, *see the article FENCE*.

ING, a common pasture or meadow.

INOCULATION, a very curious operation in gardening, otherwise called budding.

It is a kind of grafting practised in the summer months on several kinds of stone fruits, as peaches, nectarines, cherries, plumbs, apricots, &c. also upon oranges, jasmynes, and various other sorts of plants, which succeed better by this practice, than by the common method of grafting. The operation is performed in the following manner:

Being provided with a sharp knife, with a flat haft made for this purpose, as also with the cuttings of the tree intended to be propagated, make choice of a smooth part of the stock intended to be inoculated; if designed to be dwarf, five or six inches from the ground: but if a standard, it should be budded at the height of five and a half, or six feet; then, with your knife, make an horizontal cut across the rind of the stock, and from the middle of that cut make a slit downwards about two inches in length, being careful not to cut deeper than the thickness of the bark, lest the stock be wounded: then having the cutting ready, cut off the leaf from the bud, leaving the foot stalk remaining; cut the bud off lengthways, somewhat longer than the slit in the stock, with part of the wood to it; this done, with your knife slip the wood from the bark with a sudden jirk, and observe whether the eye of the bud is left or not, for those buds which lose their eyes in stripping are useless: then with the handle of the knife gently raise the bark on each side of the slit in the stock, and insert the bud therein, observing to place it smooth between the rind and the wood of the stock, cutting off that part of the rind of the bud which may happen to be too long for the slit made in the stock; so having exactly fitted the bud to the stock, tie them closely round with wetted strong bafs, taking care not to bind round the eye of the bud, which should be left open. In about three weeks or a month, the buds will require to be loosened of the bandage, which, if not done in time, will be very injurious to them, but not to be entirely divested of the binding, as it is not amiss to slightly tie them again, which will prevent the bark of the stock from flying open, as sometimes happens, whereby the bud is much injured, if not entirely destroyed.

The March following, the stock should be cut off about three inches above the place of inoculation, sloping it the contrary way to the bud; this length is of use to sustain the shoot to which proceeds from the bud, which otherwise might be blown out by strong winds; but the autumn following, it should be cut close just above the bud, that

the place of amputation may the more readily be barked over.

The time for inoculation, is from the middle of June to the latter end of August, according to the season and the forwardness of the different sorts of trees intended to be budded, which must be known by trying if the buds will separate from the wood easily. The first sort of fruit commonly inoculated, is the apricot, and the last the orange; although the orange is commonly budded in August, it is very proper to try the operation in July, and those stocks which miscarry may be budded the succeeding month, or even in September; but let it be done when it will, it is proper to place them in a gentle heat, giving them plenty of water, by which means there will be no reason to doubt of their success.

In performing this operation, it will be necessary to take the opportunity of moist cloudy weather, as the bud and stock will more readily unite, being more replete with juices than in hot dry weather, when the stock will perspire so fast, as to leave the buds destitute of moisture.

INOM, or *Innum Barley*, such barley as is sown the second crop after the ground is fallowed.

INSECT, a general name for the smaller kinds of animals.

With regard to the generation of insects, the world is now in general convinced, that they are not bred from corruption, but from eggs, though the contrary was believed by the ancients.

Malpighi, Swammerdam, and Redi, have abundantly confuted the doctrine of equivocal generation, as well as the chimerical transformation of the caterpillar into the butterfly, and have shewn, that all the members of the butterfly where inclosed under the nympha or skin of the caterpillar, as the parts of a plant are in the seed.

Insects take particular care to deposit their eggs or semen in such places where they may have a sufficient incubation, and where the young, when hatched, may have proper food till they can shift for themselves. Those whose food is in the water, lay their eggs there; those to whom flesh is a proper food, in flesh; and those to whom the fruits or leaves of vegetables are food, are accordingly deposited there, but constantly the same kind in the same tree. As for others that require a greater degree of warmth, they are provided by the parent with some place in or about the body of other animals, as the feathers of birds, hair of beasts, scales of fish, in the nose, in the flesh, nay some in the bowels of man, and other creatures. As for others, they make them nests, by digging into the earth, wood, &c. carrying in and sealing up provisions that serve for the production of their young, and for their food when produced.

There is observed in flies, butterflies, &c. a kind of glue of which the female fastens her eggs to the bearing buds of trees, &c. so as not to be hurt by rain or frost.

Mr. Andry, in his *Treatise De la Generation des Vers dans le Corps de l'Homme*, takes notice, that the ancients were mistaken in denying that insects breathed, on account of their wanting lungs; for modern observations convince us, that insects have a greater number of lungs than any other animals. They also thought that they had no blood, as many of them had no red liquor like ours; but it is not the colour, but the use of the liquor, that is to be regarded. They also believed that they had no hearts; whereas our microscopes now discover that, when insects have several lungs, they have also several hearts; and this in particular is observable in silk-worms, who have a continued chain of hearts from the head almost to the extremity of the tail; and, as is apparent from several insects, who give signs of life, long after they are divided into several parts.

Insects want no parts that are either necessary or convenient for their use, or to render them complete, in their kind. Some affirm that earth-worms, and those round-tailed worms, which are found in the intestines of men, horses, &c. as also snails, and horse-leeches, are hermaphrodites; but that such worms as become flies, and that silk-worms are not so, being of no sex, but nests full of real animals, which in time come out with wings.

Several sorts of insects do irreparable injury to the husbandman, though so very minute as hardly to be discovered.

Among others, a small kind of worm gets into the roots, chiefly of oats, and, working upwards, destroys all the inside of the plant, which perishes soon after. M. Duhamel suspects it to have been an insect of this kind that destroyed

vast quantities of wheat in the neighbourhood of Geneva, and of which M. de Chateaufieux sent him the following account: "Our wheat, says that illustrious husbandman, in the month of May 1755, sustained a loss which even that cultivated according to the New Husbandry did not escape. We found in it many little white worms, which afterwards became a chestnut colour. They pos't themselves between the blades, and eat the stems. They are usually found between the first joint and the roots. Every stalk which they attacked, grew no more, but became yellow and withered. The same misfortune befel us in the year 1732. These insects appeared about the middle of May, and made such havock that the crop was almost destroyed."

Mr. Lisle mentions, that on the 13th and 14th of June, in pulling up wheat in ear, and sow-thistles, he observed among the upper parts of the root of most of these plants, knots or clusters of grass-lice, or green locusts, as he calls them, which appeared whitish when they were but just come to their shape, and as yet under ground; and among most of these clusters he observed a fly at her incubation, very turgid, of a whitish matter; she then being blowing these insects. Her wings were black, and he thought her plainly the same as the locusts, excepting that it had wings. He did not find more than one fly at any one root.

We too often find, in our kitchen-gardens, a sort of vermin called vine-fretters. They fix upon the roots of leguminous plants, which afterwards gradually turn yellow and die. M. Tillet says he has observed the same insect in the roots of wheat.

The cuckow-spit, or spring-forth, as it is commonly termed, lodges itself principally in the joints of plants, seldom appears before the latter end of May, and is most common when rain has fallen after a series of dry weather. M. Poupert, in his account of this little creature, says, that as soon as it is out of its egg, it goes to a plant, which it touches with its fundament, and fastens there a white drop of liquor full of air; that it drops a second near the first, then a third, and so on till it covers itself all over with a scum or froth, which keeps it from the heat of the sun, or spiders that would suck it. But Mr. Lisle takes this liquid to be nothing but the nightly dew, which falls on the fork or joint of the plant, where the little insect works it into froth with its proboscis, as with a bellows. *See the article BUTTERFLY.*

INSTEP, a name given to that part of a horse's leg, which reaches from the ham to the pastern-joint.

INUNDATION, a flood, or the overflowing of lands by a large collection of water. For the manner of guarding against the bad effects of inundations, *see the article BANKS.*

JOBING, a term made use of by the farmers in the Midland counties, for buying and selling unnecessarily. Mr. Marshall, says "If a Midland farmer goes to a fair, he is ashamed to return without having done some "business:" he must either buy or sell, or he loses his credit as a marketman. Hence, probably, the quantity of business done at the Midland fairs, compared with those of other districts; where one third, or perhaps half, the stock is frequently driven out unsold: while, here, the whole fair may be said to be generally transferred."

JOURNEY. To travel by land, properly as much ground as might be passed over in a day; also a tract or extent of ground, way, or march.

Directions for preserving a Horse sound upon a Journey.

See that his shoes be not too strait, or press his feet, but be exactly shaped; and let him be shod some days before you begin a journey, that they may be settled to his feet.

Observe that he is furnished with a bitt proper for him, and by no means too heavy, which may incline him to carry low, or to rest upon the hand when he grows weary, which horsemen call, making use of his fifth leg.

The mouth of the bitt should rest upon his bars, about half a finger's breadth from his tusks, so as not to make him frumple his lips; the curb should rest in the hollow of his beard, a little above the chin; and if it gall him, you must defend the place with a piece of buff, or other soft leather.

Take notice that the saddle does not rest upon his withers, reins, or back-bone, and that one part of it does not press his back more than another.

Some riders gall a horse's sides below the saddle with

their stirrup-leathers, especially if he be lean; to hinder it you should fix a leather strap between the points of the fore and hind bows of the saddle, and make the stirrup-leather pass over them.

Begin your journey with short marches, especially if your horse has not been exercised for a long time; suffer him to stale as often as you find him inclined, and not only so, but invite him to it; but do not excite your mares to stale, because their vigour will be thereby diminished.

It is advisable to ride very softly, for a quarter or half an hour before you arrive at the inn, that the horse not being too warm, nor out of breath, when put into the stable, you may unbridle him; but if your business obliges you to put on sharply, you must then (the weather being warm) let him be walked in a man's hand, that he may cool by degrees; otherwise, if it be very cold, let him be covered with cloths, and walked up and down in some place free from wind; but in case you have not the convenience of a sheltered walk, stable him forthwith, and let his whole body be rubbed and dried with straw.

Although some people will have their horse's legs rubbed down with straw as soon as they are brought into the stable, thinking to supple them by that means; yet it is one of the greatest errors that can be committed, and produces no other effects than to draw down into the legs those humours that are always stirred up by the fatigue of the journey: not that the rubbing of horses legs is to be disallowed. on the contrary, we highly approve of it, only would not have it done at their first arrival, but when they are perfectly cooled.

Being come to your inn, as soon as your horse is partly dried, and ceases to beat in the flanks, let him be unbridled, his bitt washed, cleaned and wiped, and let him eat his hay at pleasure.

If your horse be very dry, and you have not given him water on the road, give him oats washed in good mild ale.

The dust and sand will sometimes so dry the tongues and mouths of horses, that they lose their appetites: in such case give them bran well moistened with water, to cool and refresh their mouths; or wash their mouths and tongues with a wet sponge, to oblige them to eat.

The foregoing directions are to be observed after moderate riding, but if you have rode excessive hard, unsaddle your horse, and scrape off the sweat with a sweating-knife, or scraper, holding it with both hands, and going always with the hair; then rub his head and ears with a large hair-cloth, wipe him also between the fore-legs and hind-legs; in the mean while, his body should be rubbed all over with straw, especially under his belly and beneath the saddle, till he is thoroughly dry.

That done, set on the saddle again, cover him, and if you have a warm place, let him be gently led up and down in it, for a quarter of an hour, but if not, let him dry where he stands.

Or you may unsaddle him immediately; scrape off the sweat; let the ostler take a little vinegar in his mouth and squirt it into the horse's; then rub his head, between the fore and hind-legs, and his whole body, till he is pretty dry; let him not drink till thoroughly cool and has eat a few oats; for many, by drinking too soon, have been spoiled. Set the saddle in the sun or by a fire in order to dry the pannels.

When horses are arrived in an inn, a man should, before they are unbridled, lift up their feet, to see whether they want any of their shoes, or if those they have, do not rest upon their sides, afterwards he should pick and clear them of the earth and gravel, which may be got betwixt their shoes and soles.

If you water them abroad, upon their return from the river, cause their feet to be stopped with cow-dung, which will ease the pain therein; and if it be in the evening, let the dung continue in their feet all night, to keep them soft and in good condition; but if your horse have brittle feet, it will be requisite to anoint the fore-feet, at the on-setting of the hoofs, with butter, oil, or hog's-grease, before you water him in the morning, and in dry weather they should be also greased at noon.

Many horses, as soon as unbridled, instead of eating, lay themselves down to rest, by the reason of the great pain they have in their feet, so that a man is apt to think them sick, but if he looks to their eyes, he will see they are lively and good, and if he offers them meat as they are lying,

lying, they will eat it very willingly; yet if he handles their feet he will find them extremely hot, which discovers their sufferings in that part.

You must therefore see if their shoes do not rest upon their soles, which is somewhat difficult to be known, without unshoeing them, but if you take off their shoes, then look to the inside of them, and you may perceive that those parts which rest upon the sole, are more smooth and shining than the others: in this case you are to pare their feet in those parts, and fix on their shoes again, anointing the hoofs, and stopping the soles with scalding hot black pitch or tar.

After a long day's journey, at night feel your horse's back, if it be pinched, galled or swelled, (if you do not immediately discover it, perhaps you may after supper) there is nothing better than to rub it with good brandy and the white of an egg. If the galls are between the legs, use the same remedy; but if the ostler rubs him well between the legs he will seldom be galled in that part.

In order to preserve horses after travel, take these few useful instructions. When you are arrived from a journey, immediately draw the two heel nails of the fore-feet; and, if it be a large shoe, then four: two or three days after you may bleed him in the neck, and feed him for ten or twelve days only with wet bran, without giving him any oats; but keep him well littered.

The reason why you are to draw the heel-nails is, because the heels are apt to swell, and if they are not thus eased, the shoes would press and straiten them too much: it is also adviseable to stop them with cow-dung for a-while, but do not take the shoes off, nor pare the feet, because the humours are drawn down by such means.

The following bath will be very serviceable for preserving your horse's legs: Take the dung of a cow or ox, and make it thin with vinegar, so as to be of the consistence of thick broth, and having added a handful of small salt, rub his fore-legs from the knees, and the hind-legs from the gambrels, chafing them well with and against the hair, that the remedy may sink in and stick to those parts, that they may be all covered over with it. Thus leave the horse till morning, not wetting his legs, but giving him his water that evening in a pail: next morning lead him to the river, or wash his legs in well-water, which is very good, and will keep them from swelling.

Those persons, who, to recover their horses feet, make a hole in them, which they fill with moistened cow-dung, and keep it in their fore-feet during the space of a month, do very ill, because, though the continual moisture that

issues from the dung, occasions the growing of the hoof, yet it dries and shrinks it so excessively when out of that place, that it splits and breaks like glass, and the foot immediately straitens.

For it is certain that cow-dung (contrary to the opinion of many people) spoils a horse's hoof; it does indeed moisten the sole, but dries up the hoof, which is of a different nature from it.

In order therefore to recover a horse's feet, instead of cow-dung, fill a hole with blue wet clay, and make him keep his fore-feet in it for a month.

For a horse that has been rid extremely hard, that there is danger of foundering, see an excellent remedy under the head *Foundering in the Feet*.

Most horses that are fatigued, or over-rid, and made lean by long journies, have their flanks altered without being purfy, especially vigorous horses that have worked too violently.

There is no better method to recover them, than to give each of them in the morning, half a pound of honey very well mingled with scalded bran, and when they readily eat the half pound, give them the next a whole one, and afterwards two pounds, every day continuing this course till your horses are empty, and purge kindly with it; but as soon as you perceive that their purging ceases, forbear to give them any more honey.

You may administer powder of liquorice in the scalded bran for a considerable time; and to cool their blood, it will not be improper to let them have three or four glisters: if their flanks do not recover, give them powder for purfing horses.

In case the horse be very lean, it is expedient to give him some wet bran, over and above his proportion of oats; and grafs is also extraordinarily beneficial if he be not purfing.

If it be a mare, put her to a horse, and if she never had a foal before it will enlarge her belly.

Sometimes excessive feeding may do horses more harm than good, by rendering them subject to the farcy.

You should therefore be cautious in giving them too great a quantity at a time, and take a little blood from him now and then.

When a horse begins to drink heartily, it is a certain sign that he will recover in a short time: but as to the method of giving him water during a journey, see HORSES.

JUG, a large drinking vessel, with a gibbous or swelling belly.

JUNET, earth-nut.

K.

KEEVE, a fat in which beer is worked or fermented.

KELL, a web, or kind of bag, in which insects are bred.

KID, a small faggot of under or brush-wood.

KIDDEROW, a place for keeping a sucking calf.

KIDNEYS, two pretty large glandulous bodies situated in the cavity of a horse's loins upon the two lowermost ribs.

Their use is to separate the urine, which is of great importance to the health and preservation of horses, they being liable to many diseases, which either take their origin from faulty kidneys, or have at least such symptoms, as plainly shew the kidneys to be more or less affected.

The signs of the kidneys being hurt or affected, are a

weakness of the back and loins, difficulty of staling, faintness, loss of appetite, and deadness in the eyes; the urine is thick, foul, and sometimes bloody, especially after a violent strain. A horse diseased in his kidneys can seldom back, that is, move strait backwards, without pain, which is visible as often as he is put to the trial: the same thing is observable indeed in horses, whose backs have been wrung and wrenched, but with this difference, that in the latter there is seldom any defect or alteration in the urine except that it is higher coloured.

Bleeding is the prime remedy, and that plentifully, in order to prevent inflammation; and the more so, if a fever attends a difficulty in staling, for then we may suspect the kidneys already inflamed. A rowel in the belly has been found useful, and the following balls may be given twice

twice or thrice a day, with a pint of marshmallow decoction, in which half an ounce of gum-arabic is dissolved, with an ounce of honey.

Take Lucatelli's balsam one ounce; spermaceti six drams; sal prunellæ half an ounce; mix into a ball with honey; if the urine is bloody, add half an ounce of Japan earth.

Should the fever continue, bleed largely, give emollient clysters, and the cooling, opening drink, till it abates.

If the urine passes with difficulty and pain, notwithstanding these means, give this ball, and repeat it twice or thrice a day, till the horse stales freer and without pain, his urine becomes of a right consistence, and is free from any purulent settlement.

Take balsam of capivi, or Strasbourg turpentine and Venice soap, of each one ounce; nitre six drams; myrrh powdered two drams: make into a ball with honey, and wash it down with the marshmallow decoction.

But if this method should not be successful, and the urine continues turbid, grows coffee-coloured or foetid, the horse losing his appetite and flesh, it is a sure sign of ulceration in the kidney; which if the above remedies do not soon remove, you may depend on it the horse will go into a consumption, and is incurable.

As a suppression of urine arises sometimes from an inflammation of the kidney; so at others, from a paralytic disorder, disabling them in their office of separating the urine from the blood: in this latter case the bladder is usually empty, so that a horse will make no motions to stale, and if he continues a few days in this condition, his body will swell to a great degree, breaking out in blotches all over, and death will soon close the scene.

If it arises from inflammation, bleed largely and treat the horse as above recommended; but if not, give stimulating clysters, and strong diuretics, such as the following balls, once in four hours; for if a horse stales not in thirty hours, his danger must be great.

Take juniper-berries powdered one ounce; sal prunellæ six drams; ætherial oil of turpentine half an ounce; camphor one dram; oil of juniper two drams: make into a ball with honey, and give after it three or four horns-full of the marshmallow decoction and honey.

Or,

Take squills powdered two or three drams; nitre half an ounce; or six drams: make into a ball with honey.

Or,

The following, which is more forcing, and should be given with caution.

Take cantharides well dried, from one scruple to half a dram; camphor dissolved in oil of almonds, from one dram to two; nitre and Venice soap, of each an ounce: mix into a ball with syrup of marshmallows.

When this last ball is given, the horse should be made to drink plenty of water, with gum-arabic dissolved in it; the following clyster may also be given at the same time:

Take of Barbadoes aloes two ounces; the same quantity of Venice turpentine, beat up with the yolks of two eggs; jallop powdered two drams; juniper and bay-berries, each a handful, bruised and boiled in two quarts of a decoction of mallows; strain off and mix by degrees with the above, to which add a pint of linseed-oil.

If the complaint is not recovered by these means, rub the horse's reins well with two parts of oil of turpentine, and one of oil of amber; and apply a poultice of garlic, horse-radish, mustard-seed, camphor, and green soap, spread on thick cloth, over them. Give the horse also two drams of calomel over night, and a moderate purge the next morning. These, perhaps, are the chief and

best remedies that can be given in this generally fatal disorder.

When the strangury in a horse does not arise from wind, or dung pressing on the neck of the bladder, the cause is from inflammation, or too long a retention of the urine. Such horses make frequent motions to stale, stand wide and straddling, are full, and have their flanks distended. In this case bleed largely; give the following drink, and repeat it every two hours for two or three times till the horse is relieved.

Take Venice turpentine broke with the yolk of an egg one ounce; nitre or sal prunellæ six drams; half a pint of sweet oil, and a pint of white wine.

If the drink should not have the desired effect, the diuretic ball above-mentioned may be given in the same manner, omitting the myrrh.

Give the horse plenty of the marshmallow decoction, in a quart of which dissolve an ounce of nitre and gum-arabic, and two of honey.

Horses subject to a diabetes, or profuse staling, if old, or of weak constitution, are seldom cured; they soon lose their flesh and appetite, grow feeble, their coat staling, and they die rotten. Of a young horse there are more hopes; but he must not be indulged with too much water, or moist food. Give him the following:

Take jesuits-bark four ounces; bistort and tormentil-root, of each two ounces: boil in two gallons of lime-water to the consumption of half, and give a pint three times a day.

Let the horse drink two or three quarts a day of lime-water; and if these medicines should not succeed, give a quart of strong allum posset, three or four times a day.

This method is proper also for a horse who stales blood; or the following balls may be given for that purpose, if the bleeding is profuse.

Take bole-armoniac one ounce; Japan earth half an ounce; roch allum two drams; elixir of vitriol one dram: make into a ball with conserve of roses, and give it every six hours.

As this disorder generally proceeds from too violent exercise, over-straining, &c. repeated bleedings in small quantities are absolutely necessary, till the mouths of the vessels close up. *Bartlett's Farriery, p. 159.*

KILN, a kind of stove for admitting heat, in order to dry any substance, as malt, hops, &c. See the articles MALT and HOPS.

KILN also signifies a fabric constructed for burning lime-stone, chalk, &c. into lime.

The kiln commonly used for this purpose is a large pit, generally round, and of a size proportioned to the quantities intended to be burnt. It is widest at the top, and narrower, by degrees, as it comes nearer the bottom. The inside of this pit is sometimes lined with a wall built of lime-stone; but more commonly, and more properly with brick: at the outside, near the bottom, is a hole, or door, by which the ashes are taken out; and above that, some have an iron-grate, which comes close to the wall round about: but others make an arch with stone, or large pieces of chalk; and upon this they lay a layer of stone, or of whatever else they burn in the kiln; upon this they place a layer of fuel, and so on, layer over layer, till the kiln is full; only observing that the outermost layer be always of the fuel, and not of chalk or stone. When the kiln is thus filled, fire is given at the hole underneath; and the lime is finished in a different time, according to the nature of the substance. That made of chalk is generally burnt in twenty-four hours; but stone often requires sixty hours. Ten bushels of sea-coal, or one hundred of faggots three feet long, will burn forty bushels of chalk, which will yield thirty bushels of unslacked lime. Where chalk is scarce, the chalk rubbish is often worked up into a kind of paste, with water, and made into a sort of bricks, which are dried in the air, and then burnt into lime in the common way: but this is not quite so good as that which is burnt from the chalk-stone.

The experience of late years has shown that it is more profitable

profitable to burn lime in kilns shaped like a hoghead; that is, small in circumference at the bottom, gradually wider towards the middle, and then contracting again upwards to the top. This kiln, as Mr. Lummis observes in his letter to the Edinburgh Society, published by Mr. Maxwell, should be made entirely within the surface of the ground, on the declivity of a little hill, where that situation can be had, so as to allow free access to the air-hole or surface. At the bottom, about a foot from the ground, are iron bars, placed horizontally across, to give the kiln a good draught, and upon these bars are laid, first small wood or furze, then small coals, then stones about the bigness of an egg, then another layer of fuel, and so on, increasing the size of the stones towards the middle of the kiln, where they may be as big as half a peck, and decreasing their size gradually up to the top, observing to lay the smallest nearest to the sides. The stones need not be broken so small for this kiln, as for those above ground; they will be burnt more truly without raw stones, or running into cinders; and not above half the quantity of fuel consumed in the common way, will be used in this.

The following method of constructing another kiln is thus particularly described in Mr. Maxwell's Collection:

"At bottom, the kiln must be three feet four inches wide; and at the height of two feet four inches, three feet six inches. At the depth of four feet and a half, it must be four feet and a half wide. A second slope is then made five feet and a half higher, at the end of which, the kiln, then ten feet deep, should be exactly ten feet wide within the walls. A third slope should heighten it to 14 feet, where it should be exactly 12 feet and a half wide, likewise, within the walls. From thence it is run up to the height of nineteen feet, when it should be rather less than fifteen feet wide. The slopes must be made as gradual as possible, and the inner surface of the kiln must be quite smooth, that its contents may fall down equally when the burnt stones are drawn out below. By extending a line from a pole fixed in the centre of the bottom or floor of the kiln to the sides, workmen will easily be guided in making the above-mentioned slopes. This kiln has four vents, opposite to one another, and no cross-irons whereupon to lay the coals and stones, they being supported by old timber, furze, broom, &c. above which the coals are laid: but if the kiln be built on the side of a hill, it can have but three vents. The first layer of stones above the vents should be closely jammed in, and rest against the sides of the wall. A kiln of the above dimensions will burn eighty bushels of lime-stones in a day; but it may be made larger, without altering these dimensions, by only adding two or three feet to the height, which will require strong walls. This addition to the height need not be sloped, but may be made perpendicular.

The late earl of Stair had a kiln at New Liston, and others in Galloway, built in the shape of an egg, opened a little at both ends, and set upon the smallest. This kiln answered exceedingly well, and besides lime-stone, burnt any kind of earth that was thrown into it.

Kilns thus built, swelling at or about the middle, and contracting again at the top, reverberate more strongly, and make a more intense heat, than those which grow wider and wider, and are not contracted.

When the kiln is filled, or finished as it is commonly termed, it should be covered over with sods of strong turf, to keep the heat as intense as possible, and hinder the wind from blowing the fire at the top, or rain from abating or

extinguishing it. The stones must be broke in pieces before they are thrown into the kiln; otherwise the air contained in their cavities, being expanded by the heat, will often make them fly with such violence as to damage the kiln. For this reason they should be broken smaller for kilns that are above ground, than for those which are underneath. The saving of this labour, and of near half the quantity of fuel, renders these last greatly preferable.

Lime is made of chalk, or of any stone that is not too cold, or sandy, as freestone and the like. All the soft stones that are of a tolerably close texture, will burn to good lime, as will also marble, slate, sea-shells, corals, and flints; but this last kind of stone is more difficult to be burnt into lime than the others, except in a reverberatory kiln, because it is apt to run to glass. The hardest, firmest, and whitest stones make the best lime; and when it is made of chalk, that which is formed of the hardest, stony kind, is much better than that which is made from the soft; but the harder the stones are, the more fire it requires to burn them. Both sorts may be burnt with wood, coals, turf, furze, or fern, which make a very fierce fire.

These kilns seem to be intended for burning only one kiln full at a time; but where large quantities of lime are wanted, perpetual kilns, that is, kilns where the fire is kept constantly burning, are constructed on nearly the same principles. Here the iron bars at the bottom are absolutely necessary, in order to take out the lime as soon as it is burnt. When stone-lime, which requires the most violent fire, is burnt in these kilns, vents are made near the bottom to be opened occasionally, according as the wind fits, that a stronger current of air may quicken the fire, and thereby give it the more power. *See the article LIME.*

KILN-ASHES, the ashes made in kilns where wood, straw, furz, &c. are burnt. These ashes are a good manure for almost any kind of soil. In the west of England, the farmers sift them over their corn and grass; but this must not be done in windy weather, because they are so very light, that they would easily be blown away. They succeed best when laid on just before rain or snow.

KINNEL, a powdering tub.

KIT, a milking-pail, in the form of a churn, with two ears and a cover.

KITES, hawks, and other birds of prey, wait for chickens, pigeons, pheasants; and upon which account it is necessary that the countryman be constantly furnished with a good fowling-piece to destroy them; or steep the entrails of pigs, fowls, or rabbits in the lees of wine, into which you have infused a quantity of nux vomica, and throw a bait where the kites come in the evening, or early in the morning. This will intoxicate them so, that a person waiting near the spot, may easily take them.

To recover them so as to tame them.

When they are caught during the fit of intoxication, pour a little salad oil down their throats, and rub their heads with strong white wine vinegar; and the cure will be speedily effected.

KNAPWEED, the same with blue-bottle. *See BLUE-BOTTLE.*

KNOT-GRASS, the same with couch-grass. *See COUCH-GRASS.*

KNOLL, a little round hill.

KNOLLS, a term used in some counties of England to signify turneps.

L.

LABOURER. See SERVANTS.

LACTARY, a milk-house.

LADIES-SMOCK, *Cuckoo flower*, or *Canterbury-bells*, a perennial weed, and common in pasture grounds. The stalk is upright, round, and smooth. The leaves are winged, with the lobes of the lower ones roundish, and of those on the stalk oblong. The flowers are large, handsome, and white, or purplish, consisting of four obtuse veined petals. The seeds are contained in erect compressed pods, about an inch in length, divided into two cells, which, when ripe, burst with a touch, and throw out their seeds to a considerable distance.

LAIRE. See LAYER.

LAMB, the young of the sheep-kind. See the article SHEEP.

LAMENESS, in horses. See the article STRAINS.

LAMPAS, an excrescence in the roof of a horse's mouth, which is sometimes so luxuriant, that it grows about the teeth, and hinders his feeding.

The cure consists in lightly cauterizing the flesh with a hot iron, taking care that it does not penetrate too deep, so as to scale off the thin bone that lies under the upper bars: the part may then be anointed with burnt allum and honey, which is proper for most sores in the mouth. *Bartley's Farriery*, p. 282.

LAND. See the article GROUND and SOIL.

LARCH-TREE, a genus of trees, whose leaves, which are long and narrow, are produced out of little tubercles, in form of a painter's pencil: the cones are produced at remote distances from the male flowers on the same tree: the male flowers are very like small cones at their first appearance, but afterwards stretched out in length.

These trees are propagated by seeds, which should be sown in the beginning of March, upon a bed of light soil, exposed only to the morning sun: or otherwise they may be sown in pots or boxes of light earth, and placed near a hedge, where they may have the morning sun only. The seed should be covered about half an inch thick with fine light earth, and in very dry weather should be gently refreshed with water. In about six weeks, if your seeds were good, your plants will come up, at which time you should carefully guard them against the rapacious birds, which would otherwise pull off the heads of the plants, as they thrust themselves out of the ground with their covers on them: and observe to refresh them with water in dry weather, especially if they are sown in pots or boxes; also to keep them clear from weeds, which, if suffered to grow among the young plants, will soon destroy them: nor should they be too much exposed to the sun, or strong winds, both which are very injurious to these plants while they are young: but in October you should, if they are in boxes or pots, remove them into a situation where they may be defended from sharp winds, which are sometimes hurtful to them, while young; but afterwards they will endure the severest weather of our climate.

These trees are very proper for the sides of barren hills, where few other sorts will thrive so well: nor is this tree very delicate in its soil, but will grow much better on poor, strong, stony land, than in rich ground; and, during the summer, they appear very beautiful; but in autumn they cast their leaves, whereby some people have been deceived, by supposing them dead, and have destroyed them.

From the wounded bark of this tree exudes the purest Venice turpentine; and on the body and branches of it grows the agaric, which is a drug used in medicine.

Mr. Young, in his *Annals of Agriculture*, vol. V. speaks of the larch tree to the following effect. "Larixwood is possessed of so many valuable qualities, that to enumerate the whole would appear an extravagant hyperbole. It is known to resist water, without rotting, almost for ever. The piles of larix timber on which the houses of Venice

were built many hundred years ago, when examined, are still found as fresh as when first put in. And I have been told, stakes of it have been tried in the decoys of Lincolnshire, which, between wind and water, have already outworn two or three sets of oak stakes, and do not yet discover any symptoms of decay. It is also known to possess the valuable quality of neither shrinking nor warping, when put into work; nor is it liable to be pierced by worms in our climate, as many of the paintings of Raphael Urban, which are done on this wood, and are still perfectly entire, sufficiently prove.

"Experiments have not yet ascertained whether it will resist the sea-worm in tropical climates, like Bermuda cedar; but there is reason to think it would, as in many of its other properties, it resembles that wood very much. Along with these valuable properties, it is known to be one of the quickest growing trees in this climate, remarkably hardy, and extremely beautiful when growing. It is, besides, much more easily reared than the oak, and could be spread over a great extent of mountains, if sufficiently bare of herbage, at next to no expence, by the natural shedding of its seeds, like birch or fir in soils that favour them, merely by keeping out cattle from those fields in which small clumps of this kind of wood had been planted some years before. In this way very extensive tracts in the condition described might be entirely filled with this valuable timber. The uses to which it might be applied are innumerable. It would be valuable not only for ship-plank; but even crooked timbers might be obtained by using a little art when young to bend it, as the Bermudians do their cedar; for flood-gates in navigable canals and wet-docks, it would exceed every thing that can be obtained in this climate. For barrel staves it would be inimitable, and would enable us to furnish that article as cheap as in any other nation whatever: and in building it would answer all the purposes to which fir is now applied, being much stronger and more durable than that wood. And when it is also adverted to, that it is next to incombustible, the reader will not think it strange that I in this manner so strongly recommend it to the attention of my countrymen, particularly those in the most rugged and barren districts: for, in such situations, it would be easy to shew, that at a very trifling charge, they might, in a short period of years, bring their estates to a hundred times the value they bear at present, or ever can be made to bear by any other kind of improvement. This would be a much more eligible plan of bettering their fortune than that of trying to squeeze, with difficulty, from a poor people, a raised rent for a subject that does not admit of proportionable improvement."

LASK, LAX, or LOOSENESS, [*in Horses*] is a distemper occasioned by such a weakness of the stomach, that their food passes through their guts without any alteration, which is a very dangerous case, and frequently fatal to them. It also sometimes proceeds from the corruption of humours, either collected in the stomach, or thrown upon it from other parts.

The external causes are, eating too much provender, feeding upon mouldy or rotten hay, frozen grass, rye, straw, and other unwholesome fodder, drinking very cold water, or immediately after the eating of a great quantity of oats, immoderate fatigue, excessive fatness, and sometimes want of exercise.

If the excrements voided, boil and work upon the ground, it is a sign that the distemper proceeds from overheated choler, which is seldom dangerous; nay it is sometimes profitable.

Again, if the ordure be white, it is a sign of crude, cold humours; if watery, it betokens a great weakness in the stomach.

Lasks occasioned by drinking cold water in summer, or melted

melted snow, or by eating tender grafs, or other loosening things, are not to be regarded; but such as proceed without any manifest outward cause, are not by any means to be neglected.

For the cure. If the excrements appear mixed with small pieces or scrapings of the guts, you ought immediately to endeavour to prevent a deadly ulcer in those parts, by giving him two or three times a day a pint of cooling softening decoction, made as follows: viz. two ounces of barley, two ounces of marsh-mallow roots, and one ounce of the powder of sal prunella, boiled in three quarts of water to one quart.

If the distemper is caused by phlegm, you may make use of cordial powders or pills, and other hot medicines proper for strengthening the stomach and relaxed parts.

Sometimes a lax is a reasonable effort of nature, to free itself from a troublesome load of humours; but if it continues longer than three days, with loss of appetite, it ought to be checked, for horses are sometimes foundered by its long continuance.

In this case, give the horse for his food, bran moistened with claret, or barley parched and ground, and the best hay; but oats are in no wise proper.

A horse is in the best order that only dungs once, or at the most twice, in ten miles riding. Young and fiery horses are often very lax; but this weakness generally leaves them by the time they are seven or eight years old, if they have been properly fed and but gently exercised. The fiery sort sometimes continue to purge after any extraordinary exercise, for their digestive powers are, for the most part, but weak; and also eat so speedily, that they swallow their oats almost whole, and eject them in the same state.

When a purging is habitual, or happens by accident, until the horse seems to lose strength or flesh, or both, it is not necessary to give him any astringent medicines, as the discharge may be only a salutary effort of nature to throw off what is either redundant or offensive; a gentle purge may be given, and a few mashies of bran; which, perhaps, by assisting nature, may perfect a cure: but if the disease continues, and the horse loses flesh, grows dispirited and feeble, recourse must be had to astringents, when the dung is like that of a cow, but the vigour of the horse not impaired, he is said to have a lax: but when the strength and flesh fails he is said to have a scouring or purging.

When a scouring comes on at the latter end of any obstinate and tedious disease, as low, putrid fevers, farcy, &c. they are usually the forerunners of death, particularly if they are accompanied with a disagreeable discharge at the same time from the nose.

If the scouring proceeds from cold, and there is some degree of fever, according to the strength of the horse and the violence of the heat, bleed; then give the following:

Take of rhubarb, half an ounce, or six drachms; lenitive electuary, two ounces: mix, and make a ball.

Repeat this, every two or three days, until the fever abates: and betwixt the days of giving the rhubarb, give the following astringent medicine once a day.

Astringent Decoction.

Take oak bark, grossly powdered; boil it in a pint of water to the consumption of one third; then pour off the liquor for one dose.

Except the fever and purging increase together, great care should be taken not to check the purging, lest the fever be increased thereby.

If little or no fever attends, after bleeding, give the following solutive ball:

Take of aloes half an ounce; diapente, one ounce; treacle enough to make a ball: repeat this once a week, and if there is much griping and distention from wind, the restringent glyster will be necessary.

It may be proper to remind the reader, that in these complaints, glysters should be small in quantity; and if the disease is violent, they should be repeated as often as they come away. If there is great pain, forty drops of liquid laudanum may be added to one of the glysters, and repeated as the urgency thereof requires.

If the scouring still continues without relief, give two drachms of cerated glass of antimony, mixed with one ounce of diacodium, or two ounces of cordial balls.

Alum, Armenian bole, or other astringent and absorbent medicines, are given to one ounce, once or twice a day, but usually one or two doses will answer the end.

If the cause is a weak digestion, which is known by the food passing nearly in the same state in which the stomach received it; the dung being very soft and pale; the appetite small, and the horse very lean: beside gentle exercise and dry food, such as the best hay, beans in larger quantities than are usually given, and those so moistened that the horse need not drink much, give the following stomach purge, and repeat it as occasion may require:

Take of aloes, half an ounce: cream of tartar and myrrh, each half an ounce; treacle, enough to make a ball; and on the days in which this purge is not operating, give the following:

Stomach Drink.

Take of oak-bark, bruised, half a pound; Gentian root sliced, one pound; ginger, bruised, two ounces; infuse them in a gallon of ale three or four days; and give half or three quarters of a pint every night and morning.

When a viscid matter, obstructing the mouths of the lacteals, gives rise to this disorder, a summer's grafs, or, which is still better, the salt marsh, will effect a cure: where these cannot be obtained, the stomach purge before directed may be given once a week.

In any of the above cases, where there is a discharge of sharp, slimy matter, with severe griping, avoid oily and greasy things, but give the following in glysters, viz. Tripe-liquor, or very thin starch; either of these may be given to three or four pints at a time, and liquid laudanum, to the quantity of forty or sixty drops, may be added to one of the glysters, to moderate the pains, and repeated as may seem needful.

When blood appears with the excrement, it is called the bloody-flux: in which case, if there is great pain, and frequent motions for discharge, there is also a great danger. In this case give frequent glysters of tripe-broth, or thin starch, with thirty or forty drops of liquid laudanum in each, until the pain is abated in some measure; and give the same medicines as above directed for the more obstinate scourings, particularly the ball made with cerated glass of antimony, and cordial ball. For common drink give the following:

Boil a pound of burnt hartshorn in ten pints of water to a gallon; at the latter end of the boiling, add to it four ounces of gum arabic; continually stirring until the gum is dissolved: then remove the whole from the fire.

LASSITUDE, or weariness in horses, may proceed either from heat or cold; either when he has a retention of urine, has drank after being heated, or has been put to his utmost at once after long rest; the remedy for which is, rest. You may also give him hog's suet mixed with wine.

If the lassitude proceeds from cold, or be in cold weather, make use of fomentations, and anoint his head and back-bone with ointment, in hot water or warm wine.

If he has retained his urine, use the same medicines, or rub his head and reins with hot oil, mixed with hog's grease or hog's blood, and give it him to drink with wine.

LATH, a long, thin, and narrow slip of wood, nailed to the rafters of a roof or ceiling, in order to sustain the covering.

These are distinguished into three kinds, according to the different kinds of wood of which they are made, viz. heart of oak, sap laths, and deal lath; of which the two last are used for ceilings and partitions, and the first for tiling only.

Laths are also distinguished according to their length; into five feet, four feet, and three feet laths; though the statute allows but of two lengths, those of five, and those of three feet, each of which ought to be an inch and a half in breadth, and half an inch in thickness; but they are commonly less.

LATH-BRICKS, bricks much longer than ordinary, used instead

instead of laths, for drying malt; for which purpose they are extremely proper, as not being liable to catch fire, and retaining the heat much longer than those of wood; so that a very small fire will serve after they are once heated.

LATHE, a word used in some counties in England, to signify a barn.

LEAF, a part of a plant, commonly very thin and flat, growing in the spring, and falling off in the autumn.

Leaves are the ornament of the twigs, and consist of a very glutinous matter, being furnished every where with veins and nerves. Their office is to subtilize the nourishing sap, and convey it to the little buds; and likewise they serve to cover the flowers and fruits with their shade, and keep them from other inconveniences; they are to trees what hair is to the human body.

Dr. Grew observes, that the fibres of leaves consist of two general kinds of vessels, namely, for sap, and for air; and are ramified out of greater into less, as veins and arteries are in animals.

Mr. Frederick, of Augsbourg, a celebrated gardener, took from the tree a leaf of the opuntia or Indian fig-tree; and setting it in the earth, it immediately took root, and produced blossoms and fruit.

The distinction of leaves, made by those who have written on botany, are the following:

A simple leaf is that which is not divided to the middle.

A compound leaf is divided into several parts, each resembling a simple leaf, as in liquorice, &c.

A digitated leaf is a compound leaf divided into several parts, all of which meet together at the tail, as in the hemp, black hellebore, &c.

A trifoliated leaf is a digitated leaf, consisting of three fingers, as the trefoil, &c.

A quinquelfoliated leaf is a digitated leaf, consisting of five fingers, as in the quinquelfolium.

A pennated leaf is a compound leaf divided into several parts, each of which is called a lobe, placed along the middle rib, either alternately, or by pairs. When the middle rib is terminated by an odd lobe, it is said to be unequally pennated, as in the goats rue, &c. and equally pennated, when it is not terminated by an odd lobe, as in the cassia; when the lobes are all nearly of the same form and bigness, it is called an uniform pennated leaf, as in the liquorice; when they are not so, it is said to be difform, as in the agrimonia.

A winged leaf is, as it were, divided into several pennated leaves, as in the orobus, &c.

A ramose leaf is that which is still farther divided than the winged leaf, as in the osmund royal, female fern, &c.

An entire leaf or lobe is that which has no division on its edges, as in the apple-tree, &c.

A sinuated leaf is that which is cut about the edges into several long segments, as in common mallows.

A serrated leaf is that which is cut about the edges into several acute segments, resembling the teeth of a saw, as in the nettle, &c.

A crenated leaf is that which is cut about the edges into several obtuse segments, as in the betony, &c.

A lacinated or jagged leaf is that which is cut about the edges into several pretty deep portions, in an irregular manner, as in the horned poppy, &c.

If the surface of the leaves are altered, by reversing the branches of trees on which they grow, the plants are stopped in their growth, until the footstalks are turned, and the leaves recover their former position. This shews how necessary it is to support all those weak shoots of plants, which are naturally disposed for upright growth, which either twine about the neighbouring trees for support, or that put out clasps, by which they take hold of whatever trees or plants grow near them, and are thereby supported; and, on the contrary, how absurd is that practice of tying up the shoots of those plants which are naturally disposed to trail upon the ground; for in both these cases nature is reversed, and consequently the growth of both sorts of plants is greatly retarded.

This is one of the great functions for which the leaves of trees and plants are designed; but besides this, there are others of equal importance to the well-being of plants and fruits: the first is, that of the footstalks and leaves nourishing and preparing the buds of the future shoots, which are always formed at the base of those footstalks, and during the continuance of the leaves in perfect health, these buds increase in their magnitude; and, in the deci-

duous trees, are brought to maturity before the footstalks separate from the buds in autumn; but if by accident the leaves are blighted, or if the entire surface of the leaves are cut off, and the footstalks are left remaining, the buds will decay for want of that proper nourishment which is conveyed to them from the leaves; so that whenever trees are divested of their leaves, or those leaves are cut, or otherwise impaired, though it may in either case happen when the buds may be nearly formed, yet if it is before the footstalks separate naturally from their branches, the future shoots will be weakened in proportion to the time when this is done; therefore from all the experiments which have been made in order to know how serviceable the leaves of trees and plants are to their well-being, it has been found, that when the plants have been divested of their leaves, or their leaves have been eaten or cut, during their growth, the plants have been remarkably weakened thereby. This should teach us not to pull or cut off the leaves of trees, or plants, on any account, while they retain their verdure, and are in health; and this shews how absurd that common practice is, of feeding down wheat in the winter and spring with sheep; for by so doing, the stalks are rendered very weak, and the ears are in proportion shorter; nor are the grains of corn so plump and well nourished, as that which is not fed down upon the same ground: this is a fact which we can assert from many years experience. It is very evident, that grass which is often mowed, the blades will be rendered finer in proportion to the frequency of mowing it, yet the species of grass is the same with that on the richest pastures; so that although this may be a desirable thing for lawns, &c. in gardens, yet where regard is had to the produce, this should be avoided.

Another principal use of the leaves, is to throw off by transpiration what is unnecessary to the growth of the plants, answering to the discharge made by sweat in animal bodies; for as plants receive and transpire much more, in equal time, than large animals, so it appears how necessary the leaves are to preserve the plants in perfect health; for it has been found by the most exact calculation, made from repeated experiments, that a plant of the sun-flower receives and perspires, in twenty-four hours, seventeen times more than a man.

Mr. Young, in his *Annals of Agriculture*, vol. VII. recommends the leaves of trees as food for sheep. He says, that at Languedoc, "These animals have scarcely any other food from November to April, than the leaves of trees, preserved for that purpose; the broom is therefore the only fresh food they have; they eat it with great avidity, and prefer it to all other plants: they are, however, subject in consequence of living entirely upon it, to an inflammation in the urinary passage, by which sometimes the fifth of a flock is destroyed, but this is very easily prevented by a proper change of food."

We shall beg leave to mention a few, out of the many experiments which have been made by M. Bonnet, of Geneva, to prove that most leaves imbibed the moisture of the air on their under surface, and not from their upper; they are as follow:

He gathered the leaves of sixteen sorts of herbaceous plants when fully grown: of each he put several leaves upon the surface of water in glass vases; some were posited with their upper surface, and others with their under surface upon the water; these were adjusted exactly to the surface of the water, with great care not to let any moisture reach their opposite surfaces, and the same care was taken to prevent their footstalks from receiving any moisture. The glasses in which these leaves were thus placed, were kept in a closet, where the air was very temperate; and as the water in the glasses evaporated, there was, from time to time, a supply of fresh, which was added with a syringe, so that the leaves were not disturbed. The leaves were taken from the following plants: the plaintain, the mullein, the wake-robin, the great mallow, the nettle, the marvel of Peru, the kidney-bean, the sun-flower, the cabbage, the baum, the cock's-comb, the purple leaved amaranth, spinach, and the smaller mallow.

Six of these sorts he found continued green a long time, and these were with different surfaces upon the water: they were of the following sorts: the wake-robin, the kidney-bean, the sun-flower, the cabbage, spinach, and the small mallow; among the others the following sorts were found to draw the moisture better with their upper than with their under surface: the plaintain, the mullein, the great

great mallow, the nettle, the cock's-comb, and the purple amaranth.

The leaves of the nettle, whose under surfaces were placed upon the water, were decayed in three weeks; whereas those whose upper surfaces touched the water, lasted three weeks.

The leaves of the mullein, whose under surfaces were next the water, did not continue fresh more than five or six days, whereas those whose upper surfaces were next the water, lasted five weeks.

The leaves of the purple amaranth, whose upper surfaces were next the water, continued fresh three months; whereas those whose under surfaces touched the fluid, were decayed in a week.

The leaves of the marvel of Peru and the baum appeared to have the advantage, whose under surfaces were next the water.

The leaves of the wake-robin, and of the cock's-comb, whose footstalks only were put in the water, continued fresh a longer time than those which were placed with either surface upon the water.

The leaves of the great mallow, the nettle, the sun-flower, the marvel of Peru, and the spinach, whose footstalks were plunged into the water, continued fresh a shorter time than those which had either of their surfaces upon the water.

The leaves of the mullein, plaintain, and amaranth, which received the water at their footstalks, continued fresh much longer than those whose under surfaces touched the water.

It is not difficult to explain the reason of this fact; for the orifices of the sap-vessels in the footstalks are much larger than those of either surface, so that the water insinuates itself in greater quantities, and with more ease in the first than by the second way.

After this the same gentleman made experiments on the leaves of sixteen sorts of trees and shrubs, of the following sorts: the lilac, the pear-tree, the vine, the aspin, the laurel, the cherry-tree, the plum-tree, the horse-chestnut, the white mulberry, the lime-tree, the poplar, the apricot, the walnut, the filbert, the oak, and the creeper.

Among these species he found, that the lilac, and the aspin, imbibed the water equally with either their upper or under surface; but in all the other sorts, the under surfaces imbibed it in much greater quantities than the upper. The difference was very remarkable in the leaves of the white mulberry, for those whose upper surfaces were laid upon the water, faded in five days; whereas the others, whose under surfaces were next the water, preserved their verdure near six months.

The vine, the poplar, and the walnut afforded very remarkable instances, how little disposed the upper surfaces of the leaves of ligneous plants are to imbibe the moisture: for the leaves of these three sorts, whose upper surfaces were applied to the water, decayed almost as soon as those which had no nourishment.

In all the experiments made by this curious gentleman upon the various leaves of trees and herbs, it is remarkable that all those leaves, which imbibed their moisture by their upper surface, were such as had that surface covered over with hairs or down: and, on the contrary, where the under surface was garnished with either hairs or down, the nourishment was imbibed by that surface. He also mentions many experiments made by himself, and also by M. Duhamel de Monceau, of the Royal Academy of Sciences at Paris, in rubbing the leaves over with varnish, oil, wax, and honey, to see the effect of these upon various leaves, some of which were rubbed over on both surfaces, others only upon one; some only a part of the surfaces, others the edges of the leaves were rubbed over, and in some only the footstalks of the leaves. They likewise anointed the trunks of some trees and shrubs, leaving the leaves and branches in their natural state.

The result of these experiments was, that where the leaves were covered with varnish on both sides, they presently decayed; and where they were anointed with other things, the leaves continued a shorter time than others, in proportion as the things were more penetrating; and where one surface only was anointed, they continued much longer than those which were anointed on both: and where the pedicle alone was anointed, they continued still longer: but the anointing of the trunks made no sensible alteration, except in very hot weather; when they were both of opi-

nion the anointing them were of service, by hindering the too great transpiration, which tend to weaken the trees: for they observed, that those trees which were varnished, suffered less from the violent heats, than the trees which were left in their natural state.

M. Bonnet also observed, that the tender parts of the leaves which were varnished were destroyed by it, and the tough fibres only left remaining.

We may therefore reasonably conclude, that one great use of leaves is what has been long suspected by many, viz. to perform, in some measure, the same office for the support of vegetable life, as the lungs of animals do for the support of animal life: plants, very probably, drawing through their leaves, some part of their nourishment from the air. *Miller's Gard. Diet.*

LEAP, or *Lip*, half a bushel.

LEASE, *Ley*, *Lay*, or *Ley*, implies grassy ground, meadow ground or unploughed ground, kept for cattle.

LEASE also signifies the letting of lands, tenements, &c. unto another for life; a term of years, under a reserved rent.

LEES, the more gross and ponderous parts of liquors, which, being separated by fermentation, fall to the bottom.

The lees of wine, beer, ale, and oil, are excellent manures.

LEET, a little court held within a manor, and called the king's court, on account that its authority to punish offences originally belonged to the crown, and from thence descended to inferior persons.

LEGS OF A HORSE should have a due proportion of their length to that of the body: the fore-legs are subject to many infirmities, as being the parts that suffer most, and are also commonly the smallest and weakest.

There are several marks of bad legs, viz. if they appear altogether straight, or as if they were all of one piece.

A horse is said to be straight upon his members, when from the knee to the fore part of the coronet, the knees, shank and coronet, descend in a straight or plumb-line, and that the pastern-joint appears more, or at least as much advanced as the rest of the leg; such legs are like those of a goat, making a horse apt to stumble and fall; so that in time the pastern is thrust quite forward, out of its place, and the horse becomes lame.

Horses which are straight upon their members, are quite contrary to those that are long jointed; that is, whose pasterns are so long and flexible, that the horse in walking almost touches the ground with them.

This is a greater imperfection than the former, because some remedy may be applied to them, but there can be none for this; besides, it is a sign of little or no strength, and such horses are not fit for much fatigue or toil.

Some horses, though they be long-jointed, yet do not bend their pasterns in walking, being somewhat long; yet if they are not too flexible, such a horse will gallop and run with a great deal more ease to his rider, than if he were short jointed.

These are the only horses for persons of quality, who seek after their own ease and pleasure; and indeed those horses may be compared to coaches with springs, which render them infinitely more easy than those without them.

LEGS in a straight line is an imperfection in a horse, where his legs from the knee to the coronet, appear in a straight line as the horse stands with them in their natural position.

The remedy is shoeing; in doing which the heels must be taken down almost to the quick, without hollowing the quarters; and if, when this has been done, the leg does not fall back enough, but that the horse still carries his pastern-joint too far forward, then the shoe must be so made as to go beyond or exceed the toe, about the breadth of half a finger; and also it must be thicker in that than in any other part: and in the mean time, anoint the back sinews of his legs with the ointment of Montpellier; and these things will reduce them to their proper position.

Of the four legs, the two before have several parts, each of which has a peculiar name; so that by the name of fore-leg, we commonly understand that part of the fore-quarters that extends from the hough to the pastern-joint, and call it the shank. The part that corresponds with it in the hinder quarters we call the inflep.

But in common discourse, we confound the fore and hind quarters, and without any distinction, say, the fore leg of a horse.

A horse is said to want the fifth leg, when he is tired, and, bearing upon the bridle, lies heavy on the horseman's hand.

LENTIL, or *bitter Vetch*, the name of a plant of the vetch or tare kind, cultivated in some parts of England as fodder for cattle.

Lentils grow to a foot and a half high, with stalks and leaves like those of tares, but smaller; and like them they bear their seeds, generally three or four in little pods. These seeds are round, hard, smooth, and flat, but thicker at the sides. There are two sorts of lentils, the white and yellow; but the latter affords the greater quantity of fodder.

The seeds of this plant are commonly sown in March, where the land is dry, but in moist ground the time is in April. The usual quantity of seed allowed to an acre of land is from one bushel and a half to two bushels. If these are sown in drills in the same manner as pease, they will succeed better, than when they are sown broad-cast. The drills should be a foot and a half asunder, to allow room for the hoe to clean the ground between them; for if the weeds are permitted to grow among them, they will get above the lentils, and starve them. *Miller's Gard. Dict.*

LIGS, in a horse, are little pushes, wheals or bladders, within the lips of a horse, and are cured by bruising wormwood and skirwort in a mortar, with a little honey, to anoint the sores with.

LIME, a soft friable substance, obtained by calcining or burning stones, shells, and the like.

The most certain way to know whether any sort of stone be fit for making lime, is to drop upon it a little aquafortis, spirit of sea-salt, or oil of vitriol. All stones on which the above, or any other strong acid effervesces or rises in bubbles, are lime stones, or will burn to lime; and the stronger the effervescence is, the fitter they are for that purpose. All country gentlemen should keep some such spirit by them, to try the nature of the stones that may be found on their estates.

All lime is a very good manure, but that made of stone is much better than what is made of chalk. It makes the greatest improvement upon light sandy soils, or upon a dry gravel; wet and cold gravel is less benefited by it, and cold clay the least of all. The common allowance is a bushel to a pole square, or a hundred and sixty bushels to an acre. Mr. Lummis laid after the rate of three hundred bushels on an acre, and found it answer extremely well: but that was upon a strong clay. His method of using it, as communicated to the Edinburgh Society, and the result, he says, of what he had experienced to be best, is as follows:

"In the month of October, he lays together three or four of the largest stones (burnt into lime) on the sward or turf of a strong clay ground: or as many of the small stones as are equal to the large ones, so that seventy or eighty bolls (two hundred and eighty, or three hundred and twenty bushels) may complete an acre. If rain falls, it melts immediately; if not, it will melt and flake in forty-eight hours, or less, according to the moisture of the air. He then spreads it directly, leaving no part of it upon the spot where the stones were laid. This done, he lets it lie twelve months, or till the month of November after the October twelve months, when he ploughs it in, and lets it remain in that state all the winter, during which frosts and rains mellow and prepare the ground for the next spring ploughing, and render it fit for barley. He prefers this method to laying the lime on in powder, because, in this last way, it is apt to be blown about with the wind, to the great detriment of both men and horses, such as spoiling the men's eyes, hair, and cloaths, and the eyes and hair of the horses, making their coats look dry and ugly, besides losing much of the lime.

"The lime laid in the month of October, as above directed, on a strong arable land, which has been some years under grass, and continuing spread for about twelve months before it be ploughed in, has been found so to alter the grass to a fine natural clover, that, by feeding of sheep or black cattle upon it, it has paid the whole charge the first year by the grass, and cattle will choose rather to feed on this ground than any other, and grow fatter. If the ground be loose and open, it may be ploughed in the ensuing March, if limed in October. In either way, it so far melliorates the sward, and the soil, that the best of crops may

be expected for three or four years; and by laying some dung upon it the 4th or 5th year, two or three crops more may be obtained; after which the ground will be in excellent order to lay down with grass seeds."

Notwithstanding that lime is so very good a manure, Mr. Lummis prefers marle, if it can be had within the ground, or near the place where it is to be used; for though it be more chargeable at first, yet, lasting five times as long, it is in the end much cheaper. He generally lays near two hundred loads of it upon an acre, at about seven or eight bushels to the load.

Mr. Evelyn advises mixing the lime with the turf or sward, laying them alternately, turf on lime, and lime on turf, in heaps for six months; by which means it will become so rich and mellow, as to dissolve and run like ashes, and carry a much more cherishing vigour, than if used alone in a greater quantity, and without danger of burning out and exhausting the vegetative virtue which it should preserve. It is likewise greatly bettered by being mixed with dung, or with mud drawn from the bottom of ponds or rivers. In Westmoreland, they reap fine crops of barley from their sandy lands, by manuring them with lime and cow-dung mixed together.

The nature of lime on land is like that of chalk: it works downwards, as the farmers express it, and is therefore best treated in the same manner, laying it upon a lay the year before it is to be ploughed up. When used on land which lies upon a descent, it should by all means be mixed with dung, and laid principally on the higher part of the land; the consequence of which will be, that the rain will wash out the virtues of the lime and dung together, and carry them to the lower parts as it runs down. In fact, it does better on any land, when mixed with dung, than either of them alone. This is particularly observed in Shropshire, where they lay dung and lime together, about twenty loads of the former, and only twenty bushels of the latter, on an acre of ground. In Leicestershire, they sow or scatter the lime on wheat land when they sow the wheat; but on barley-land, the last earth but one, left it should burn the barley if sowed with it in spring. They allow five quarters to an acre of each, reckoning by the measure in which it comes from the kiln; for after it is flaked, those five quarters will make near ten.

Lime is thought to make corn grow with a thin husk. It is a great destroyer of moss and rushes, even after it has been flaked; as quicklime is of the remnants of furzes, after the old bushes have been grubbed up. Its hot quality renders it apt to over-burn dry soils. It certainly is most efficacious when spread directly from the kiln.

Mr. Marshall, in his *Rural Economy of Norfolk*, says, "1781, in May last I made an experiment with lime for turneps, by spreading a chaldron of lime (at the rate of three chaldrons an acre) across each of two pieces of turnep fallow, and marked the stripes with flumps.

"No apparent benefit arose from the lime until the late heavy rains fell; since which the plants have flourished, and the good effect of the lime is become evident.

"In March last I also made a similar experiment with lime for barley; but the crop did not, in any stage, receive apparent benefit from it. The summer, until after the barley had finished its growth, was dry.

"In the experiment with lime for wheat (see Min. 18.) the crop received no apparent benefit from the lime until the soil had been moistened with summer rains.

"From these and other observations I am of opinion, that lime does not act as a manure until it has been thoroughly flaked in the soil; and, from the last mentioned incident, it seems as if the rains of summer were necessary to promote its operation."

Mr. Lisle, whose account of lime is almost unintelligibly perplexed and confused, thinks it is best, especially on lands that work mellow, to spread and plough in this manure as soon as it is flaked, rather than to let it lie long in heaps covered with earth. He very properly gives it as a rule to all husbandmen, to be cautious of liming ground, and then ploughing out the heart of it; the bad consequences of which he himself experienced.

"I limed, says he, some years ago, in Wiltshire, seven acres for an experiment, and laid down one acre to its own natural grass. In two years time this grass was, and still is, worth forty shillings an acre. The third year, I laid down another acre, which is still worth thirty shillings a year.

year. The rest, which I ploughed five or six years longer, is not worth fifteen groats an acre. I have experienced the like in burn-baking ground."

The practice of Lower Normandy, where lime is chiefly used on lands newly broken up, is thus related by M. Duhamel:

"After giving these lands a shallow ploughing, they carry on the lime as it comes from the kiln, and lay about an hundred weight of it in a heap on every square perch; so that the heaps lie at a perch distant from one another; they then raise the earth all round the heaps, like so many basons: the earth which forms the sides of these basons should be a foot thick: and, lastly, they arch the heaps over with earth, six inches thick. The lime flakes under this covering, and is reduced to powder; but at the same time it increases in bulk, and thereby cracks the earth. If these cracks be not carefully stopped, rain will get through them, and reduce the lime into a paste, or kind of mortar, which will not mix with the earth, or answer the end proposed. Farmers are therefore very careful to examine the heaps from time to time, and stop the cracks. Some only press down the top of the heap with the back of a shovel: but this method is liable to a considerable inconvenience; for if the lime be in a paste within the heap, it is by this means beat together in such manner, that it becomes still more difficult to mix it with the earth: for which reason it is better to stop the crevices, by throwing a little fresh earth over the heap.

When the lime is thoroughly flaked, and reduced to powder, the heaps are cut with a shovel, and the lime is mixed as well as possible with the earth that covered it. This mixture is then thrown up in heaps again, and left exposed to the air for six weeks or two months: for then the rain will not hurt it.

About the beginning of June, this compost of lime and earth is spread upon land: but not by throwing it about unequally, or at random: on the contrary, it is taken up by shovels, and distributed in little heaps, at equal distances, on each perch of ground, it having been observed, that these little heaps promote vegetation, more than if the manure was spread uniformly all over the field; nor is it at all needed, if small intervals remain unlimed between each shovelful. The field is afterwards ploughed, for the last time, very deep: then, towards the end of June, it is sown with buck-wheat, which is covered with a harrow; and if any clods remain, they are broken with a hoe.

Buck-wheat occupies the land a hundred days; so that this grain, sown about the end of June, is gathered about the end of September. When the stalks and roots of this plant are dead and dried, the ground is ploughed up, and immediately sowed with wheat, which is harrowed in. After the wheat has been reaped, the land is ploughed as soon as possible. It is ploughed for the last time, in February or March, in order to sow oats; or in April for barley: but in this case it is turned up two or three times, to make it fine. All these different grains are harrowed in. A roller is passed over the oats when they are come up; and if any clods remain in the barley, they are broken with a hoe.

In the next February or March the land is ploughed again, in order to sow it with grey peas or vetches: and after these pulses have been reaped, one or two ploughings are given, to prepare it for wheat in the ensuing autumn.

The next year oats are sowed, sometimes mixed with a little clover; and then the ground is laid down to pasture for three or four years.

Sometimes no buck-wheat is sowed on land newly broken; but it lies fallow, from the month of March, with it was first ploughed, till October, when it is sowed with wheat, after receiving several ploughings during the intermediate time. These lands being, by this means, brought to a tolerable tilth, not above three quarters of the quantity of lime above mentioned is used on them, and they generally bear a better crop than those which are first sowed with buck-wheat.

Some farmers think a perch too great a distance for conveniently spreading the lime. They therefore make the heaps less, and increase their number in proportion. Others lay their lime in ridges, from one end of the field to the other; which facilitates the spreading of it. Being persuaded that lime is most efficacious when it lies shallow in the ground, they first plough it in, and then give a second ploughing before they sow, which brings it again near the surface."

Mr. Young, in his *Annals of Agriculture*, vol. XIV. in a

review of Mr. Marshall's *Rural Economy*, says, "Another economical practice in the management of lime, is equally entitled to notice. If a quantity of lime be fetched in autumn, or the early part of winter, to be used in the spring, when team labour is more valuable, it is thrown up into a regular roof-like heap or mound, and thatched as a flack, a small trench being cut round the skirts to catch, with an outlet to convey away rain water. By this admirable precaution the surface of the heap perhaps to a considerable depth, is prevented from being run to a mortar-like consistence by the snows and rains of winter, and thereby rendered in a manner useless."

Mr. Young, in his *Annals of Agriculture*, vol. IV. recommends the mixing of lime with dung for manure in the following manner:

"Cart the dung out of the farm-yard, some in December, and continue to do it as made, in the following months, till the heap amounts to about 120 loads, each 40 bushels; if made larger, the dung does not rot so well. When finished leave it about two months, and then add 200 bushels of lime, which is sold at the pit at 5d. per bushel; mix the whole together immediately. But it is to be observed, that the dung must not be dry; if it is, it will fire by being mixed with lime. Let it lie three months, and then stir it over again. The expence of the first stirring is 1d. a load, and of the second 1d. Carry it on to the pea stubble as soon as harvest is over, and plough it in for barley; if the season does not suit for carting, take the opportunity of a frost. This management has answered so well, that upon an average of 12 years, my barley crops have amounted to 4 qrs. 6 bushels per acre. I have at different times laid some dung on without lime being mixed, and the difference was very perceptible; so that from many experiments I find it necessary to spread 12 loads an acre instead of 10, which, with the lime, is the usual quantity.

"The benefit resulting from the lime is to be attributed to two circumstances. First, it destroys the seeds of weeds, so that I have always found the land cleanest where the lime mixture is laid; and second, it brings the dung forwarder, by raising the fermentation higher."

Lime is commonly said to enrich land greatly at first; but afterwards, when its efficacy is exhausted, to leave the ground more barren than it was before. Lime readily unites with every unctuous substance, and renders it more soluble in water. By this means, all such particles mixed with the soil may be more speedily converted to the nourishment of vegetables, than they might otherwise be. Indeed, if the farmer's avarice, or want of judgment, tempt him to over-crop the ground, it may be left without matter fit to nourish plants, till a fresh supply is brought; but if it be judiciously cropped, and left in good heart under grass, or any other produce which does not impoverish the soil, the effect of the lime will be more durable, and more advantageous than is generally imagined.

Mr. Marshall, in his *Rural Economy of Yorkshire*, says, "Lime is a sheet-anchor in the Vale husbandry. It is used invariably, I believe, on every species of soil, and in most cases with great success. It seems to be at present a received idea that the business of aration could not be carried on, or at least that the present rents of land could not be paid, without the assistance of lime.

"It is not my intention to attempt to prove or disprove the truth of this opinion. Suffice it for me to say, in this place, that I am not acquainted with any country in which lime is held in such high repute, nor where the manufacturing of it is so common a practice among farmers, as it is in this. Almost every principal farmer upon the margin burns his own lime.

"There are, besides, great number of sale kilns for smaller farmers, and for the centre of the Vale, where no materials for burning are to be had. There is an instance of one man occupying eight or ten kilns; burning two or three thousand chaldrons yearly.

"But beneficial as lime undoubtedly is in some cases to corn, its benefit to grass is a matter in dispute, even among the farmers of Yorkshire. Incidents are authenticated in which, to general appearance, it has been detrimental.

"But without the assistance of comparison, the judgment is at a loss to ascertain with any degree of precision the effects of manures. Nevertheless, general appearances to those who have a knowledge of the nature of the soil, have their weight.

"It seems, however, to be a generally received idea, that lime which is laid on for grafs is not thrown away; for whenever the land is again turned up, its benefit to corn will have full effect.

"Long as lime has been in common use as a manure, the proper method of applying it to the soil is far from being universally practised.

"The methods of liming are various.

"The worst is that of laying it in large heaps, and suffering it to run to a jelly before it be spread upon the land.

"Next to this is setting it about the land in small hillocks; for although these hillocks be spread before they approach to a state of mortar, this method is injudicious.

"Lime which falls in the open air does not fall to powder, but breaks into checquers, or small cubical masses; which being once buried in the soil, may remain in it for ages without being mixt intimately with it.

"As far as experience and theory have yet reached, lime ought to be spread in a state of perfect powder, thereby lodging it in the pores of the soil; and thus, by assimilating the two ingredients, form with them one homogeneous calcareous mass.

"A single stone exposed to a moist atmosphere falls entirely into granules, not into powder. It is observable, however, that much depends upon the nature of the stone from which the lime has been burnt. Stones of a uniform texture, as most marbles, are less liable to fall in granules than stones which are naturally composed of grains, or are divided by fissures into natural fragments.

"The smaller the heaps, the nearer they approach to single stones; there is a greater proportion of surface, and consequently a greater proportion of granules.

"It is therefore the practice of judicious husbandmen to set lime upon the land in load-heaps, and spread it over the soil out of carts, as soon as it is sufficiently fallen.

"There is an instance of practice in this neighbourhood, and, I believe, only one, which is still superior to that last-mentioned. In this instance, the load-heaps are turned over, not so much to finish the falling, as to gain an opportunity of burying the granulous surface of the heap; by which means the fragments are at least lessened, if not reduced to powder.

"In the Morelands a still better practice is said to prevail. There the heaps are interlayed and covered up with moist turf-mould, (the rubbish from peat and turf fuel), which bringing on a rapid fall, the whole is set on fire, and the surface kept free from granules by a covering of dry ashes.

"This leads to a general improvement in the method of slaking lime; cover up the heaps, whether large or small, with soil either of the field they are set in, or that of lanes or ditches carted to them for the purpose; and if a speedy fall be required, throw water over this covering.

"If lime be used on fallow for wheat, it is generally spread on in July; good farmers making a point of harrowing it in as fast as it is spread, and plowing it under with a shallow furrow, as soon as convenient.

"The usual quantity set on is three to four chaldrons an acre." In his Minutes of Agriculture, in the Midland Counties, Mr. Marshall says that "The lime produced from Breedon Hill is of a singular quality.

"Five or six quarters an acre are found to be a beneficial dressing for the lands of this neighbourhood. But it is an opinion, universally admitted, that if much more than that quantity be laid on, it is poison to the land: it having been observed, that where, by accident, a greater quantity has been scattered, no grafs will grow: and that where load-heaps have stood, no corn will thrive; but, instead of it a bed of couch and thistles appears: a circumstance which has set many men against it, under an idea that it breeds these two pests of cultivated land."

LIME-KILN. See the article **KILN**, and **BURNING LIME**.

LIME-STONE, a species of stone which will burn into lime. See the article **LIME**.

LIME-TREE, or *Linden-Tree*, a beautiful tree for walks, and other decorations, in parks &c. and of which Mr. Miller has enumerated four species.

All the species of the lime-tree are easily propagated by layers, which will, in one year, take good root, and may then be taken off, and planted in a nursery, at four feet

distant row from row, and two feet asunder in the rows. The best time to lay them down, and to remove them, is, when their leaves begin to fall, that they may take root before the frost comes on, though they may be transplanted any time from September to March, in open weather; but if the soil be dry, it is much the better way to remove them in autumn, because it will save a great expence in watering, especially if the spring should prove dry. In this nursery they may remain four or five years, during which time the ground should be dug every spring, and constantly kept clear from weeds, and the large side shoots pruned off, to cause them to advance in height; but the small twigs must not be pruned off from the stems, because these are absolutely necessary to detain the sap, for the augmentation of their trunks, which are apt to shoot up too slender, when they are entirely divested of all their lateral twigs. If the soil in which they are planted be a fat loam, they will make a prodigious progress in their growth, so that in three years time they will be fit to transplant out, where they are to remain.

They may also be propagated by cuttings; but as this method is not so certain as by layers, the other is generally practised. In order to obtain proper shoots for laying down, a lime-tree is cut down close to the ground, from the roots of which a great number of strong shoots are produced the following year; these will be large enough to lay down the succeeding autumn, especially if the smallest of them are cut off close early in the spring; for when too many shoots are suffered to grow during the summer, they will be much weaker, than if only a sufficient quantity be left. For the manner of laying down these shoots, see the article **LAYER**.

The timber of the lime-tree is used by carvers, it being a soft light wood; as also by architects for framing the models of their buildings; the turners likewise use it for making light bowls, dishes &c. but it is too soft for any strong purposes. *Miller's Gard. Dict.*

LINDEN-TREE. See the preceding article.

LING, heath.

LINSEED. See **FLAX-SEED**.

LIPPITUDE, in a horse, is a defluxion of a salt, sharp humour from the eyes, attended with a violent itching, pains, and redness; the eye-lid swelling, so as to turn the inside as it were outward; the sight grows dull, and the eyes frequently closed up: it usually attacks young horses at about five or six years of age; it comes and goes once in three months, or oftener, and continues each time, more or less, from a week to a month; thus it goes on, perhaps, two years or more, when all the symptoms cease, but end in a cataract.

The sharp humour abovementioned runs down the cheek in greater or less quantities, and is so hot as to scald and destroy the hair there: the veins in all the parts about the eyes are very turgid, sometimes the eye appears dull, at others cloudy, then again clearer: but it is rarely sprightly: the humour that distils from the eyes is sometimes so thick as to close up the eye-lids for some time.

The seat of this disease is in the glands on the inside of the eye-lids; and it may be observed, that if they are of a good size, and well shaped, if they are clear, and the sight is good, as soon as the sharp humours abate, if the returns are less violent and more rare, some hope of recovery, without ending in a cataract, may be indulged; but if the eye shrinks and grows less, a cataract will certainly ensue.

In order to the cure, if the eye is not in a perishing state, and the horse in low condition, bleed; then, once in eight days give a cooling purge; and, on the days free from purging, give diuretics, particularly nitre, to the quantity of two ounces in a day: and, in order to strengthen the relaxed glands and membrane of the eye-lid, many light scarifications may be made, with a lancet, on the inside of the eye-lid, which turns out; then the whole eye may be washed two or three times a day with the following lotion:

Take of white vitriol, two drachms; camphire, one drachm; rub them well together, then gradually mix them with a pint of water.

When by these means the sharp humour decreases, give the following alterative powder, every morning, for two or three months; then, after an interval of the same time, repeat it as before:

Alterative

Alterative Powder.

Take of crude antimony, half an ounce; gum guaiacum, two drams; mix them for one dose.

When the blood vessels about the eyes and parts adjacent are extremely turgid, they may be well bathed, two or three times a day, with strong vinegar. It is the practice of some, on these occasions, to take up the principal branches of veins; and in some other cases, to tie up arteries; but this method is rather hurtful than otherwise, by checking the circulation and depriving the parts of nourishment.

If the eye seems to shrink, wash it with the following, two or three times a day:

The Collyrium.

Take of crude sal armoniac, two drams; brandy, four ounces; lime-water, one pint, mixt.

With this collyrium, try also what a better diet will do; allow him a moderate quantity of oats: good nourishment and moderate exercise may give a favourable turn; indeed, in disorders of the eyes, hard labour should be universally avoided. It is worthy of remark, that low keeping, after good and plentiful feeding, greatly hurts the sight; and hard labour, added to the sparing diet, aggravates the disadvantage considerably. Colts are often made to go blind, by full feeding, and early hard working.

These means not succeeding, the last resource is mercurials; and, perhaps, the most proper will be the turbith mineral, which may be given as directed for the farcy.

LIPS in a horse. If these be thin and little, they contribute to a good mouth, but the contrary if they be large and thick.

LIQUORICE, a plant propagated for medicinal uses. It grows to about four or five feet high; its stalks are hard and woody; its leaves small and roundish, standing together on the two sides of a rib, and making what botanists call a winged leaf.

A correspondent of the editors of the *Museum Rusticum* has given the following directions for cultivating this plant, founded on a long series of experience:

"The common culture of liquorice is not difficult to be learned; and this with proper attention, will enable any thinking farmer, that knows his business, to cultivate it to advantage.

"This plant thrives best on a deep, loose, rich mould; and if it is fresh land, that has not for many years borne corn, the profit will be the greater, as the crop will be larger, and the roots of a finer quality.

"A rich sandy soil, provided it is deep, will do well for this plant; and it must always be remembered, that too much moisture is its greatest enemy; let no one therefore attempt to plant it on a damp clay, lest the whole crop be cankered.

"Land cannot be made too fine, nor dug too deep, for liquorice; it should be, at least, moved with the spade to the depth of two feet and a half, and if a little deeper, so much the better.

"If the land, on which the liquorice sets are to be planted is fresh, rich, and in good heart, it needs no manure for the first crop; but if it has been for some years in tillage, the planter will do well to give it, in the summer time, a good dressing of very rotten dung, lime, and coal-ashes or soot, mixed together, some months before, in a compost; the quantity must be regulated by the state of the land, always remembering that this plant requires a great deal of nourishment, and is a great impoverisher of land, though it extracts much of its nourishment, or food, from a considerable depth, at a distance from the surface; some of the roots running five or six feet, at least, into the ground.

"When the ground is properly prepared, reduced to a very fine tilth, and laid level, some liquorice runners, or sets, are to be procured. These must be cut into pieces, about eight or nine inches long each, and planted in rows, with dibbers armed with iron points. I make my rows two feet asunder, put my sets fifteen inches from each other, and when three rows are planted on a six-foot bed, I allow two feet more of interval betwixt bed and bed.

"When I put in my sets with the dibber, I leave the upper end of each set just level with the surface of the ground; I should have observed, that I have all my sets care-

fully inspected before they are carried into the field, to see that each of them has one, if not two eyes, or buds, without which they would make no shoots.

"When the whole spot of ground is planted, I make my labourers dig up the intervals one spit deep, and spread the earth on the beds; this raises them about two inches above the head of the sets, and by lowering the intervals, serves in wet seasons to drain the beds. I generally contrive to get this work done by the last week in September; but in favourable years, the middle of October is not too late.

"If the weather proves mild, I have no farther trouble with them during the winter; but if it is likely to freeze hard, I cover the beds with pease-haulm, or long dung, or some such matter, to forward the growth of the roots in the spring, and protect them during the winter, from the frosts.

"Early in the spring, on the first appearance of the weeds, I allow my liquorice a thorough hoeing; and this is several times repeated in the dry weather of the summer.

"The winter following, I again cover them with long dung, and in the spring, before the roots begin to shoot, I have the spaces betwixt the rows on the beds loosened with a spade, and the intervals are well dug; immediately after which, I give the land a slight dressing of coal-soot, sown by hand: it should be thick enough to make the land look black: this the first rains wash in, and it greatly warms and invigorates the plants.

"The second and third summers, all I have to do, is to keep my crop clear of weeds: this indeed, is very necessary, and the hoeings for this purpose must be more or less frequent, according to the season; generally, three times in the summer are quite sufficient, especially if the land was well prepared before the sets were planted.

Many good sensible farmers, whom I have known to cultivate this plant in autumn, have a practice of cutting down the stalks, whilst they are in full sap, thinking thereby to strengthen the roots. I differ from them, however, in opinion, and am rather apt to imagine that this cutting of the stalks, whilst the sap is in motion, must be prejudicial to the roots. It is, therefore, my custom, always to defer cutting off the stalks, till they are withered, and begin to decay; nature then indicating, that an abstraction will be of service.

"These roots should have three summers growth before they are fit to take up: it is very seldom that they have attained a proper size at two years end; and if you leave them longer than three years in the ground, the roots are apt to grow sticky, and lose a part of their saccharine quality.

"I never take them up till the sap is entirely at rest, and the leaves and stalks are withered: they are then in prime order, and fittest for sale.

"If these roots are taken up while the sap is in motion, either early in the autumn, or late in the spring, they are apt to shrivel, and lose much of their weight, and are, besides, more disposed to ferment and perish.

"The best way of taking them up is, to dig the ground over as deep as the principal roots run, having pickers ready to gather up the roots as fast as they are thrown up by the spade.

"My general practice is to get rid of my roots as soon as I conveniently can: and I find it better so to do, than to wait for the rising of the markets. I have had, from one acre of fine, fresh, rich land, above 3000 pounds of saleable root, which has produced me above sixty pounds; but this was many years ago, my crops not being generally now so large.

"When I have taken up a crop of this root, if it was planted on fresh land, I generally prepare the same ground to yield me another crop; and this takes me near a year.

"I, in the first place, give it, during the winter frosts, a thorough good dressing of well-rotted dung, mixed with lime; of this I lay on large quantities, still having regard to the condition of the soil, and ploughing it well in the ensuing summer.

"In such loose soils, as are proper for this plant, there is no occasion to dig the land for this crop, the taking up the roots having stirred it to a great depth: this, with three or four summers ploughings, is sufficient.

"As to the rest, I manage the same as I did for the preceding crop.

"If the land, which has borne me a crop of liquorice-

root, was not fresh land when it was planted, but has been any time in tillage, I scarcely ever chuse to plant it again with the same crop, without allowing several years of interval, at least seven; but in this case, I frequently sow oats in the spring, to abate the rankness of the soil; and it will then, with a very slight dressing, give me a good crop of wheat.

"In my method of cultivating this plant, I always allow space enough for the roots to extend in search of food; and this is my reason for planting my rows at two feet distance; I am, besides, very careful of keeping them clear of weeds, and that, particularly, during the first summer; being very sensible that, without this precaution, they would be in great danger of being choked up, and robbed of their proper share of nourishment; particularly, they would receive no benefit from the dews, which are so friendly to vegetation; and even the sun's warmth would be, in a great measure, kept from the roots by the shade of the weeds.

"Many, who plant liquorice, allow much less space than I do betwixt the rows, and will yet, the first summer, take off a crop of onions, or spinage, or young carrots, and think it so much clear profit; but the question is, whether these crops may not, during the time they are on the ground, be, to all intents and purposes, deemed weeds, having nearly, if not altogether, as bad effects as weeds would, if permitted to grow with the crop.

"Some, worse farmers, continue this practice two years of its growth; but it is quite needless to condemn this method of culture, as it cannot but stand self-condemned.

"In the dressings I give my land, for preparing it to receive this plant, experience has convinced me that lime is a much sweeter manure than stable-dung: in fact, this last is not, on any account, to be used till it is quite rotten, and then lime is very properly added to it as a corrector.

"Some friends of mine, who live very near London, have attempted to cultivate this plant on their lands; but they find it does not answer; and this, on account of the great richness of the soil, owing to the great quantity of London dung laid on it. It is true, the roots were at three years end larger than mine; but they were not so bright, had a blacker coat, and were deemed greatly inferior in quality.

"Should any of your readers be inclined to cultivate this plant, by following these directions, not implicitly, but according to their discretion, the circumstances of their soil, &c. considered, they cannot well fail succeeding." *Museum Rusticum, vol. I. p. 252.*

Liquorice loses greatly in weight, if kept in a dry place. In order to discover how much it wasted, I made choice of a piece of a single root 13 inches long, and full $\frac{1}{2}$ inch diameter throughout, which weighed five ounces; and nine small roots, 13 inches long each, and from $\frac{1}{4}$ to $\frac{3}{8}$ of an inch in diameter; they weighed also five ounces. All these were put into a drawer in a dry room, the beginning of February, and were weighed the beginning of August following, and then the largest single root weighed two ounces and three quarters, and the nine small roots also weighed full 2 $\frac{3}{4}$ ounces; so that in six months these roots lost almost half their weight. They were green and juicy when put into the drawer, and were now pretty dry and hard, but not quite so dry and hard as some of the same liquorice that had lain all that time in the open room.

But liquorice may be kept in moist sand, or laid in the earth as long, with very little waste or loss of weight.

As liquorice is an upright growing plant, and not apt to lodge, and its roots descending deep, it is very proper for the horse-hoeing culture, in which it will arrive to greater perfection than in the usual method of cultivating it, as described above.

In Yorkshire, where liquorice is cultivated in a rich sandy soil, its roots penetrate to the depth of three or four feet, sometimes more; and the digging the ground all over to that depth, when the liquorice is taken up, is very expensive. As a saving in this article, the planters in digging up the ground, lay it in a proper form and replant it, making one digging serve for both purposes, which is a very good way; but they set the plants much too close; whereas if they planted it in rows, at about four feet distance, or more, and horse-hoed it, the weeds might be destroyed, and the land greatly improved, especially if trench-hoed; and the produce would be very great, after

so fine a preparation of the land by digging. Add to this, that the method of cultivation by the hoe-plough is much cheaper than by hand-work.

LITTER, the straw laid under horses, &c. Straw at 15s. per load, is a more eligible litter, and cheaper than fern at 5s.

LIVE HEDGES. See FENCES.

LIZENED Corn, lessened, shrunk, or lank corn.

LOBBY. Mr. Marshall, in his Minutes of Agriculture, in the Midland Counties, says, that "Every farmery ought to have a lobby, and a croft, appending to it; serving as a double fence: thereby preventing stock from running over, poaching and injuring the farm: the latter for calves, a saddle horse, and invalids.

I found the conveniency of a lobby in Surry; and the want of one in Norfolk, and in this place; where I can foresee the use of that which I am now forming, with a skreen of planting;—embosoming the entire farmery, in such a manner as to shelter it, effectually, from the north and east winds."

LOAM, an earth composed of dissimilar particles, hard, stiff, dense, and rough to the touch, and composed of sand and a tough viscid clay.

LOE, a little round hill, or heap of stones.

LOG, a large, shapeless piece of wood.

LOOP, a hinge of a door.

LOP, a flea.

LOPPED Milk, such as stands till it fours and curdles itself.

LOPPING, the cutting off the side branches of trees.

It is very observable that most old trees are hollow within; which does not proceed from the nature of the trees, but is the fault of those who have the management of them, who suffer the tops to grow large before they lop them; as the ash, elm, hornbeam, &c. and persuade themselves, that they may have the more great wood; but in the mean time, do not consider that the cutting off great tops endangers the life of a tree; or, at best, wounds it so, that many trees yearly decay more in their bodies than the yearly tops come to; and at the same time that they furnish themselves with more great wood, they do it at the loss of the owner. And indeed, though the hornbeam and elm will bear great tops, when the body is little more than a shell; yet the ash, if it comes to take wet at the head, very rarely bears more top after the body of the tree decays. Therefore, if once these trees decay much in the middle, they will be worth little but the fire; so that if you find a timber-tree decay, it should be cut down in time, that the timber be not lost.

The lopping of young trees, that is, at ten or twelve years old at most, will preserve them much longer, and will occasion the shoots to grow more into wood in one year, than they do in old tops at two or three. Great boughs, ill taken off, spoil many a tree; for which reason they should always be taken off close and smooth, and not parallel to the horizon; and cover the wound with loam and horse-dung mixed, to prevent the wet from entering into the body of the tree.

When trees are at full growth, there are several signs of their decay; as the withering or dying of many of their top branches: or if the wet enters at any knot; or they are anywise hollow or discoloured: if they make but poor shoots; or if woodpeckers make any holes in them.

This lopping of trees is only to be understood for pollard-trees; because nothing is more injurious to the growth of timber-trees, than that of lopping or cutting off great branches from them. Whoever will be at the trouble of trying the experiment upon two trees of equal age and size, growing near each other, to lop or cut off the side branches from one of them, and suffer all the branches to grow upon the other, will in a few years find the latter to exceed the other in growth every way; and they will not decay near so soon.

All sorts of resinous trees, or such as abound with a milky juice, should be lopped very sparingly; for they are subject to decay when often cut. The best season for lopping these trees is soon after Bartholomew-tide; at which time they seldom bleed much, and the wound is commonly healed over before the cold weather comes on. *Miller's Gard. Diet.*

The generality of the world are against pruning timber trees at all, and where they naturally grow straight and regular, it is much better let alone. But all common faults in shape may be regulated by thus lopping them while young, and

and it can be attended with no ill consequence to the timber; for the cut not lying near the timber-pith, cannot affect it, when grown up, and squared in the working for beams and other uses, or to be quartered; for all the defects occasioned by such wounds, are in the superficial parts, and all the four quarters are perfectly sound within.

As to the largest forest trees, they should not be lopped at all, except in cases of great necessity, and then the large boughs must not be cut, but only the side branches; and even these must be cut off close, that the bark may soon cover the wound, and yet a little slanting, that the water may run off, and not lodge upon the cut part.

If there is a necessity of cutting off a large bough, as by its being broken or cankered, let it be cut off slanting at about four feet distance from the body of the tree, and that if possible near some place where there is a young shoot from it, which may receive the sap, and grow up in its place. No stump must be left standing out farther than this, because they are wounded parts which never can heal, and which will always be letting in the water, and will serve as pipes to convey that water into the heart of the body of the tree, and by degrees will utterly spoil it. All that grow upright, whether they be large or small branches, must in cutting be taken off slanting, never evenly, for the same reason; those boughs that bear from the head are to be cut with the slope on the lower side, and on any occasion that great wounds are given to a tree, they should be covered with a mixture of clay and horse-dung, which will make them heal much sooner than they otherwise would do. *Mortimer's Husbandry, vol. II. p. 91.*

To LOWK, to weed corn.

LUCERN, a plant frequently cultivated in the manner of clover, and known among botanists by the names of *medica* and *medicago*.

It is the *alfafa* of the Spaniards, and the lucern grand treffle, or *fœnum Burgundiacum*, as some botanists call it, of the French. It has a perennial root, and an annual stalk, which rises full three feet high in good land, and is garnished at each point with trifoliate leaves, whose lobes are spear-shaped, about an inch and a half long, and half an inch broad, sawed towards the stalks. The flowers grow in spikes, which are from two or near three inches in length, standing upon naked footstalks two inches long, rising from the wings of the stalks: they are of the pea-bloom, or butterfly kind; of a fine purple colour, and are succeeded by compressed moon-shaped pods, which contain several kidney-shaped seeds. It flowers in June, and its seed ripens in September.

There are the following varieties of this species of lucern, viz. one with violet-coloured flowers; another with yellow flowers; a third with yellow and violet flowers mixed; and a fourth with variegated flowers: but as Mr. Miller observes, these are only variations of the same plant, arising accidentally from the seed. However, neither the yellow nor the variegated flowered lucern is ever so strong as that with purple flowers; nor is it consequently so profitable to the husbandman.

Columella calls this the choicest of all fodder, because it will last ten years, and will bear being cut down four and sometimes six times a year; it enriches the land on which it grows, fattens the cattle fed with it, and is a remedy for sick cattle. About three quarters of an acre of it is abundantly sufficient to feed these horses during the whole year. Yet, notwithstanding it was so much esteemed by the ancients, and hath been cultivated to great advantage in France and Switzerland for many years, it has not yet found so good a reception in England as it justly deserves; nor is it cultivated here in any considerable quantity, though it will succeed as well in this country as in either of the last mentioned: being extremely hardy, and resisting the severest cold of our climate.

Mr. Rocque lays it down as a maxim in his practice, that lucern will grow on any soil, provided it be not so wet as to rot the roots.

The strongest land is however to be preferred, and the deeper the soil the better will be the crop, as the roots will have room to extend themselves.

The land should be prepared in the same manner as for barley, being ploughed, harrowed, and cleaned from all sorts of weeds; and the stronger the land is, of course the more ploughing and harrowing it take will to mellow it, and bring it to a fine tilth.

When this work is done, the lucern seed must be sown

broad-cast, (not in drills) in fine weather, after the rate of about fourteen pounds to an acre.

This allowance of seed will be sufficient to supply the number of plants that will be wanted to yield a full crop; but they will not stand so thick as to starve one another, though there is some allowance for part of the seed failing.

But should every seed take, the method of culture hereafter recommended will sufficiently reduce the number of the plants, and, without the trouble and expence of the New Husbandry, give each plant space enough to extend its roots, and collect the necessary quantity of nourishment.

To return to the culture, before the last ploughing, the land should be manured, not with old rotten stuff as is usual, but with fresh stable-dung, that has been thrown up in a heap three or four weeks to heat and ferment. This will enable the young plant to push forth its leaves and stalks with luxuriance, and get forward in its growth the first summer.

When the dung is in full fermentation, it is to be laid on the land and ploughed in as soon as possible, that the salts of the dung may not have time to evaporate: the land must then be harrowed and sown, and afterwards harrowed again with a light or bush harrow; and lastly, rolled to settle the ground and break the clods.

If corn is to be sown amongst it, it should be only half a crop; otherwise it will be apt to destroy the lucern, especially if it proves a wet season, and the corn is rank: but if no corn is sown amongst it, the lucern will thrive much better.

Lucern may be sown from the beginning of March to the end of May; but April, in dry weather, is the best time.

If much rain falls on the new-sown lucern, it will be apt to swell too fast, and burst; but if it holds fine for three or four days, it will be in no danger.

Mr. Rocque does not approve of drilling the lucern, because the roots are too much confined in the drills: they say it is to clean the lucern between the rows that they drill it: but it is for want of knowing the nature of lucern, and it discourages people from sowing it, drilling and hoeing being very expensive ways; the quickest and cheapest, and by much the best way, being to sow it broad-cast, like clover, as the roots will stand nearly at equal distances one from another every way.

Lucern requires, it is true, a great deal of nourishment from the earth; but there is no occasion this nourishment should be supplied by the surface. It is well known that the roots of lucern will run to a great depth in the ground, from whence they must of course extract a large quantity of food: this spares the surface; and in fact the land where lucern grows requires only that the natural grass should be prevented from getting to a head, which it is in our climate very apt to do, and if let alone would soon choke up the lucern.

It is mentioned above, that if corn is sown with lucern, it should be only half a crop: some of your readers may not, perhaps, readily comprehend the meaning of this expression: therefore, to render it more clear, I shall here observe, that when barley or oats are to grow with lucern, a bushel only of either, according to Mr. Rocque's method, is to be sown first on an acre, then fourteen pounds of the lucern.

One thing is to be observed, that if the corn, notwithstanding its being sown so thin, should grow so rank as to endanger the lucern, it will be much best to mow it before the harvest, as it is better to lose the crop of corn than to kill the lucern.

The barley, or oats, however, need not be entirely lost, as they may, when mown, be given green to cattle; or, if the weather is fine, will make excellent hay, provided they are properly dried; and it is best to do it in the swarth, as the rich juices are in that manner less exhausted. To sow it later than May is dangerous, for fear of a dry season, or its being eat up by the fly.

Lucern will not grow on fresh-broke-up land; it must be tilled a year or two: pease and beans, for one year, will prepare the ground; but, above all, potatoes excel for sweetening and mellowing of land: the next season a fallow for turnips, and when the turnips are fed off with sheep, it will greatly enrich the land, which should then be prepared for lucern.

In regard to the tillage, and time of sowing the lucern-seed, the nature of the soil must be considered. Heavy, strong,

strong land will require more ploughings and harrowings; and to be later sown: light land will need fewer harrowings and ploughings; and to be sown earlier, that the young plants may have strength to send their roots deep into the ground, before the hot dry weather comes on to hurt them; and if, for the first time, the land had a trench-ploughing, it would be of great advantage.

In Languedoc they sow no corn with the lucern; and when it is six or seven inches high, they mow it; by which all the seeds of annual weeds are cut off and killed.

In Normandy, the climate being much the same as in England, they sow corn with it.

In Picardy, and about Paris, they sow it, some with, others without corn.

At Avignon, when their lucern begins to decline, they manure the ground and plough afresh, and sow it with corn and lucern; and the old roots, growing again with the seed, make another fine crop: the ploughing will not hurt the old roots.

If a full crop of barley is sown with lucern, and the barley grows very strong, the best way is to mow the barley when it is in the ear.

If forward pease are sown on new-broke-up land to prepare it for lucern, it may be done in one year, and turnips sown on it as soon as the pease are off: the turnips may be fit to seed off by Christmas; and as soon as the turnips are off, the land should be ploughed, and lie fallow till a proper time to stir it again; or it may have a trench ploughing, as before directed.

This method of giving land a trench-ploughing, to prepare it for lucern, is much to be recommended, as it stirs the earth almost as deep as if it was dug with a garden spade: or what advantage this must be to a plant that sends its roots deep for nourishment, need not be mentioned, as it cannot but be obvious to every reader.

Was labour cheaper than it is in England, it would doubtless be much the best way to dig by hand all the land that was destined to lucern: many advantages would result from this method of tillage, and particularly the weeds and grass would not be so apt to grow as in ploughed land.

I would heartily recommend it to some of the gentlemen in Ireland, to sow with lucern some of their land that has borne a crop of potatoes; it could not fail succeeding, and they would have a fair opportunity of trying what crops this plant will, when best cultivated, yield.

I cannot but think, that on good land that has borne potatoes, there might be five good mowings in a year, particularly in Ireland, where the climate is rather milder than in England; and this without injuring the roots. An easy experiment would, however, soon make this matter known: I therefore heartily recommend it to the attention of your Irish readers; they are every day improving their lands, and will, doubtless, not suffer this hint to pass unnoticed.

When we consider the many advantages resulting from the culture of this plant, it is astonishing that it should so long escape our regard: the hint was given us by the Roman writers on the subject of agriculture, but we were too much attached to old customs to improve it.

In hot summers the seed may be sowed in England, but not from the first growth; that being generally too rank, and subject to rot at bottom.

In Languedoc they save it from the third growth; but as this climate is colder, it will not have time to ripen, unless saved from the second growth.

A dry soil is best to save the seed upon, as it is not so apt to grow rank; and then it may possibly do from the first growth.

As lucern, if the land is good, will bear several crops in one year, like clover; what Mr. Rocque means by the first, second, and third growths, are, he says, the different crops it produces in one summer, which are three, four, and sometimes five mowings, in case no seed is saved from it: if seed is saved, it must be from the second growth: the seed will be ripe in September, and must be gathered by hand.

When the plants are one year old, it will be proper with a large harrow, to go over your land as often as is sufficient to root up annual weeds and grass.

The harrow will not hurt the lucern, the roots of it being very tough: this must be done in dry weather, be-

fore it begins to sprout, which is very early in the spring that the weeds and grass may die; and if there are any patches of ground where the seed miscarried, a little seed must be sown and the spot harrowed: a dressing with rotten dung, at the same time, will repay the expences of it by a larger crop; if the harrow should cut or wound any of the roots, they will sprout and grow notwithstanding.

The second spring, after sowing, it will be proper to plough the ground, where the lucern grows, with a drill-plough, with a round share, without a fin or feather, and without a coulter, to prevent the roots being too much hurt. It should lie rough a few days to dry and mellow; then in fine weather, be harrowed down to mow it the closer.

One, not used to the culture of this plant, will be apt to think, that ploughing will destroy the lucern; but any gentleman, that will take the trouble to call at Mr. Rocque's, may be convinced that experience teaches the contrary.

To make hay of lucern, it should be mowed as soon as the bloom appears, or rather sooner: it must not be spread, like common grass, but lie in the swarth, like clover, and turned in the same manner; or the leaves, which are most nutritive, will drop off.

If suffered to stand too long before it is mowed, the stalks will be too hard for the cattle to eat it, and it loses much of its goodness.

The hay is good for all sorts of cattle; and when horses are fed with it, they should not have their full allowance of corn; the lucern answering, in a great measure, the purpose of both corn and hay.

It is also the most profitable of any sort of fodder to feed horses with in the summer, by mowing and giving it to them green.

If the land is good the produce is incredible; and according to the goodness and depth of the soil, so will be the crops.

Mr. Rocque says he has seen lucern mowed five times in a season; yielding, at the five mowings, nearly eight loads of hay per acre.

The spring ploughing amongst the lucern must be annually repeated: it kills the grass and weeds, and makes the ground ferment, which promotes vegetation; and the oftener it is refreshed with a little dung on the surface, the better it will pay for the trouble of cultivating it. If the dung is laid on before the winter, that the salts may be washed in by the rain and snow, and ploughed in, in the spring, it will greatly add to the profit.

This is the substance of Mr. Rocque's account of the culture of lucern; but as different sorts of soil may require different methods of tillage, he has subjoined the idea of a harrow, with two handles like a plough, which may serve in light land instead of the plough, and will save some labour.

The teeth must be set at seven or eight inches apart in the first row, and about five inches long without the wood. The second row must be placed nine or ten inches behind the first, and so that the teeth of the second row may be against the spaces of the first row; and they must be an inch longer than those in the first row, so that the ground, being loosened a little by the first row, the teeth of the second row may go something deeper; and the teeth of the third and last row must be an inch longer than those of the second, and placed so as that they may go in the same track with the teeth of the first row.

The harrow must be made of one solid piece, four or five inches thick, and the lower side must be rounded off towards the hinder part where the teeth are longest; whereby the person that holds it by the handles, pressing down a little, may force the second and third rows of teeth deeper than the first: and by bearing up a little, he may prevent any but the first row from working. A very little practice will be sufficient to make any one use it as occasion requires, and it will be so steady that no unevenness of the ground will be able to throw it out of its work, as a clod or stone will a common harrow.

 The manner the teeth are to be placed in.

Let it be remarked, that the foremost row of teeth are placed in a line across near the middle of the block or plank;

plank; the other two rows behind that; and the fore part of the harrow should be heavier than the hind part when the weight of the harrow is suspended on the first row of teeth. The teeth should be pretty strong, and round; their being square, as usual, may hurt the roots a little, which is to be avoided as much as possible, though the consequence would not be very great.

Farmers are fond of sowing broad-cast, it being no easy matter to make them comprehend the utility of a drill-plough on any occasion: the sight of so complicated an instrument terrifies them; they think it moves by clock-work: and as to the labourers, it is a very difficult matter indeed to get them to hold it.

I am fully sensible, as I have already observed, of the good effects of sowing corn and pulse regularly with intervals, but cannot approve of this method when applied to artificial grasses; and it would be well if we were to improve our old practices, before we should even attempt to bring the new methods into general use. *Museum Rusticum*, vol. I. p. 78.

In the succeeding volume of the above work, another correspondent has made the following remarks on the above method delivered by Mr. Rocque:

This gentleman, says our author, owns he is against innovations in husbandry, because it is difficult to bring the farmer from the old methods; and therefore seems to conclude, new ones are not to be attempted; at least, that seems to be his reason, for being against what he calls innovations.

Under "restrictions, &c." he approves of the new culture, but thinks it "preposterous to extend it to artificial grasses;" adding, "the only benefit lucern can receive from the horse-hoe, is, that it keeps down the natural grass." This gentleman cannot be a practical cultivator of lucern; neither can he know the uses of the hoe-plough; if he did, he could not assert a fact so contradictory in itself.

To inaccurate observers the seedling plant of lucern may appear to have no lateral roots; but a careful examiner will find a great number of small ones, every one, or most of which are furnished with fresh nutriment by the operation of the hoe-plough.

We shall not contend about Mr. Rocque's superior profit: his situation gives him advantages superior to a distant residence; and therefore that should not be mentioned by a generous writer.

I am a favourer and practiser of the New Husbandry, and I do deny that it will be more expensive than Mr. Rocque's method, but, on the contrary, it will eventually be cheaper.

By this method, he may, for a few years, have pretty good crops; but at length his plants will be found to dwindle, and his crops will lessen, unless he annually adds seed to the ground; whereas, in the new culture, the crop will be continually improving; as to the quality being inferior, that will be the fault of the owner, if he lets it grow too rank. This argument of your writer makes against himself, as thereby he admits the superior luxuriances of the plants cultivated by the horse-hoe.

I have sown lucern in broad-cast more than once, and have seen others do it; and it ever failed.

Mr. Rocque's rule, as this gentleman says, is, "that lucern will grow on any land, if not wet:" this is certainly premature: it surely must have the occupation of a dry, rich soil, or I am sure, from practice, it will not succeed; and as to "the strongest being preferred," I believe every one, who tries the cultivation of it on such, and upon light ground, will find the latter best adapted to it.

But the notion of sowing corn with lucern is quite as "preposterous," I think, as the new culture for it; and how a man of Mr. Rocque's famed abilities should adopt such a method, I am at a loss to guess. Neither should lucern be sown in March, as in its infant state it is very tender and timid of frost.

This gentleman says, "it is for want of knowing the nature of lucern, that they drill it." I might retort upon him; but his mistaken zeal, I fear, will more injure the cause he means to promote, than I hope it will discourage the practice of drilling this valuable plant, as, by all men who adhere to rational principle, that hath been found the most successful method. See Tull, Duhamel, &c. I should be glad to know what "the surface of the ground is to be spared for:" is it to give life to the natural

grass, that common and destructive enemy of this excellent plant?

Our author mentions the cultivation of it in France, &c. If he was ever at Paris, with his present attention, he must have seen, that after a few years they always plough up the promiscuous sown lucern, in order to prepare the ground again for that, or some other crop, when the lucern begins to dwindle, by the weeds or natural grass robbing it of its nutriment.

How much more must that be the fate of promiscuous sown lucern in these kingdoms, where he admits grass is apt to get a-head? That is not the case in France, and yet even their promiscuous sown crops are short-lived.

I know not whether he be as conversant with potatoe-ground in Ireland as I am; but I cannot omit to inform you the tillage will not do for lucern; for this plant the ground ought to be well pulverized: whereas, in the general potatoe tillage of this kingdom, not more than about two feet in nine of the ground is cultivated.

The manner of harrowing the lucern, practised by Mr. Rocque, although the teeth be round, must wound many of the roots: that might be well, as it would thin them; but repeated harrowing will, in time, wound them all; and notwithstanding they will afford grass afterwards, yet, when the winter rain comes on, lodgments of water will be made in those wounds, which will bring on putrefaction, to the destruction of the plants, unless Mr. Rocque has the art of conducting the harrow-pins always in the same direction; and could that be the case, what would destroy the grass where they did not pass?

The manner of ploughing the lucern, practised by Mr. Rocque, is still approaching to the horse-hoe, though by no means so effectual. I wonder to see our author even favour that, since it may be deemed an "innovation." This ploughing is to be repeated every year, and harrowing also: to this dung is to be added, "as often as may be." I am willing to believe this gentleman knows nothing of the expence which attends these operations, *i. e.* ploughing, harrowing, and, above all, dunging, besides the value of the dung, which would always be acceptable for other grounds: whereas, in the drill way of sowing lucern, when the land is once put in good order, it may ever be kept so by the hoe-plough.

Lucern is a grass of such inestimable value, that it will answer almost any expence; yet if the most certain method to obtain success shall be found the cheapest, there can be no reason for pursuing one more precarious and more expensive, which will be found when Mr. Rocque's method, or at least that so warmly recommended by your correspondent, who asserts it to be Mr. Rocque's, is compared in practice with the one I venture to recommend to the practice of my countrymen, which I take upon me to say will command success, if pursued.

The land should be a flexible loam, dry, deep, and rich, either by nature, or made so by art; not but it will succeed to admiration should a quarry be under. It should be well pulverized by plough and harrow, laid as flat as possible, and cleared of all weeds, particularly scutch-grass: when the ground is in this form, let a small plough, with two mould-boards, be run up and down the field, at every three foot upon the flat surface: this will completely form three foot ridges. If a pair of drill-harrows be not at hand, let the crown of every ridge be carefully raked clean, and even with an iron rake, and one row of seed drilled very thin, about half an inch deep, along the middle of every ridge, the middle or latter end of April, (the beginning of May may do) and be carefully covered. This sowing of the seed may be done by hand, if a drill-plough be not ready. By a master's attendance, a great deal may be done in a day.

Thus it may remain till weeds begin to appear, when the hoe-plough, or a small common one, should take away every alternate side of the ridges, as near the lucern as can be with safety (I go within two or three inches of my drilled crops.) In three or four days, return the mould to the former places with the plough, and then proceed to take off the other sides of the ridges in like manner, and return it as before.

If the ground be made in good condition before sowing, a crop may be mowed in July, the produce of which will surprise any one who is not acquainted with the plant.

In September it will be fit to cut again; but if in the intermediate time weed should appear, let the hoeing

be repeated: thus the weeds will be destroyed the first year.

After the second cutting, send in the plough again, and take off the sides of every ridge within about six inches of the plants, and so let them remain till February, when the plough should return the mould to every ridge; and in May the grass will be ready for cutting, and will continue to afford a crop every month during the summer.

The hoeing should be repeated, as before directed, as often as weeds appear; but observe never to horse-hoe it when the ground has any adhesion.

The hoeing before the winter is to keep the plants dry during that season, and to meliorate the soil of the alleys by the influence and mechanical operation of the winter frosts.

To keep my letter within reasonable compass, I have been short in my directions, but to practical farmers, I hope, sufficiently plain; if not, any necessary explanation I shall cheerfully furnish.

Your readers will please to observe, that after the first preparation of the ground, if they horse-hoe the crop regularly every year, the dung which Mr. Rocque's friend recommends (as it may be got easily at, in London) may be saved for other purposes, as by this method of managing lucern, the crop and ground will be improving every year.

I appeal then to every impartial judge, whether this method is not cheaper than the ploughing, harrowing, and dunging, so warmly recommended by your correspondent. It is almost unnecessary to urge, that a crop raised in this way will, ever after the first year, be equal, if not superior to Mr. Rocque's, as the gentleman admits as large crops may be raised in the drill way.

I am a stranger to Mr. Rocque and his friend. I have no other motives in troubling you on this subject, than a public benefit to mankind, and a gratitude to the memory of Mr. Tull, whose superior ingenuity, I blush to own it, hath shone in France, to the reproach of Englishmen. And were we all to join in opinion with your correspondent (who says, "It would be well were we to improve our old practices, before we even attempt to bring the new ones into general use," we should indiscriminately merit the pity of all nations for our perverseness. Perhaps, had Tull been a foreigner, his system would have been established amongst us long ago.

The author of the former account not being satisfied with the reasons offered by his antagonist, made the following reply; which we thought necessary to insert, that our readers may judge for themselves, and follow the method that shall appear to them the most rational.

I troubled you the beginning of last year with a letter on the subject of lucern, which you were so obliging as to insert in your first volume, page 339.

I am still an advocate for Mr. Rocque's method of culture in preference to Mr. Miller's, as far as regards this plant; and that for this plain reason, because I imagine the farmer will be much more likely to adopt the first than the last: and the culture of lucern can produce very little advantage to the nation, unless it is generally adopted by the common farmers.

My reason for troubling you, or your readers, at this time, is to remind you, that Mr. Rocque's small tract, lately published, contains some particulars respecting lucern, which were not noticed in my former letter, and therefore may, with great propriety, be now laid before your readers.

The first of these particulars relates to the manner of sowing the lucern; and in this Mr. Rocque differs widely from Mr. Miller, as he thinks it should not be sown without corn; but I will give you Mr. Rocque's own words, as they carry great weight with them. "You must not sow lucern without corn, unless your spot of land is too small to use a harrow in: in that case, you must sow it in drills, and keep it very clean hoed. The drills for such small spots are to be ten inches distant; if wider, it lodges in the drills. The reason I recommend sowing corn with it is, to prevent the weeds choking it; but, you must sow only for half a crop: otherwise your corn will be apt to destroy your lucern, especially if it proves a wet season, and your corn is strong. If there is no corn sown amongst it, you must be obliged to mow the weeds, and run a chance of cutting the lucern with them: and, being very sappy, you cannot imagine how detrimental it is to bleed it when

young; but when the corn will be fit to mow, the lucern also may safely be cut."

As the duration of lucern has been a question long agitated, and not, that I know of, finally determined, it will not be amiss to mention a fact related by this able cultivator, as it will be an encouragement to the planters of lucern.

"As to the duration, it will last as long as the ground is kept clean. I saw some at Mr. Middlemar's, at Grantham, in his garden, that was forty years old; and it was very fine. To keep it thorough clean, you must harrow it every time it is mowed; and, if requisite, at Michaelmas, and in February and March. If you once leave it foul, it will be very expensive to clean. You must make use of the drill-plough: but let the harrow be ever so strong, you need not fear its hurting it."

In my letter to you, above-mentioned, it is observed, that in preparing land for lucern, a trench-ploughing would be of great advantage: but in the piece lately published, Mr. Rocque says, "In case you are not well acquainted with the state of your ground, you must trench-plough it twice, according to the directions for ploughing, which are in my Hints upon Burnet; whereby the roots will run down the sooner out of the reach of dry weather: and if the soil that is turned up be ever so sour, future ploughings, harrowings, and manurings, will sweeten it sufficiently for the reception of the seed."

Mr. Rocque adds, in this place, that "lucern will grow very well in clay land, with proviso the ground works well. The difficulty in these lands lies in the harrowing; in dry weather the ground being so very hard, the harrow can do but little good, unless you take the season between wet and dry to harrow it, which you certainly must."

It is also observed that in the province of Languedoc, in France, the inhabitants mow their lucern when it is six or seven inches high, in order to kill the annual weeds. Of this practice Mr. Rocque now says, "By my own experience, I find they are in the wrong; for it bleeds it, so that the plants make but little progress when cut so young, and are a long time in recovering it. It ought never to be cut but when in bloom."

A great many imagine that the seed might profitably be saved in England; but Mr. Rocque is of a different opinion; and indeed I am inclined to join with him in this respect, as in this island it is at best but a precarious crop, and can be imported so cheap, that the seedman can afford to retail it at nine-pence per pound, at which price it was this year advertised. Mr. Rocque's observation on this point is as follows: "In hot summers the seed may be saved in England, but not from the first growth, that being generally too rank, and subject to rot at bottom: though I think it is needless attempting to save any of the seed in England; for, in the year 1761, which was a very fine summer, I tried to save the seed of the second growth, on light land, but made nothing of it; not saving above thirty pounds of seed upon four acres and a half. I also tried, that same summer, to save some off stiff land; but that proved still worse."

I have only now to give you Mr. Rocque's thoughts on the value of this grass, which, in my opinion, deserves to be preferred to almost all others.

The Practical Cultivator says, "I have already observed, it ought not to be cut but when it is in blossom: and that is but three times a year: but after mowing the third crop, you may, instead of mowing the fourth, feed it; but when frosts come, you must take your cattle off; because there are always young shoots, which would be bruised, if the cattle were not taken off. If it is rank in September, it is dangerous for cows, being too feeding; but turn horses and sheep upon it. As there is no grass, as has yet come to our knowledge, which gives the cows so much milk, you may let them graze about an hour, at most, in the afternoon, when the dew is off. When made hay, it is likewise the best for milk: wherever it is much cultivated, they prefer it to all other kind of hay."

When I was at Monosque, a city in Provence, which was about twenty-seven years ago, the carriers fed their horses upon it, preferably to any other, without corn; and the mules looked fat and in fine order. Six mules which I hired there, to carry my seeds at Nîmes, fed on nothing else, and yet carried their load all day long, without unloading. They have the custom of hanging little bags to their

their horses or mules heads; wherein they put lucern, on which they feed as they go.

It is acknowledged by all connoisseurs to be the most feeding of all pasture, either green or in hay. I trust not barely to report, but have experienced it to be so myself. I had colonel Vernon's horse sent to me from the country, in a very poor condition; and, in fourteen days, he was in very good order. The colonel was surprised to see how he had thrived in that short space of time.

Many are apt to condemn it; but it is for want of knowing its good qualities. It has been introduced for a long series of years; but so little noticed, that one and twenty years ago there was not two hundred weight of lucern grafs seeds to be sold amongst all the seedsmen in London; and I had much ado to re-introduce it; but now, within these three or four years, there is a prodigious consumption of it.

One Mr. Beadle, a farmer in Kent, has fourteen acres of it, for which he had a premium. When I called upon him, which was in the beginning of May last, he had mowed his lucern; and sold it upon the spot, for three pounds or three guineas a load. I blamed him for cutting it so young; but he told me he was compelled to it, to get fodder for eight hundred head of sheep that he had; but that, a little while after, it grew so fast, that he could turn his sheep upon it. Those that bought this hay must needs be well acquainted with the goodness of it, to fetch it on the spot, though they were ten or twelve miles distant.

It is not foggy, like clover or tares. Horses will work with it green, as well as with hay or corn: they do not sweat with it, as they do with other green fodder. I have been told, one of our post-masters kept his horses both winter and summer with it, and that his horses were the best on the road. They object, the hay of it is difficult to make: it is no more difficult than clover. All hay is difficult to make in wet weather: but when it is a bad season to make hay, do as Mr. Allen does; put it up in ricks when dry, and between every bed of hay, of any kind, put a layer of salt, and that will recover all the damage the rain can have done.

I have done it myself, this very last year, with a rick of burnet: to about twelve loads I have put a sack of salt among it; and every time my horse comes near it, he eats it very eagerly, though he can get but at the outside of it. It will keep in ricks as long as any hay.

Multitudes, at present, are pretty well acquainted with the excellence of both these grasses: but if any doubt the truth of what I assert, let them take the trouble to enquire into it, of Mr. Shennelly, the tobaccoist, at Houndsditch; to whom I have sent a load of lucern, and am to send another load of the same, and half a load of burnet hay.

Those who are not satisfied with the theory, may be convinced of the practical part, by seeing a field of mine of lucern, of four acres and a half, at Battersea, and the manner of working the harrow."

From what has been said on the subject of lucern, I hope your farming readers will be induced to adopt the culture of it; as, if they are not blind to their interests, they cannot but be convinced of the many advantages which would result to them from so doing. Mr. Rocque's method of cultivating this plant differs but little from the manner in which they raise clover; and the profit to the landholder will be abundantly greater. *Museum Rusticum*, vol. IV. p. 259.

The following method of cultivating lucern, is extracted from a very ingenious performance, entitled, *Essays on Husbandry*; the principal intention of which is, to recommend a newly-discovered method of cultivating this plant.

Mr. Rocque, as may be seen above, has adopted the old Roman method of sowing it, broad-cast, and harrowing the land from time to time by way of destroying the weeds. Mr. Miller recommends the new, or drill husbandry, for the culture of lucern; but the author of the *Essays* above-mentioned differs from both these practical cultivators, and raises his lucern in a nursery; after which he removes the young plants, and having cut off their stalks and tap-roots, transplants them, with great regularity, into the field where they are to stand for a crop.

I shall not pretend to decide which is the best method; yet I may venture to say, that I know it may be raised to considerable profit, both in Mr. Rocque's way, and ac-

ording to the rules laid down in the new, or horse-hoeing husbandry.

I have no doubt but it may succeed by transplantation; yet I greatly fear that the expences in this method will, when applied to any considerable extent of land, greatly exceed the worth of the crop.

These *Essays* being too learned for the honest farmer's reading, it is very improbable they should ever fall into his hands; yet, as it is a great pity he should not be permitted to judge for himself in a matter which may turn out so much to his advantage, we have taken the trouble of transcribing a few pages of the second *Essay*, which more immediately treats of the culture of lucern by this new method of transplanting.

In this extract we have omitted all reasonings that might render the narration obscure to the farmer; not that we had ourselves any objection to them, or did not approve of them; but that we were willing the honest cultivator should have as much of this matter laid before his view, in a plain manner, as was necessary for him to understand it: when this is done, he may judge for himself; and if on trial he finds the method here recommended answer, his best way will be to adopt it in his future practice.

Whoever proposes to sow a lucern nursery, or engages in any larger undertaking of cultivating whole fields of saintfoin, trefoil, buck-wheat, spurrey, fenugreek, sweet melilot, &c. would be no ways ill advised, if he prepared a bit of ground, and sowed a spoonful of the seeds about a fortnight before he proposed to sow his larger quantity; since, from the good or bad success of this little attempt, he may be enabled to judge whether the seedsmen has supplied him with seeds fit for vegetation. Without such precaution, a whole year may be lost; which is a mortifying circumstance in matters of husbandry.

In the end of March, 1757, a common day-labourer was ordered to sow a pound and a half of lucern seed, and keep the ground clear from weeds. The seed was sown on one of the least promising pieces of land in all the neighbourhood; but this was done by express order; for it was thought unfair to make the experiment on a better soil than the commonest sort of grafs-fields. The spot of earth set apart for the purposes, both of nursery and transplantation, was, in former times, a kitchen-garden: but the good soil, to the depth of eighteen inches, had been removed for the sake of manuring a corn-field. [To which we shall just add, that the attempt was made in an hilly country, where the staple earth is naturally shallow.] What remained was a cold, yellow, clammy stratum, which the country people looked upon as mere clay; but as nature having since been better examined, it appears to be a mixture of imperfect clay, and imperfect marle. No manure worth mention was used upon it, as will appear by the sequel.

To all seeming appearance, little, or next to nothing, could be expected from a piece of ground of such an unpromising cast; but upon the whole, the experiment proved successful and easy.

By the middle of August, the plants were, some of them, eighteen inches high; and many of them branched out, subdivided themselves, and made very fine side shoots: upon which it was resolved to venture upon the second part of the experiment, according to the accounts given by M. de Chateaucieux; therefore taking the advantage of a moist season, in the beginning of September, (which season, by the way, did not last long) we performed the work in the following manner. But here let it be just observed, in passing along, that the time of the year, pitched upon for transplanting, was, at least, three weeks too late for England, though perhaps highly proper for the territory of Geneva, or the southern parts of France. This therefore is set down as one of the *mutatis mutandis* so indispensably necessary in matters of agriculture, when the practice of one country is copied in another.

First the roots were dug up carefully; orders being given before-hand not to attempt drawing them, even with the smallest degree of violence, till the earth was entirely loosened at top and at bottom. In the next place, the long tap-roots were cut off eight, nine, or ten inches, discretionally, below the crown of the plant (the scissars being generally applied just beneath the forks of the root, if it be a branching root): then the stalks were clipped about five inches above the crown of the plant; and the remain-

be repeated: thus the weeds will be destroyed the first year.

After the second cutting, send in the plough again, and take off the sides of every ridge within about six inches of the plants, and so let them remain till February, when the plough should return the mould to every ridge; and in May the grass will be ready for cutting, and will continue to afford a crop every month during the summer.

The hoeing should be repeated, as before directed, as often as weeds appear; but observe never to horse-hoe it when the ground has any adhesion.

The hoeing before the winter is to keep the plants dry during that season, and to meliorate the soil of the alleys by the influence and mechanical operation of the winter frosts.

To keep my letter within reasonable compass, I have been short in my directions, but to practical farmers, I hope, sufficiently plain; if not, any necessary explanation I shall cheerfully furnish.

Your readers will please to observe, that after the first preparation of the ground, if they horse-hoe the crop regularly every year, the dung which Mr. Rocque's friend recommends (as it may be got easily at, in London) may be saved for other purposes, as by this method of managing lucern, the crop and ground will be improving every year.

I appeal then to every impartial judge, whether this method is not cheaper than the ploughing, harrowing, and dunging, so warmly recommended by your correspondent. It is almost unnecessary to urge, that a crop raised in this way will, ever after the first year, be equal, if not superior to Mr. Rocque's, as the gentleman admits as large crops may be raised in the drill way.

I am a stranger to Mr. Rocque and his friend. I have no other motives in troubling you on this subject, than a public benefit to mankind, and a gratitude to the memory of Mr. Tull, whose superior ingenuity, I blush to own it, hath shone in France, to the reproach of Englishmen. And were we all to join in opinion with your correspondent (who says, "It would be well were we to improve our old practices, before we even attempt to bring the new ones into general use," we should indiscriminately merit the pity of all nations for our perverseness. Perhaps, had Tull been a foreigner, his system would have been established amongst us long ago.

The author of the former account not being satisfied with the reasons offered by his antagonist, made the following reply; which we thought necessary to insert, that our readers may judge for themselves, and follow the method that shall appear to them the most rational.

I troubled you the beginning of last year with a letter on the subject of lucern, which you were so obliging as to insert in your first volume, page 339.

I am still an advocate for Mr. Rocque's method of culture in preference to Mr. Miller's, as far as regards this plant; and that for this plain reason, because I imagine the farmer will be much more likely to adopt the first than the last: and the culture of lucern can produce very little advantage to the nation, unless it is generally adopted by the common farmers.

My reason for troubling you, or your readers, at this time, is to remind you, that Mr. Rocque's small tract, lately published, contains some particulars respecting lucern, which were not noticed in my former letter, and therefore may, with great propriety, be now laid before your readers.

The first of these particulars relates to the manner of sowing the lucern; and in this Mr. Rocque differs widely from Mr. Miller, as he thinks it should not be sown without corn; but I will give you Mr. Rocque's own words, as they carry great weight with them. "You must not sow lucern without corn, unless your spot of land is too small to use a harrow in: in that case, you must sow it in drills, and keep it very clean hoed. The drills for such small spots are to be ten inches distant; if wider, it lodges in the drills. The reason I recommend sowing corn with it is, to prevent the weeds choking it; but, you must sow only for half a crop: otherwise your corn will be apt to destroy your lucern, especially if it proves a wet season, and your corn is strong. If there is no corn sown amongst it, you must be obliged to mow the weeds, and run a chance of cutting the lucern with them: and, being very sappy, you cannot imagine how detrimental it is to bleed it when

young; but when the corn will be fit to mow, the lucern also may safely be cut."

As the duration of lucern has been a question long agitated, and not, that I know of, finally determined, it will not be amiss to mention a fact related by this able cultivator, as it will be an encouragement to the planters of lucern.

"As to the duration, it will last as long as the ground is kept clean. I saw some at Mr. Middlemar's, at Grantham, in his garden, that was forty years old; and it was very fine. To keep it thorough clean, you must harrow it every time it is mowed; and, if requisite, at Michaelmas, and in February and March. If you once leave it foul, it will be very expensive to clean. You must make use of the drill-plough: but let the harrow be ever so strong, you need not fear its hurting it."

In my letter to you, above-mentioned, it is observed, that in preparing land for lucern, a trench-ploughing would be of great advantage: but in the piece lately published, Mr. Rocque says, "In case you are not well acquainted with the state of your ground, you must trench-plough it twice, according to the directions for ploughing, which are in my Hints upon Burnet; whereby the roots will run down the sooner out of the reach of dry weather: and if the soil that is turned up be ever so sour, future ploughings, harrowings, and manurings, will sweeten it sufficiently for the reception of the seed."

Mr. Rocque adds, in this place, that "lucern will grow very well in clay land, with proviso the ground works well. The difficulty in these lands lies in the harrowing; in dry weather the ground being so very hard, the harrow can do but little good, unless you take the season between wet and dry to harrow it, which you certainly must."

It is also observed that in the province of Languedoc, in France, the inhabitants mow their lucern when it is six or seven inches high, in order to kill the annual weeds. Of this practice Mr. Rocque now says, "By my own experience, I find they are in the wrong; for it bleeds it, so that the plants make but little progress when cut so young, and are a long time in recovering it. It ought never to be cut but when in bloom."

A great many imagine that the seed might profitably be saved in England; but Mr. Rocque is of a different opinion; and indeed I am inclined to join with him in this respect, as in this island it is at best but a precarious crop, and can be imported so cheap, that the seedsman can afford to retail it at nine-pence per pound, at which price it was this year advertised. Mr. Rocque's observation on this point is as follows: "In hot summers the seed may be saved in England, but not from the first growth, that being generally too rank, and subject to rot at bottom: though I think it is needless attempting to save any of the seed in England; for, in the year 1761, which was a very fine summer, I tried to save the seed of the second growth, on light land, but made nothing of it; not saving above thirty pounds of seed upon four acres and a half. I also tried, that same summer, to save some off stiff land; but that proved still worse."

I have only now to give you Mr. Rocque's thoughts on the value of this grass, which, in my opinion, deserves to be preferred to almost all others.

The Practical Cultivator says, "I have already observed, it ought not to be cut but when it is in blossom: and that is but three times a year: but after mowing the third crop, you may, instead of mowing the fourth, seed it; but when frosts come, you must take your cattle off; because there are always young shoots, which would be bruised, if the cattle were not taken off. If it is rank in September, it is dangerous for cows, being too feeding; but turn horses and sheep upon it. As there is no grass, as has yet come to our knowledge, which gives the cows so much milk, you may let them graze about an hour, at most, in the afternoon, when the dew is off. When made hay, it is likewise the best for milk: wherever it is much cultivated, they prefer it to all other kind of hay.

When I was at Monosque, a city in Provence, which was about twenty-seven years ago, the carriers fed their horses upon it, preferably to any other, without corn; and the mules looked fat and in fine order. Six mules which I hired there, to carry my seeds at Nimes, fed on nothing else, and yet carried their load all day long, without unloading. They have the custom of hanging little bags to their

their horses or mules heads; wherein they put lucern, on which they feed as they go.

It is acknowledged by all connoisseurs to be the most feeding of all pasture, either green or in hay. I trust not barely to report, but have experienced it to be so myself. I had colonel Vernon's horse sent to me from the country, in a very poor condition; and, in fourteen days, he was in very good order. The colonel was surprised to see how he had thrived in that short space of time.

Many are apt to condemn it; but it is for want of knowing its good qualities. It has been introduced for a long series of years; but so little noticed, that one and twenty years ago there was not two hundred weight of lucern grass seeds to be sold amongst all the seedsmen in London; and I had much ado to re-introduce it; but now, within these three or four years, there is a prodigious consumption of it.

One Mr. Beadle, a farmer in Kent, has fourteen acres of it, for which he had a premium. When I called upon him, which was in the beginning of May last, he had mowed his lucern, and sold it upon the spot, for three pounds or three guineas a load. I blamed him for cutting it so young; but he told me he was compelled to it, to get fodder for eight hundred head of sheep that he had; but that, a little while after, it grew so fast, that he could turn his sheep upon it. Those that bought this hay must needs be well acquainted with the goodness of it, to fetch it on the spot, though they were ten or twelve miles distant.

It is not foggy, like clover or tares. Horses will work with it green, as well as with hay or corn: they do not sweat with it, as they do with other green fodder. I have been told, one of our post-masters kept his horses both winter and summer with it, and that his horses were the best on the road. They object, the hay of it is difficult to make: it is no more difficult than clover. All hay is difficult to make in wet weather: but when it is a bad season to make hay, do as Mr. Allen does; put it up in ricks when dry, and between every bed of hay, of any kind, put a layer of salt, and that will recover all the damage the rain can have done.

Multitudes, at present, are pretty well acquainted with the excellence of both these grasses: but if any doubt the truth of what I assert, let them take the trouble to enquire into it, of Mr. Shennelly, the tobacconist, at Hound-ditch; to whom I have sent a load of lucern, and am to send another load of the same, and half a load of burnet hay.

Those who are not satisfied with the theory, may be convinced of the practical part, by seeing a field of mine of lucern, of four acres and a half, at Battersea, and the manner of working the harrow."

From what has been said on the subject of lucern, I hope your farming readers will be induced to adopt the culture of it; as, if they are not blind to their interests, they cannot but be convinced of the many advantages which would result to them from so doing. Mr. Rocque's method of cultivating this plant differs but little from the manner in which they raise clover; and the profit to the landholder will be abundantly greater. *Museum Rusticum*, vol. IV. p. 259.

The following method of cultivating lucern, is extracted from a very ingenious performance, entitled, *Essays on Husbandry*; the principal intention of which is, to recommend a newly-discovered method of cultivating this plant.

Mr. Rocque, as may be seen above, has adopted the old Roman method of sowing it, broad-cast, and harrowing the land from time to time by way of destroying the weeds. Mr. Miller recommends the new, or drill husbandry, for the culture of lucern; but the author of the *Essays* above-mentioned differs from both these practical cultivators, and raises his lucern in a nursery; after which he removes the young plants, and having cut off their stalks and tap-roots, transplants them, with great regularity, into the field where they are to stand for a crop.

I shall not pretend to decide which is the best method; yet I may venture to say, that I know it may be raised to considerable profit, both in Mr. Rocque's way, and ac-

ording to the rules laid down in the new, or horse-hoeing husbandry.

I have no doubt but it may succeed by transplantation; yet I greatly fear that the expences in this method will, when applied to any considerable extent of land, greatly exceed the worth of the crop.

These *Essays* being too learned for the honest farmer's reading, it is very improbable they should ever fall into his hands; yet, as it is a great pity he should not be permitted to judge for himself in a matter which may turn out so much to his advantage, we have taken the trouble of transcribing a few pages of the second *Essay*, which more immediately treats of the culture of lucern by this new method of transplanting.

In this extract we have omitted all reasonings that might render the narration obscure to the farmer; not that we had ourselves any objection to them, or did not approve of them, but that we were willing the honest cultivator should have as much of this matter laid before his view, in a plain manner, as was necessary for him to understand it: when this is done, he may judge for himself; and if on trial he finds the method here recommended answer, his best way will be to adopt it in his future practice.

Whoever proposes to sow a lucern nursery, or engages in any larger undertaking of cultivating whole fields of saintfoin, trefoil, buck-wheat, spurrey, fenugreek, sweet melilot, &c. would be no ways ill advised, if he prepared a bit of ground, and sowed a spoonful of the seeds about a fortnight before he proposed to sow his larger quantity; since, from the good or bad success of this little attempt, he may be enabled to judge whether the seedsmen has supplied him with seeds fit for vegetation. Without such precaution, a whole year may be lost; which is a mortifying circumstance in matters of husbandry.

In the end of March, 1757, a common day-labourer was ordered to sow a pound and a half of lucern seed, and keep the ground clear from weeds. The seed was sown on one of the least promising pieces of land in all the neighbourhood; but this was done by express order; for it was thought unfair to make the experiment on a better soil than the commonest sort of grass-fields. The spot of earth set apart for the purposes, both of nursery and transplantation, was, in former times, a kitchen-garden: but the good soil, to the depth of eighteen inches, had been removed for the sake of manuring a corn-field. [To which we shall just add, that the attempt was made in an hilly country, where the staple earth is naturally shallow.] What remained was a cold, yellow, clammy stratum, which the country people looked upon as mere clay; but as nature having since been better examined, it appears to be a mixture of imperfect clay, and imperfect marle. No manure worth mention was used upon it, as will appear by the sequel.

To all seeming appearance, little, or next to nothing, could be expected from a piece of ground of such an unpromising cast; but upon the whole, the experiment proved successful and easy.

By the middle of August, the plants were, some of them, eighteen inches high; and many of them branched out, subdivided themselves, and made very fine side shoots: upon which it was resolved to venture upon the second part of the experiment, according to the accounts given by M. de Chateaucieux; therefore taking the advantage of a moist season, in the beginning of September, (which season, by the way, did not last long) we performed the work in the following manner. But here let it be just observed, in passing along, that the time of the year, pitched upon for transplanting, was, at least, three weeks too late for England, though perhaps highly proper for the territory of Geneva, or the southern parts of France. This therefore is set down as one of the *mutatis mutandis* so indispensably necessary in matters of agriculture, when the practice of one country is copied in another.

First the roots were dug up carefully; orders being given before-hand not to attempt drawing them, even with the smallest degree of violence, till the earth was entirely loosened at top and at bottom. In the next place, the long tap-roots were cut off eight, nine, or ten inches, discretionally, below the crown of the plant (the scissars being generally applied just beneath the forks of the root, if it be a branching root); then the stalks were clipped about five inches above the crown of the plant; and the remain-

ing plant, after these amputations (which may appear, at first sight, to be very bold ones) was thrown into a large vessel of water which stood by for that purpose, in the shade. Such refreshment is no ways unnecessary; for this plant is very impatient of heat and sun-shine after it is taken up; nay, to such a degree, (at least the first half year of its growth) that one may almost call it a sensitive plant. The same day, making use of a dibble, or setting-stick, and filling every hole with water before the roots are put in, we transplanted them in rows, two feet asunder, and each plant six inches apart in the rows; having first made little drills, or channels, and sprinkled, or half filled them with sea-sand and wood-ashes kept dry (two parts of the former to one of the latter); which was done with a view of loosening the soil, and giving a little warmth to a piece of ground which was naturally cold and clayey; nor was any other manure used. The drills were afterwards once watered, to take off the dryness and heat of the ashes. The roots were placed firmly in the ground, and two inches of the stalks covered with mould.

Yet here it must be freely acknowledged, that the hopes of possessing a large crop occasioned one mistake, which we chose rather to mention than suppress, as many people may happen to entertain the same false expectancies. The mistake was, that we made our rows two feet asunder, which was over-narrow; and placed the plants, in the lines, only six inches apart, which brought them nearer together than they ought to have stood, even though the ground was very poor: nor did we foresee, that horse-hoe ploughing is five times more efficacious, as well as cheaper, than hand-hoeings.

Therefore, after frequent experiments, since made, it appears best to make the lines three feet four inches distant from each other: and if the soil be good, it may not be amiss to allow each plant a foot distance one from another in the lines, for thus the hand-hoers will work more commodiously, and a little hoe-plough may be guided safely up and down the intervals, which will save a great deal of trouble; nor will the future crops be lessened, by such thin transplanting, half so much as may be imagined; but, on the contrary, the plants will be larger, more juicy, and better tasted; which circumstance may be extended in favour of the New Husbandry in general. Space and culture improve the herbage and seeds of plants; in proof whereof I have been assured, from good authority, that all the corn, raised by M. de Chateauvieux, sells at an advanced price; being larger, brighter, and healthier than common corn, and, consequently, more fit for sowing, or making bread.

But, by way of confirming the necessity of allowing lucern roots a good share of space, a friend of the author's filled an acre with plants, according to the first directions; but the soil proving extremely good, and free from weeds, it soon appeared that the roots stood too close; in consequence whereof, every other plant was taken up the next autumn, and a fresh acre of land being properly prepared to receive them, he thus gained a new plantation of lucern, at a small expence, with little trouble; and what is more remarkable, it is thought the second acre bore a larger quantity of herbage than the first would have done, if the plants had continued as they were, without being thinned, to the amount of one half. Of course, there is reason to conclude, that this slight hint, which took its rise from mere accident, ought not to be looked upon as quite unuseful, since two acres may be raised with almost the same expence as a single acre.

In ten days, though a drought succeeded, some transplanted plants made shoots of three inches height: which vigorous growth gave better hopes than had been conceived at first.

It was also some encouragement to the undertaker, that he found wild lucern within two musket shots of the place where the nursery was formed. These plants were certainly *aborigines*; for they grew in a part of the kingdom where the name of lucern had rarely been heard of, except by gentlemen. Besides, no person curious in husbandry would have ventured sowing the seeds in such an unpromising piece of ground; for the field, where the wild lucern grew, was a sort of coarse uncultivated morass, and valued only at about two shillings and sixpence an acre.

Yet still the approach of winter made many persons doubtful concerning the success of this new plantation; nevertheless, it was some satisfaction to recollect, that there is less harsh, severe cold in England (and that almost by

one third) than in the territory of Geneva, where the original experiment was made, and where the plant we are speaking of has been known to thrive so extremely well.

At length the winter passed over, and, out of four thousand roots, only thirty or forty perished, whether by frosts, immoderate rains, or any other accident, is hard to say; but the labourer filled up all the vacant spaces from the nursery in about an hour, and in April, 1758, most of the plants were nearly equal in size and strength; of a deep juicy verdure, with few or no discoloured sickly leaves; but, May the 8th, people counted sixty stems from one particular root, and the stalks and leaves of some chosen plants weighed near half a pound at one cutting. Yet we learn, by experience, that lucern must only be considered as in a progressive state, till the third summer after transplanting; and then, M. Duhamel assures us, that one flourishing plant will produce a pound of well-dried hay; which is saying a great deal, and much more than I could ever verify; for if a single plant produces one pound of hay, it must have weighed four pounds when it was green. Yet I have received an account from an eminent physician in our own country, (who planted two acres of lucern by my directions) that many of his plants, in the second year, yielded near half a pound of hay each plant.

As an acre of lucern, thus managed, will contain more roots than one is apt to imagine at first guess, how great must the produce be of four or five cuttings every year, and those confessedly the most nourishing and palatable food that cattle can eat! For thus much is certain, amongst other advantages, that, if a field be industriously hoed, ploughed in the intervals and spaces, and hand-weeded in the rows, for the first two or three years, it is almost sure, that horses, cows, or sheep, will hardly find a single weed in a large quantity of green food.

We will now mention the state of our transplanted lucern in its second year, namely, 1758.

And here let it be remembered, that what cultivators call a proper time for cutting is, when the plants are about fifteen or sixteen inches high, at an average, throughout the field; but this must be understood in a relative sense, for some plants will be two or three feet high, and others may not be above ten inches, or one foot, in height, according to the circumstances of health, space, situation, &c. of the several roots.

The cuttings of the year 1758 were as follow: May 8th, June 7th, July 12th, August 20th, and October 1st.

In the year 1759, it was cut five times, and six times in 1760; which made sixteen cuttings in three years. Nay by the 9th of April, in 1760, some of the lucern plants were near seventeen inches high, at a time when no field in the neighbourhood had grass of four inches height, though you took five or six acres together. The same lucern was cut twice, before any hay-making began in the country round it, if we except some few meadows lying near market-towns.

Having carried on my first experiment thus far, upon almost as unpromising a piece of land as could be found, and being sensible I had made some mistakes from want of experience (having as yet never seen any transplanted lucern in England), I gave directions for making a small plantation in Berkshire, but still took care to choose a field that could hardly be called middling land. It was overrun with coarse weeds, had been long out of tillage, and the earth in most places was hardly four inches above a bed of chalk; which (let farmers say what they please of it, in respect to *saintfoin*) is no ways favourable to the growth of lucern, especially if the latter be transplanted; for the chalk flakes, when thaws and rains come on; and it either heaves the plants out of the ground, or exposes the fibres of the roots too much to the cold. Yet upon this I ventured with my eyes open; for Pliny (whose authority I scruple not to take, when I have no other) had given me a caution concerning lucern raised upon chalky lands; but what induced me to make the attempt was, that the goodness of the soil might not lead me to say more concerning the success of an experiment than other people may hope to find.

The little field, or close, consisted of one rood of ground, or a quarter of an acre; which we threw into fifty-four rows, each row containing one hundred and ten plants, or five thousand nine hundred and forty in the whole. In the second year after transplanting, (and lucern is not then arrived to its due size), and at the first annual cutting, (which

(which is not the best cutting, as the herbage suffers much from the winter) I weighed, out of curiosity, a parcel of the prime plants, which, one with another, weighed about one pound and a quarter each. But supposing that every plant weighed only one quarter of a pound, and admitting we give up the sixth cutting, (which is more than one needs to do) then the crop of forty perches, or one fourth of an acre, amounts to a very considerable return of ten tons, at least, of green lucern per acre.

An acre of transplanted lucern, rightly managed, will bring in five pounds a year, free and clear from all expences, and that for a considerable tract of time. Now certainly this advantage deserves well to be considered; for the husbandman is said to be a good manager who makes three rents each year; a first for the landlord, a second for the labour, &c. and a third for himself: but an acre of lucern will for several years produce five rents, clear of all out-goings for rates, rent, workmen, manure, &c. supposing the land to be let at fifteen shillings an acre, as usually happens in most estates that lie at some distance from cities and market towns. On the contrary, if land be dearer near rich populous places, the ground will be better, and the produce more advantageous. This gives lucern its value near towns and cities, where two or three acres may be rented: but ten or twenty cannot; and sure it is some advantage in husbandry to make one acre supply the place of two or three, and especially where it is difficult to rent land, even at a very high price.

It is certain, that the profits arising from transplanted lucern have been no ways exaggerated in my account; for by some collateral observations, it may be easy to carry the value of an acre something higher than has been here represented. Suppose green vetches (which are rarely cut more than once) and green lucern to be of equal value as food for horses (which is making a supposition no good writer in husbandry will allow to the disadvantage of lucern); now a perch of green vetches (if the crop be good) sells for sixpence at seventy miles distance from London, and a perch of transplanted lucern will weigh as much, or very nearly as much, at two cuttings, out of the four or five annual cuttings; which (every circumstance being duly considered) brings an acre of lucern (to say the least of its advantages in husbandry) to be of equal value with two acres and a half of vetches; not to mention that lucern is a perennial plant, and vetches are annual; which, upon the whole, makes another difference in point of profit.

As I think it unfair to suppress any unsuccessful circumstances in matters of husbandry, I will here ingenuously confess, that the most material of my mistakes were these: I followed my foreign instructions (which, at that time, were but few) with too much diffidence, and in too literal a manner. I was not enabled, through want of experience, to adapt the husbandry practices of other nations to the English climate. I transplanted too late, filled my rows too full, and allowed not sufficient space for the intervals. By following the French directions over closely, I cut the tap roots too short in the best plants, and knew not (as it is a point unmentioned by any cultivator of lucern) how to manage a root that was very small. The means of avoiding and rectifying all which mistakes and difficulties, are by the help of subsequent experience, carefully pointed out.

And here it may be worth considering how to apply a field of lucern, carefully and industriously cultivated, to the greatest advantage. In such a case, let us suppose the plantation to consist of two acres, and that four large horses are to be supplied with green fodder, from the end of April till Michaelmas. Now in order to manage this affair with dexterity, count the number of rows or lines in the lucern field, and place in one of the head-lands thirty land-marks, at equal distances; and thus, having cut a proper portion, day by day, you will be ready to begin afresh, after the last cutting.

When I say you will be ready to begin afresh at the end of thirty days, I must desire to be understood, with a small degree of latitude: for physical accidents are so numerous and unavoidable in regard to the growth of plants, (though lucern is liable to fewer checks and miscarriages than most other cultivated field vegetables) yet still the nature of the thing will not allow us to predict the time of each and every periodical cutting with much certainty; nevertheless, thus much may be depended upon, even for some years successively, that, after the first annual cutting, our di-

rections, here given, will be attended with no inconvenience to the owner; for there will rarely be more than three or four days difference between the times of the second, third, and fourth cuttings: nor will the want of lucern fodder, during such short intervals, be of the least ill consequence; for, surely, that husbandman must be a very improvident manager who has not other grass fields by way of a momentary supply.

The times, therefore, of the second, third, and fourth annual cuttings, are tolerably certain; but the first cutting, according to the nature of the winter, may be accelerated or retarded a fortnight, three weeks, and, perhaps, a month.

The time of the fifth cutting is also, in some degree, variable and uncertain, as the solar heat decreases, and the days grow shorter. A sixth cutting, which is seldom of much consequence, chiefly depends on a fortunate season, in conjunction with the industrious good management of the cultivator.

From this succession of fresh green food appears one singular advantage in raising lucern: and in the next place care must be taken, that your plantation be always proportionable to your number of cattle; or, in other words, let it be a rule with you to have rather over much lucern, than too little; for then one cutting may be set apart for hay, which may be given occasionally to favourite horses and sick cattle. But, in case no hay is made, the owner of the ground, even then, by means of the supplies he derives from green lucern, will be enabled to spare a large quantity of other grass for hay-making; and thus two acres of lucern will give him the power of saving two or three tons of hay more than he could have saved otherwise; consequently lucern, in effect, helps to keep cattle both in winter and summer.

By such sort of husbandry, and provident management, the stock of hay for winter will be considerably increased, and the owner enabled, for the space of five months at least in the other parts of the year, to allow his horses very nearly the same quantities of green food each day; all equally fresh, wholesome, and well tasted: which single circumstance, (if it related to horses only) gives lucern the preference over all other sorts of green fodder hitherto known, and in process of time may be applied (as has been experienced with much success) to the fattening of horned cattle, provided such cautions are used as shall be specified hereafter, and which ought always to be remembered. Now whatever increases the number of cattle, augments the quantity of dung necessary for carrying on the more successful cultivation of arable lands; and whatever, by multiplying the number of cattle, affords more animal food to man, will of course contribute towards lessening the price of meat, which will assist society in general, and more particularly the manufacturer and peasant; for the grand secret of well managing a trading populous country, is to supply the inhabitants with flesh and corn upon easy terms; for then mankind will multiply of course (supposing the government to be mild and equal); nor will other nations undersell us in the commodities we export to foreign markets.

Now lucern, in matters of husbandry, comes the nearest of any article yet known, towards attaining the points here proposed; forasmuch as one acre of land, thus cultivated, will support as many cattle in spring, summer, and a part of autumn, as four acres of common, natural, upland grass did before. But this use of lucern is greater, if land be scarce; or if the nation be populous, and the soil has been cultivated to the extent of the old husbandry: for then the introducing this plant is, in effect, the same as creating new land, if the superior produce of lucern, both in quantity and quality, be fairly considered by us.

Yet one thing must be well understood in the new practice of raising lucern. Negligent husbandmen, and such as expect good crops without labour, expence, frequent ploughings, weedings, &c. would act a wise part in not attempting to cultivate the plant here mentioned: nor is it advisable for gentlemen of fortune to commit this part of husbandry to bailiffs and servants, who (be their master's advantage ever so great) will not like the labour (though they were well paid for it) of turning fields into a sort of gardens, and, besides all this, may conceive a prejudice against improvements, and take some small delight to see them miscarry: so that all random, careless, and insincere methods of culture, must have nothing to do with raising plants, which, though hardy and long-lived after they at-

tain a certain age, yet are surprizingly delicate and tender when they are young, or when first transplanted; and more especially if wild couch-grass and other weeds should spring up amongst them.

For these reasons, at first setting out, I must advise every good cultivator to be particularly industrious in the extirpation of weeds, and that he overburdens not the strength of the earth from a principle of avarice, but allows her the just refreshments of manures, and gives her at least some breathing space of ease and repose.

It is highly unreasonable to expect success in the management of this plant without care, and highly improbable (if the seeds are good) to miscarry with due care. It is true, many people have failed in the process of this experiment; but then one is generally enabled to point out the error, as likewise the cause of ill success, with tolerable exactness. To begin well in cultivating this plant is doing but little; rules and directions must be cautiously observed for three, or two years at least. Few people make mistakes in the beginning of an experiment: but, generally speaking, after three or four months are expired, the master's attention and keenness wear off, and the bailiff or gardener, (as sometimes the raising of a lucern nursery falls in the province of the latter) are extremely glad not to refresh his memory: for the one does not like an additional trouble out of his department, (a punctilio which has great weight with all servants); and it is a maxim with the other, never to admit any thing new in matters of husbandry, but admire those sorts of crops which Columella describes, crops that can hold up their heads, and prosper under all the negligence of a pretending cultivator.

It is true, many difficulties and discouragements attend making experiments. The continuance of life is as short as that of art is permanent; and few husbandry experiments can be made oftener than once in a year: nor must we reason too much by analogy, from success in one production, to success in another of a different species. Attention also is required, and that even to the minutest circumstances: and again, too many experiments die with the observer; which, though highly useful, did not appear considerable enough for human vanity to establish a system thereon.

Yet still all these difficulties and discouragements may be counter-balanced by the advantages which result afterwards to society.

Lucern cannot easily be freed from manifest disadvantages by any other method of culture than what is here recommended. That it has usually miscarried, when sown with spring corn, after repeated trials in this kingdom, from the year 1757 to 1764, is well known to many readers; for common wild grass, and particularly couch-grass, may be called its destruction, if not its poison, principally indeed by starving the roots of it, but probably from its effluvia too. This likewise I have always observed in plants of a different species that stand too near each other; they immediately, as it were by a declaration of war, contend for mastery: the roots are constantly attempting depredations and encroachment upon each other; whilst the stalks, especially those of weeds, make the same efforts in longitudinal shoots; and that plant which overtops the other, provided the shoots are equally thick and strong, always gains the victory, and, by overshadowing and dripping upon its antagonist, forces it to dwindle away and perish. This struggling for life and mastery draws up the plants too weak and spindling, and the conquered plant usually dies. Now weeds, generally speaking, are more hardy, savage, and hungry, than manured vegetables. If such be the case, where is there a country to be found that abounds with foul grass and weeds more than England? So that, if lucern be sown in the usual way amongst corn, like ray-grass, clover, and hop-trefoil, no care can keep an acre clean. It may last two years, (only one crop being tolerable) and then must perish in the common course of nature. A gentleman very lately made this experiment (in a great degree against his judgment) for the sake of farmers, in hopes of finding out a cheap, easy, and compendious method of raising lucern; but the crop at the end of fifteen months was as near being overpowered and starved as can be imagined; which made him venture to take up and transplant the few good roots that remained, which, being freed from the bad neighbourhood and incumbrance of coarse grass and other weeds, appeared to prosper very well. Again, if lucern be raised in drills according to

the best directions hitherto given by our ingenious countrymen, Tull and Miller, (who, to do them justice, were the first persons, amongst our modern writers, that saw the great advantage of this grass, and pressed the culture of it strongly on the English nation); certain it is, that such a method will greatly exceed the promiscuous sowing of lucern with spring-corn. Yet still, in the practice of drilling, a considerable part of the seeds may be faulty, and then the rows will appear naked and unsupplied with herbage: nor can the hopper be supposed always to drop the little grains at precise distances, plant from plant. Nevertheless, such persons as prefer drilling may fill up all the vacant spaces with transplanted roots.

In the method of cultivating lucern, which is here recommended, an acre will be found to contain about such a number of chosen healthy roots as the ground is capable of supporting, and admit a greater number of them than the reader will be apt to imagine, *prima facie*; for it will hold, according to my first experiment, about twenty-six thousand plants: but, if the ground be clean, rich, and well conditioned, it may be more advisable to observe the greater distances already mentioned; upon which principle, the acre will contain about thirteen thousand plants; and this is the number, all things considered, I am most inclined to recommend; for the produce of such an acre will be full as large and profitable as the former, and the ground will be managed with less expence and more convenience.

It may be observed farther, that, in transplanting lucern, there will be one advantage (and that no small one) which can never be obtained in drilling, or promiscuous sowing; each root will stand at a proper distance from its neighbour, and receive its allowance of food in due quantity without diminution. In the next place, you will seldom see a plant wanting, and rarely (except by mistake) a plant supernumerary: but, if a few sets should chance to die, it will be easy to supply the vacant spaces from the nursery, and that as people find by experience, in any moist day, from April till the middle of September.

There is another advantage which arises from transplanting lucern; for, by cutting the tap-root, you prevent its penetrating ten or twelve feet perpendicular into the ground, which the plant naturally does in three or four years, except it be obstructed by a stratum of rock, or chilled at root by weeping springs, or finds admission in a bed of cold watery clay. Then the crop makes a poor appearance, or, perhaps, goes off all at once.

People who hand-hoe or horse-hoe lucern, need not give themselves much pains about breaking or cutting off a lateral root accidentally, not but that some care and caution must always be used; however, what seems to injure the parent-plant, proves in the end no ways disadvantageous to it: for horizontal, or side roots, thus cut, or broken, push forth new roots and filaments laterally; and thus the suckers, or tubes that suck nourishment, are multiplied by a cause which had the appearance of lessening their number. Yet transplanted lucern will no ways bear such rude treatment as the ancients sometimes gave to untransplanted lucern, when they thought fit to make it undergo the discipline of harrowing.

How long lucern may last cannot be known by the experiments which are here related, namely, from the spring of 1757, to the beginning of the year 1764; but some persons of credit have observed the plants to continue in good strength and health near twenty years. [I suppose they mean here and there particular plants, and not a whole plantation.] Tull, indeed, tells us that, except lucern be choked or starved by grass and weeds, he hardly knew when to say it will die a natural death; and probably it may not prove the less long lived for being transplanted; since hand-hoeings, horse-hoeings, and digging will give new strength and health to the plants. The spreading of the roots will be facilitated by loosening the soil, and letting in the good influences of the atmosphere; their growth also will be augmented by giving them that additional nourishment of which the weeds defrauded them: and, in the last place, all manures will more easily reach them; for thus much is a certain fact in husbandry, that, when the ground is rendered clean, light, and penetrable, the roots love to expand themselves, in order to procure a greater quantity of nourishment.

I fairly acknowledge that I am not enabled, from my own experience, to fix the common duration of lucern, whether

whether transplanted or drilled, (and that from no difficulty in the thing itself, but because a sufficient number of years has not elapsed since making my experiments); but thus much I can take upon me to say, from my own knowledge, that lucern sown at random, or by what we call promiscuous sowing, as the ploughman sows rye-grass and clover, (whether with or without spring corn) will not last to any tolerable purpose above two years, or three at most. But as this plant is of the greatest use and value, where land is dear, and scarce, as near cities and towns, I see no reason to doubt, but that the same spot of ground may be continued as a lucern plantation for half a century at least; for if the rows are three feet four inches wide, (which I look upon to be a *sine qua non*) then, whenever the old lucern decays, new lines may be planted in the middle of each interval which has lain fallow, and also been manured and pulverised for a considerable number of years; and thus progressively, *vice versa*, to a long continuance.

Not being able therefore to give positive satisfaction concerning the continuance of lucern rightly managed, I shall propose something that is not merely a query, and which, perhaps, may give the reader an equivalent information. In a few words, it is as follows: when lucern is grown old, and the owner proposes to break up the plantation, layers might be made from all the principal stalks, and removed into fresh ground. These layers, in all probability, may succeed extremely well, according to some few experiments made abroad in the years 1755 and 1756.

As to the expence and risque of cultivating small quantities of ground, agreeably to the method here laid down, it is to be hoped that curious gentlemen will not be deterred by some few minute difficulties or objections, but give the present experiment fair, patient, and repeated trials; for neither the out-goings nor the hazard will be very considerable. But at present it is no ways our intention to persuade farmers (at least such as are in low circumstances) to quit their little certainty for an advantage which may appear to them quite uncertain.

Let them wait, at least for a few years, in hopes some cheaper and more compendious method may be discovered for their sakes; and if, at present, they make any experiments, let them be in small portions.

The first point of consideration, when I undertook to recommend transplanted lucern to the public, from my own experiments, was to bear constantly in mind whether the profit counterbalanced the expences and labour of culture, and that in a double or even treble proportion; since, otherwise, I was doing little more than postponing utility, for the sake of introducing a new sort of husbandry, which only deserved to be called ingenious.

We all know that the farmer expends much money, and gains very little from a crop of wheat at the expiration of his twelve months; but if we take ten years together, and compare the profits of lucern on the one hand, and wheat, barley, oats, and clover, on the other, the balance will certainly turn in favour of the lucern-crops, and that in a proportion of three, or two, to one, at least.

The expence of raising an acre of lucern in the manner which we recommend, (and supposing even digging to be made use of instead of ploughing) amounts, as nearly as I can remember, to the following sums:

	l.	s.	d.
Fine-digging and picking thirty perches for a nursery	0	12	0
Seed	0	7	0
Hand-weeding the nursery twice, and transplanting into vacant patches such plants as stand too thick	0	13	0
Digging an acre for receiving the roots	2	10	0
Transplanting	1	5	0
Hand-weeding and hand-hoeing the rows, with a four-inch hoe that cuts downwards, and then with a larger plantation-hoe which cuts horizontally	1	0	0
Two horse-hoeings	0	5	0
Total	6	12	0

"It is true, the expences of raising lucern, in this manner, will vary, when applied to parts of England different from those where the experiment was made, as the price of

labour may be dearer, and rents run higher; but then the ground ought to prove better, which will balance the difference.

This plantation of lucern may be cut three times the first year after transplanting; as some repayment for the out-going expences: next year the profit will be more considerable.

On the other hand, those who prefer the drill-method of raising lucern, as less expensive, may seem to save about two pounds, or more, upon an acre, at the first appearance of things; but then the rows, in case the crop succeeds (which is a doubtful point) must be thinned with good judgment, which will cost money; and the vacancies in them must be filled at last with transplanted roots: nay, M. de Chateauvieux asserts, that drilled lucern will rarely be so large and flourishing as the transplanted; for the effects of horse-hoeing, and the influence of manures, may prove of less service to the roots of the former, at a depth of twelve or thirteen feet, than to the roots of the latter, whose finest imperceptible fibres will hardly descend above a yard perpendicular.

It is hard to say at what precise time the assistance of the hoe-plough should be called in: but the owner of the plantation may venture on the attempt, I think, with safety, in three days after the second cutting, about the beginning of June; for the roots then will be tolerably well settled in the ground, and before that time the flat plantation-hoe may be used, choosing such an one as is about eight inches and a half wide in the cutting part.

As continued hand-hoeings will be chargeable, troublesome, and almost endless (being in truth little more than a temporary expedient, and slight scratching the surface of the earth), remember to make a light plough, with which you are to cultivate the spaces between the rows; and in this case you may either invent a plough according to your own fancy, or copy such as are used at home, or in other countries, on the like occasion.

The share of this plough should be sharp, about sixteen inches long, with a coulter proportionable; the plough itself no heavier than a strong lad of fifteen years of age can carry: and thus one horse, after some obstructions of no great consequence in the first attempt, will afterwards draw it with ease. Yet still the trouble will be lessened, if the field be prepared by digging and picking up the roots and stones, instead of common ploughing, just before the ground is to receive the transplanted roots; therefore, after a full second consideration, the former practice is recommended preferable to the latter; and if the lucern stands nine or ten years, the difference of the expence will not be perceived.

As the rows will be one yard four inches asunder, there will be room sufficient to guide the plough safely along the intervals, and yet no room to spare: it behoves the ploughman therefore to be extremely careful in the slice he cuts next the lines: such a stroke must be a shallow and a dexterous one, nor must he approach too nearly. A man, an horse, and a boy to lead the horse, will manage an acre in a day, when they know their business; for it is more a matter of nicety than fatigue, since the ground ploughed in an acre will hardly exceed half an acre.

After the first time of using the horse-hoe plough (which a man's own discretion, upon considering the strength of the plants, will best determine), it may be laid down for a general rule, that it will be always found most convenient to horse-hoe the intervals (as long as the plantation stands) the third day after each cutting; for by that time the new shoots will make the plants visible, nor will any side-branches stand in the plough's way.

It may be proper also to hand-weed the lines once a year; and the larger weeds may be taken up expeditiously with the three-pronged spade or the field-spade.

We will now consider the expences of an acre of lucern the second year, which will stand as follow:

	l.	s.	d.
Clearing the lucern plants from weeds in the rows by hand	0	8	0
One hand-hoeing of the intervals	0	8	0
Four horse-hoe ploughings	0	11	0
Compost-dressing for manure, or foot, or wood, peat ashes, at an average per year	0	10	0
Dispersing the manure	0	3	0
Total	2	0	0
Such			

Such will be the yearly charges, or in some proportion very like them, during the continuance of your lucern, which I fix at a medium of ten years: M. de Chateauvieux says it may last twenty; and Pliny goes as far as thirty; though the expression may be looked upon to be exaggerated.

In regard to manuring lucern, it may suffice to suggest here in general terms, that if the ground be stiff, cold, and of a clayey tendency, then wood-ashes, foot, and lime, are proper dressings. If the ground be hot, shallow, and brashy, a compost of calcined clay, dung rotted to a fine mould, and pond-mud, long exposed to sun and frosts, and frequently turned, may have its use: and if the ground proves of a middle nature, then malt-dust will not be amiss. All these manures are easily procured, and therefore we have mentioned none that are scarce and dear: but as variations of soil are infinite, and few people know the true nature of any field (especially if it be of the mixed kind), we recommend the compost dung-hill, as the surest and most universal assistant upon such occasions.

Many other manures may be good for lucern, but dung probably is not one of the best, except it be very old, and well corrected with proper mixtures of a sweet, as well as fertilizing nature, sufficiently warm and cherishing, but no ways rank; for dung (especially if it be new) produces in general very luxuriant, troublesome weeds, insects in abundance of various kinds, and gives the grass a foul, cloying, putrid taste.

The owner's eye, it is true, may be deceived, and his hopes encouraged by the largeness of the crop; but the sagacious four-footed animals will distinguish better than we can pretend to distinguish; and if they could present a petition to their masters, as the white heifers are reported once to have done to the emperor Julian, they would remonstrate not a little against the immoderate use of this manure. Nevertheless, assertions like the present ought to be confirmed by some proof: an experiment therefore was made upon four acres of grass ground, of which one half was dressed with stable dung, and the other with wood ashes kept dry. The former moiety appeared the most rich and luxuriant of the two, but the cattle always neglected it, till they had bitten the latter down to the bare earth.

Having thus given the result of my experience in regard to dung as a manure for lucern, I shall subjoin only one short caution, which is, that no dung, not even of the best kinds, must be spread on a lucern plantation, till it be two years old at least.

In all grounds inclinable to moisture, and such particularly as are of a clayey cast, it is pretty certain, that the preference ought to be given to foot-dressing, and, after foot, to chimney-ashes (those of green wood especially) provided they are housed and secured from wet; then soap-boiler's ashes may take place, coal-ashes well sifted, charcoal-ashes, and malt-dust; nor might the ashes of lime be amiss, nor lime itself, when mixed with such fine mould as may be found under a short sweet turf, in lanes or commons. The compost-dunghill also, as observed before, should be applied to, which, at the end of twelve months, having been thrice turned, will spread almost as well as ashes or foot: nor will such compost want strength when it is rightly managed: for if the dunghill be moistened at times with the brine, soap-suds, dish-washings, and chamber-lice, &c. of the family, then, when it is removed into the fields, the sharp, pungent, strong salts, which fly off, will make the labourers sneeze, and occasion a smarting in their eyes.

When you manure lucern with foot, dry chimney-ashes, lime, soap-boiler's ashes, &c. it is sufficient to dress the rows only, because these finer sorts of manure may be dispersed in the nicest, exactest quantities, if sown in the Berkshire manner, with a peat-ash spoon; but if coarser manures are to be employed in larger quantities, as old dung, marle, compost-dressings, &c. I would then advise the proprietor of the field to manure the intervals and rows promiscuously.

Nothing can be more cheaply and easily managed than manuring lucern with foot-dressings; for the labourer, if he makes use of a peat-ash spoon and seed-lip, may sprinkle the rows of an acre in four or five hours, walking down the first interval, and returning by the second, and so progressively.

Ashes may be sown in the same manner.

It may not be amiss to answer a couple of questions which have been often proposed.

The first question is, how, and in what manner (by way of result from the considerable number of experiments made by me) I would advise any gentleman to prepare three or four acres of land for receiving lucern? this being an undertaking of some moment.

The second question is, how to perform this work in the shortest, safest, and most economical manner? Concerning both which points my ideas are as follow, this only premised, that I am here endeavouring to make the expence of the undertaking as cheap as possible; otherwise, where people pay no regard to a few incidental charges, I would recommend Mr. Boyle's method of preparing a field for receiving transplanted lucern, who began his experiments of lucern in the same year that I did, but proceeded upon a larger scale; for he undertook the culture of six acres at once.

His preparation of the field was as follows:

In the year 1757, he gave his field a summer fallow, and having thoroughly ploughed and harrowed it (not as farmers understand these words, but effectually, instead of superficially) he sowed wheat after the ground had been dressed with lime. In 1758, his crop of wheat was very great. Immediately after harvest, he gave the land in question a severe discipline, using every method for pulverising the earth, and extirpating weeds, that the best husbandmen are acquainted with, either in our kingdom or abroad; so that the field appeared again a perfect fallow. Then ploughing it very narrow and sharp, he made water thorough with the plough, and left it in this condition for the winter 1758.

In spring 1759, he made many French drains in the field, as before they had made open ones for the winter: and, by stone-picking the land, had nearly stones sufficient to fill them. In March, the same year (taking advantage of the first fine weather) he slit the ridges with the plough, and reduced the land to the finest tilth he was able, and transplanted the lucern from his nursery in autumn; in the whole process of which he followed Duhamel exactly.

Nothing in husbandry could be more sensible and masterly, than this preparation of a large piece of the land for receiving lucern.

In the present case it may suffice to say, that supposing the nursery to be properly prepared, and the seeds sown in the first week of April, before the season for transplanting, according to directions already given; I would recommend a field in good tilth, after barley harvest, and before oats have been sown in it. This field should be thoroughly ploughed and harrowed twice, which we will suppose to be, for example, in autumn of the present year, 1764. After each ploughing and harrowing, there should be a very diligent burn-beating. But if the season should prove too wet at the time of a second burn-beating, we make a virtue of necessity, and the weeds and trumpery must be raked together and carried off.

Then give the field a trench-fallow ploughing for winter, and early in March, 1765 (if the weather any ways permits), having manured your ground as the relative nature of the soil requires, and ploughed and harrowed it again to an exquisite fineness, drill in a crop of field-pease, as early in the spring as is convenient with prudence and safety; for this crop must be ripe, and removed, by the last day of July. Much depends upon this point of foresight: however, the pease, by standing thinner than in hand-sown promiscuous crops, being at the same time banked and hoed with greater ease, and enjoying more room, free air, and sun-shine, will, in all probability, gain an advance of ten days at least in their ripening. This will be a great point secured; for it is in husbandry as in war; there are critical moments, which never present themselves a second time in the same campaign.

This pea-crop being hacked, and moved from the field by the fourth or fifth of August, call in all the assistance you have of husbandry-strength, or can procure, and plough and harrow the field, and burn the pea-roots, weeds, &c. as often as you have time, before the twentieth of August: and then (your nursery being supposed to be in perfect readiness) transplant your roots as before directed, and contrive to close your work by the end of the month.

Mr. Lullin de Chateauvieux has obliged the world with many

many valuable experiments, on the culture of lucern, which must not be omitted here : but it may not be amiss to give first Mr. Miller's directions for cultivating lucern, as it has been often mentioned in the article. They are as follows :

"After having well ploughed and harrowed the land very fine, you should make a drill quite across the ground, almost an inch deep, into which the seeds should be scattered very thin : then cover them over a quarter of an inch thick, or somewhat more, with the earth : then proceed to make another drill, about a foot and a half from the former, sowing the seeds therein in the same manner as before, and so proceed through the whole spot of ground, allowing the same distance between row and row, and scatter the seeds very thin in the drills. In this manner an acre of land will require about six pounds of seed ; for when it is sown thicker, if the seeds grow well, the plants will be so close as to spoil each other in a year or two, the heads of them growing to a considerable size, as will also the roots, provided they have room. I have measured the crown of one root, which was in my possession, eighteen inches diameter, from which I cut near four hundred shoots at one time, which is an extraordinary increase, and this upon a poor dry gravelly soil, which had not been dunged for many years, but the root was at least ten years old ; so that if this crop be well cultivated, it will continue many years, and be equally good as when it was first sown : for the roots generally run down very deep in the ground, provided the soil be dry ; and although they should meet a hard gravel a foot below the surface, yet their roots would penetrate it, and make their way downwards, as I have experienced, having taken up some of them, which were above a yard in length, and had run two feet into a rock of gravel, so hard as not to be loosened without mattocks and crows of iron, and that with much difficulty.

"The reason for directing this seed to be sown in rows is, that the plants may have room to grow ; and for the better stirring the ground between them, to destroy the weeds, and encourage the growth of the plants, which may be very easily effected with a Dutch hoe, just after the cutting the crop each time, which will cause the plants to shoot again in a very little time, and be much stronger than in such places where the ground cannot be stirred : but when the plants first come up, the ground between should be hoed with a common hoe ; and if, in doing of this, you cut up the plants where they are too thick, it will cause the remaining to be much stronger. This hoeing should be repeated two or three times while the plants are young, according as the weeds are produced, observing always to do it in dry weather, that the weeds may the better be destroyed ; for if it be done in moist weather, they will root and grow again.

With this management, the plants will grow to the height of two feet or more, by the beginning of August, when the flowers will begin to appear, at which time the lucern should be cut, observing to do it in a dry season, if it is to be made hay, and keep it often turned, that it may soon dry, and be carried off the ground ; for if it lie long upon the roots, it will prevent their shooting again. After the crop is taken off, you should stir the ground between the rows with a hoe, to kill the weeds, and loosen the surface, which will cause the plants to shoot out again in a short time ; so that by the beginning of September there will be shoots four or five inches high, when you may turn in sheep upon it to feed it down : nor should the shoots be suffered to remain upon the plants, which would decay when the frosty weather comes on, and fall down upon the crown of the roots, and prevent their shooting early in the succeeding spring.

"The best way therefore is to seed it until November, when it will have done shooting for that season : but it should not be fed by large cattle the first year, because the roots being young, would be in danger of being destroyed, either by their trampling upon them, or their pulling them out of the ground : but sheep will be of service to the roots by dunging the ground, provided they do not eat it too close, so as to endanger the crown of the roots.

"In the beginning of February, the ground between the rows should be again stirred with the hoe, to encourage them to shoot again : but in doing of this you should be careful not to injure the crown of the roots, upon which the buds are at that time very turgid, and ready to push. With this management, if the soil be warm, by the middle

of March the shoots will be five or six inches high, when if you are in want of fodder, you may feed it down till a week in April ; after which it should be suffered to grow for a crop which will be fit to cut the beginning of June, when you should observe to get it off the ground as soon as possible, and stir the ground again with the Dutch hoe, which will forward the plants shooting again, so that by the middle or latter end of July, there will be another crop fit to cut, which must be managed as before ; after which it should be fed down again in autumn : and as the roots by this time will have taken deep hold in the ground, there will be little danger of hurting them, if you should turn in larger cattle ; but you must always observe not to suffer them to remain after the roots have done shooting, lest they should eat down the crown of the roots below the bud, which would considerably damage, if not destroy them.

"In this manner you may continue constantly to have two crops to cut, and two feedings upon this plant, and in good seasons there may be three crops cut, and two feedings, which will be a great improvement, especially as this plant will grow upon dry, barren soils, where grass will come to little, and be of great use in dry summers, when grass is often burnt up : and as it is an early plant in the spring, so it will be of great service when fodder falls short at that season, when it will be fit to feed at least a month before grass or clover ; for I have had this plant eight inches high by the tenth of March, old style, at which time the grass in the same place has scarcely been one inch high.

"That cold will not injure this plant, I am fully satisfied ; for in the very cold winter, anno 1738-9, I had some roots of this plant which were dug up in October, and laid upon the ground in the open air till the beginning of March, when I planted them again, and they shot out very vigorously soon after : nay, even while they lay upon the ground they struck out fibres from under the side of the roots, and had begun to shoot green from the crown of the roots. But that wet will destroy the roots, I am fully convinced ; for I sowed a little of the seed upon a moist spot of ground for a trial, which came up very well, and flourished exceedingly during the summer season, but in winter, when the great rains fell, the roots began to rot at bottom, and before the spring most of them were destroyed.

"The best places to procure the seed from, are Switzerland and the northern parts of France, which succeeds better with us than that which comes from a more southern climate : but this seed may be saved in England in great plenty ; in order to which, a small quantity of the plants should be suffered to grow uncut till the seeds are ripe, when it must be cut, and laid to dry in an open barn, where the air may freely pass through : but the seed must be defended from the wet ; for if it be exposed thereto, it will shoot while it remains in the pod, whereby it will be spoiled. When it is quite dry, it must be threshed out, and cleansed from the husk, and preserved in a dry place till the season for sowing it : and this seed saved in England is much preferable to any brought from abroad, as I have several times experienced ; the plants produced from the French, Helvetian, and Turkey seeds, which were sown at the same time, and on the same soil and situation.

"I am inclinable to think that the reason of this plant's not succeeding, when it has been sown in England, has either been occasioned by sowing it with corn, with which it will by no means thrive (for though the plant be very hardy when grown pretty large, yet at its first coming up, if it be incommoded by any other plant or weed it seldom does well ; therefore it should always be sown by itself, and carefully cleared from weeds until it has strength, after which it is not easily destroyed) ; or, perhaps, people have sown it at a wrong season, or in wet weather, whereby the seeds have rotted, and never come up, which hath discouraged their attempting it again : but however the success has been, I dare aver, that if the method of sowing or managing this plant, which is here laid down, be duly followed, it will be found to thrive as well as any other sort of fodder now cultivated in England, and will continue much longer : for if the ground be duly stirred after the cutting of each crop, and the first crop fed, as hath been directed, the plants will continue in vigour twenty years, or more, without renewing, provided they are not permitted to seed, which would weaken the roots more than four times cutting would do.

"The hay of this plant should be kept in close barns, it being too tender to be kept in ricks open to the air as

other hay : but it will remain good, if well dried before it be carried in; three years. The people abroad reckon an acre of this fodder sufficient to keep three horses all the year round : and I have been assured by persons of undoubted credit, who have cultivated this plant in England, that three acres of it have fed ten cart-horses from the end of April to the beginning of October, without any other food, though they have been constantly worked. Indeed the best use that can be made of this grass, is to cut it and give it green to the cattle. Where this hath been daily practised, I have observed that by the time the field has been cut over, that part which was first cut, hath been ready to cut again; so that there has been a constant supply in the same field from the middle of April to the end of October, when the season has continued long mild; and when the summers have proved showery, I have known six crops cut in one season: but in the dry seasons there will be always three. When the plant begins to flower it should then be cut: for if it stands longer the stalks will grow hard, and the under leaves will decay, then the cattle will not so readily eat it. Where there is a quantity of this cultivated, some of it should be cut before the flowers appear, otherwise there will be too much to cut within a proper time.

"When this is made into hay, it will require a great deal of making: for as the stalks are very succulent, it must be often turned, and exposed a fortnight before it be fit to house; for this requires a longer time to make than sainfoin: therefore, when it is cut, it should be carried to make upon some grass-ground; because the earth in the intervals of the rows will wash up, and mix with the hay in every shower of rain; and, by carrying it off as soon as it is cut, the plants will shoot out again soon: but it is not so profitable for hay, as to cut green for all sorts of cattle, but especially horses, which are extremely fond of it; and to them it will answer the purpose of both hay and corn, and they may be worked at the same time just as much as when they are fed with corn, or dry food." *Miller's Gard. Dict.*

Experiments on Lucern cultivated according to the New Husbandry, by M. de Chateauvieux.

"It is truly with regret, says M. de Chateauvieux, that I am forced to treat a subject of this importance, in so summary a way as the limits of this letter require. However, I hope that even this general account of my experiments may be a guide to those who would cultivate this plant. Many persons who live at a considerable distance from this place (Geneva) have already followed my example, and are extremely well satisfied with their success.

"Though I agree with M. Duhamel, and the other partisans of the New Husbandry, that lucern and sainfoin thrive best when cultivated in beds; yet my practice differs, in many respects, from theirs. This difference consists in,

1. The Principle which I apply particularly to the Culture of Lucern.

"Lucern grows naturally with one large perpendicular, or tap-root, which penetrates very deep into the earth, and has few, if any, lateral roots. From similar experiments on other tap-rooted plants, I was induced to think, that this too, by transplanting it, and at the same time cutting off part of its tap-root, might be made to shoot out several horizontal roots, which, reaching into the loose mould of the alleys, and extending themselves there, would collect a greater quantity of nourishment for the plant, and consequently enable it to produce more abundant crops.

"The event has proved, that when we reason on sound principles, we seldom err. My transplanted lucern pushed out numbers of large lateral roots, and these branched out again into others, which may be multiplied without end by frequent culture of the alleys: for the horse-hoe has the same effect on these horizontal roots as cutting has upon the tap-root.

2. The Method of transplanting the Lucern.

"I made several beds, some about three feet wide, (including the alleys) into which I transplanted a single row of lucern; others about three feet nine inches, into which I transplanted two rows; and others about four feet three inches wide, in which I put three rows. The design of this variation was, to see by which of these three methods the same extent of ground would produce the greatest quantity

of lucern: I believe it will require five or six years to determine exactly which of them will be best; because, as the plants increase every year in bulk, their produce alters, and may perhaps not keep in proportion to their first years, though probably the difference would not be great. But without waiting so long, I can already see, that the crop will be greatest by planting only one row on each bed.

"The plants in the single rows were six inches asunder, nor should they ever be nearer; and those in the double and triple rows, were eight or nine inches distant from each other. I must observe, that I likewise sowed lucern with the drill, in beds, in which it has remained without transplanting. It is very fine: but not near so strong and flourishing as that which I transplanted. When lucern is sown where it is to remain, it necessarily requires being thinned, and that operation takes up more time than transplanting it would do."

Rules to be observed in transplanting Lucern into Beds.

"1. The middle of the beds must be raised and arched as high as possible; and as the lucern is to remain several years on the same ground, no pains should be spared to prepare the earth as well as can be.

"2. Lucern should be sown in the spring, and in a rich mould, that the plants may be strong enough to transplant in September.

"3. Plants two or three years old may be transplanted as well as younger ones.

"4. They should be transplanted in September, that they may have time to take fresh root before the winter comes on.

"5. If they cannot conveniently be transplanted in September, it may be done in October, provided the weather be not frosty.

"6. The mould into which they are transplanted should be moist; and if the weather be somewhat rainy, it is so much the better. In this case, I have never found it necessary to water the plants.

"7. If lucern is transplanted in November or December, there is danger of the frosts forcing many of the plants out of the ground.

"8. If too warm and dry a season prevents transplanting in September or October, it is best to stay till the winter is past. The plants will then be sure of taking root, and very few of them will fail.

"9. If they can be transplanted in autumn they will yield pretty good crops the next year: but if they are not transplanted till spring, the next year's crop will be but indifferent.

"10. The plants must be taken out of the nursery, with great care and patience, that their roots may not be damaged.

"11. The roots should be left about six or seven inches long, and the green tops should be cut off within about two inches of the crown of the root.

"12. The plants will take root the sooner, if they are put into water as soon as they are taken up, and kept in it till they are planted.

"13. They are planted in holes made with a planting stick in the same manner as cabbages or lettuces are planted in a garden.

"14. The best way of planting lucern is, to cut a straight channel two or three inches deep and set the plants at the bottom of it, covering them up to the neck.

"15. Great care should be taken not to suffer any weeds to grow among the lucern; at least for the two or three first years. To this end, the rows should be weeded by hand, as well as the edge of the alleys near the plants, where the horse-hoe cannot go.

"16. The alleys may be stirred, either with the single cultivator, or the cultivator with two mould-boards; which at the same time that it destroys the weeds, keeps the mould loose.

"17. The first stirring may be given with the cultivator with which a furrow may be cut on each side of the main furrow in middle of the alleys, by which means the earth will be turned over on both sides of it.

"18. The second stirring may be given by the cultivator with two mould-boards, by drawing it along the middle of the alleys. This will turn the earth towards the rows. By these alternate stirrings, the alley will be constantly kept in a loose state.

"19. This culture is so easily performed, and in so short a time, that it may be repeated frequently. In this I dif-

I differ from M. Duhamel, who orders it but seldom. My opinion is, that the alley should be stirred once a month, during the whole time that the lucern is in a growing state.

" 20. If the alleys be kept from weeds, less stirring them may do: but the mould should never be suffered to grow too hard.

" 21. As soon as some of the plants begin to blossom, the lucern should be cut. It will then make excellent fodder, superior to every other kind.

" 22. The lucern hay should be dried as quick as possible, and frequently turned. The less it is exposed to the heat of the sun the better fodder it makes.

" 23. Lucern must not be housed till it is dry: but at the same time care must be taken that it be not too dry: for then many of the leaves will fall off, as they dry sooner than the stalks.

" 24. Cattle must not have too much lucern given them at a time, till they are accustomed to it.

" 25. No cattle should ever be suffered to feed on the beds of lucern. If the earth is very dry, towards the latter end of autumn, sheep will do it the least hurt. If the plants are then tall enough to be moved, the best way is to cut them, and give them green to the cattle.

" These rules contain all that is essentially necessary for making and keeping in good order this kind of artificial pasture. I can safely say, that whoever tries them, will be abundantly rewarded for his trouble and expence. Saint-foin may be cultivated in the same manner."

Account of the Produce of Lucern planted in Beds, and cultivated according to the Principles of the New Husbandry: with some important Reflections on the Advantages which may be obtained therefrom: by M. de Chateaufvieux.

" No judgment should be formed of what lucern may produce, by the crops of the first or second year: it is then too young to be able to yield much. If we were to calculate even by its third year's produce, we should still consider, that as the plants increase every year in bulk and vigour (and where they will stop I am not yet able to determine) the produce will be proportioned to that increase, and consequently the crop of each succeeding year will be greater than that of the former.

" The crops I am going to speak of, are those of the second and third year: but my calculations will be made on that of the third year. It is proper to remember, that the year 1753 and 1754, were uncommonly dry, inasmuch that sometimes, not a drop of rain, nor scarce any dew fell between the cutting of one crop and that of another. The seasons were so unfavourable to the production of grass, that hay rose to an excessive price.

" I shall first say what was the state of the plants of lucern in the third year, and afterwards how much hay they yielded.

State of the Plants in their third Year.

" As the part of the plant which I now consider is that which is buried in the earth, I uncovered numbers of them, that I might be able to judge of their general state. I was greatly struck with the effect which transplanting had had upon them. Instead of one perpendicular root, which they usually have, all these plants had three, four, five, and sometimes more, almost equally big roots. They were, in general, three quarters of an inch in diameter, and proceeded from the original root, which was now at least an inch in diameter, and in many of the plants an inch and a half. After the most careful search that I could possibly make, I could not find one plant of lucern sown in the common way, though it had stood twelve, twenty, or more years, whose tap-root had grown to the bigness of an inch diameter: few of them were above half, or at most three quarters of an inch thick. This difference is very great.

" I likewise found, that the roots of the transplanted lucern had produced another kind of roots, of which I saw none about those of the old lucern. These were a great number of fibrous roots, some of which were already one twelfth of an inch in diameter, and looked as if they would also become principal roots.

" The stalks seem to rise out of the earth; and from the first time of cutting them, a kind of head forms just above ground, which extends itself every year. The first year, this head was two or three inches wide: the second

year it was generally about six inches over, and this third year, almost half the plants have a crown ten or twelve inches in diameter: and as many of them have grown so as to touch one another, their crowns are become of an oval form, having extended themselves on the sides, where they met with no resistance.

C R O P S.

" I have a field of lucern in beds, divided into two parts. This is the third crop of lucern off one of them. The beds are 250 feet long. In 1753, I cut this lucern six times; viz. in May, June, July, August, September, and the beginning of November. This last cutting was not near so plentiful as the others, and I dried it within doors:

" These cuttings off one bed, on which there was but one row of lucern, yielded 140 pounds of well dried hay.

" In 1754, the lucern was late before it began to shoot, and the earth was drier than the year before. I had but five crops: the first was cut on the 27th of May; the second on the 1st of July; the third on the 27th of July; the fourth on the 26th of August; and the fifth on the 23d of October. These five cuttings yielded in all 225 pounds of well dried hay off each bed.

" A field 250 feet long, which was the length of my beds, and 210 feet wide, contains an arpent of our measure. This arpent, divided into sixty-eight beds, each three feet wide, producing after the rate of 225 pounds of hay off each bed, would yield in all 15300 pounds; which is infinitely more than is ever obtained in the common way.

" The beds with three rows yielded much less. The third year, their crops amounted to no more than 169 pounds off each bed, which is a fourth less than the others: and as these beds are wider, instead of having sixty-eight, as in the former disposition of the arpent, there will be only forty-seven, each four feet three inches wide, the total produce of which will be but 7943 pounds: consequently this arpent will yield little more than half as much as an arpent laid out in beds three feet wide, planted with only single rows."

Remarks by M. de Chateaufvieux.

" The plants of lucern had the fate of all kinds of plantations: that is to say, some of them were more vigorous than others. The greatest number of the plants produced each of them a pound of dry hay, and some of them yielded two pounds. I look upon these last as such extraordinary productions, that I do not expect many of them to yield the like quantity again. I think one may be very well satisfied, if the plants, one with another, yield a pound of hay a-piece every year. This is nearly the result of my experiment on beds which had but one row; and the produce of these would have been still greater, if many of my plants had not failed: in the room of which I set young ones, which could not acquire sufficient strength to yield full crops.

" In these experiments, I have employed no dung: neither have I for any of my corn fields. I have reserved it for improving my pastures and meadows; and intend next to apply it to my lucern, which, I doubt not, but will be much the finer for it. The only thing now remaining is, to know by experience which will be the best way of using it. I have some thoughts on that head, which may render it much more profitable.

" Lucern deserves to be cultivated with care: not only on account of the great quantity of fodder which it yields, but likewise because the quality of its hay is superior to any other. The New Husbandry will render it still more perfect. Plants cultivated this way enjoy the benefit of a free circulation of the air, and that circulation keeps them sweet and sound, and free from all mustiness towards their roots: for, being open to the rays of the sun, that great source of kindly vegetation, they attain great perfection in all their parts, both as to their substance, and their flavour. Cattle eat this food greedily, and are better nourished with it, than with any other: but as every excess is bad, too great a quantity should not be given them at once, especially at first, lest it should swell them. The best way is to bring them to it by degrees.

" I have experienced these qualities in this hay, by comparing

paring it with every other sort. The excellence of this, justifies the principles on which the New-Husbandry is founded, I have offered to my horses bundles of every kind of hay, and at the same time a bundle of this hay of lucern. They have not hesitated a moment to prefer the latter. Nothing but its superior qualities could determine them in this choice, which never varied, and has always been in favour of the lucern cultivated in this manner.

"It would be lavishing this excellent fodder, to feed horses entirely with it. It need only be given them by turns with common hay : which will be a great saving : for this lucern will supply the place of oats. I am certain that my horses fed partly with this hay, and without oats, will be in better plight, stronger, and more vigorous, than those which are fed with meadow hay and corn in the usual way. It is now some time since I have fed my coach-horses with it, and have retrenched their oats. Instead of this last food, and at the hours they used to have it, I give them lucern chopt, as the Spaniards do straw to their horses. Mine are fond of it, and shew the same impatience to find it in their manger, as if it was oats ; and since their being put under this diet, they are in better condition than before, and so mettlesome, that the coachman has enough to do to keep them in.

"When I said that retrenching the oats would be a considerable saving, I did not so much mean the saving of the expence of that corn, as the better improving of many vast tracts of land which are sown with oats, and might with proper management produce much more useful and more profitable sorts of grain, notwithstanding the too general prejudice, that some lands are not capable of bearing any better. For my part, I am thoroughly satisfied, that whatever ground can bear a crop of oats, can likewise, under the New Husbandry, bear any other grain."

Continuation of M. de Chateauvieux's Account of his Experiments on Lucern, in the Years 1755 and 1756.

"The great drought of the year 1755, was accompanied with great heat ; and the year 1756 was very rainy, and moderately warm, there being but very few hot days in it.

"My lucern was exposed to a most severe winter in 1755, when the frost was excessive hard, and lasted very long. M. de Reaumur's thermometer was some days, at different times, eight, nine, ten, twelve, and thirteen degrees below the freezing point ; and on the third of February a thermometer in the open air stood at sixteen degrees below freezing. These severe frosts made me uneasy for my lucern, which, however, bore them without receiving any damage.

"The rains in 1756 did no hurt to these plants, but they prevented my cutting them at proper times. I had but four crops of lucern this year, being obliged to wait for an appearance of fine weather to dry it in, before I could venture to cut it down. These rains likewise hindered my giving the proper hoeings to the alleys, which were full of weeds during the summer and autumn. I chose rather to leave them in that condition, than attempt to hoe them while the ground was over wet, not doubting but the spring hoeings would easily destroy them.

"In 1755, I cut my lucern five times : the first was, on the third of May, before any flowers appeared : the second on the twelfth of June : the third, on the fifteenth of July : the fourth on the twenty-first of August : and the fifth, on the seventh of October. I was obliged to finish the drying of this last cutting in barns, and under cover.

"In 1756, which was the fifth year of these plants, I cut them but four times : the first, on the third of June : the second, on the first of July : the third on the fourth of August : and the fourth on the twenty-seventh of September.

A bed 250 feet long, with only one row of lucern,

Yielded	{	In 1754	-	-	-	-	225	} pounds of dry hay.
		1755	-	-	-	-	197	
		1756	-	-	-	-	281	

In three years, 703 pounds.

A bed of the same length, with three rows of lucern,

Yielded	{	In 1754	-	-	-	-	169	} pounds of dry hay.
		1755	-	-	-	-	180	
		1756	-	-	-	-	226	

In three years, 575 pounds.

Observations by M. de Chateauvieux.

"We see, by the above account of three years, that a piece of ground laid out in narrow beds, planted with only one row of lucern, yielded a greater produce than the same extent made into wider beds, and planted with three rows.

"I shall not, however, pretend to determine from this one experiment, that it is best to lay down large fields in this manner. I think it will be right to try first, whether the success will be the same on different soils, and likewise on lands whose exposition may be more or less advantageous. If after repeated trials, the beds which have but one row of plants, yield the greatest quantity of hay, that method certainly is to be preferred. To clear up this point still more to my satisfaction, I continue to plant lucern in beds, some with one and others with three rows.

"The difference between the crop of 1756, and those of the two preceding years, would induce me to think that rainy seasons are best for the production of hay : but still, the greater quantity which the year 1756 produced, must not be imputed to the rain only : we should likewise consider that the plants had thrived greatly since 1754 ; that their stems were grown much larger, and their roots much stronger and more numerous, and that they were consequently able to yield much greater crops than before. They have abundantly answered my expectation, both as to quantity and quality.

"With respect to the quantity, it is much greater than that of any common fodder : I mean, of any that the same extent of ground would have produced, if cultivated in the common way, though it would then have been covered with an immense quantity of plants. This is a fact, which numbers of experiments prove, and which we shall cease to wonder at when we consider the great effects of the frequent stirring of the alleys. To this it is that I owe the repetition of my crops and their being all of nearly equal goodness. I do not exaggerate when I say that every summer month, which is the time I generally allow between each cutting, will produce shoots two feet long, and sometimes more : and supposing that I cut them but five times a year, each plant will have produced after the rate of nine or ten feet length of shoots, and that in the same time that most meadows will not produce grass above two feet long.

"As to the quality of this hay, I continue to prefer it to all other fodder. My experience has confirmed what I said of it in 1754 ; and I shall only add, that I have since found, that it is as good at the end of four years, as when it is first cut. If there was any difference, horses would soon be sensible of it : but they eat of either without distinction.

"I feed my horses with it, chiefly in the summer, at which time they do most work, and am more and more sensible of the advantages of it. Five or six pounds of lucern a day, are sufficient for a middle-sized horse : but the quantity may be increased or diminished, according as the horse is nourished by it : for in that there is great difference." *Culture des Terres, tom. IV. c. iii. art. 15.*

The following account of the cultivation of lucern, was communicated to the public by a very ingenious husbandman, and merits the attention of the reader.

Having read and heard a great deal of lucern, I determined to have some of it myself ; and Mr. Miller's method seeming to me by far the most rational, I resolved to follow it : accordingly, the 17th of July, 1763, I ordered a field of three acres and a half, then under rye-grass and clover, to be ploughed deep, and sown with turneps. The crop was middling : I sold them to a cow-farmer for nine guineas : he drew and carted them home. If I had had sheep, I would have fed them on the field.

By the twenty-seventh of March, 1764, the field had been twice ploughed, the first time ten, and the last time near twelve inches deep, with the Rotherham-plough and four horses a-breast : the soil is light and stony, with a rock of gravel about ten or twelve inches deep, and had never before been ploughed above six or seven inches deep ; however, I knew it was right to go as deep as I could for a tap-rooted plant, as the lucern is.

I was greatly pleased with reading M. Lullin de Chateauvieux's account of his method of transplanting lucern, and determined to follow it, from a full conviction that it must be superior to every other method.

Accordingly I ordered the field to be sown with Poland oats, and laid out about twenty-eight rods in beds four feet wide, alleys one foot and a half, which were sown with lucern in broad-cast by my gardener, in the same manner

manner as you sow cabbages or favoys in feed-beds : one bed, however, out of curiosity, I ordered him to sow in the following manner :

Run a garden-line through the middle of the bed from one end to the other ; draw a small drill along the line, about half an inch deep ; then move the line six inches, and make another drill, and so on : by this means you will have nine drills on a bed four feet wide. When this is done, fill a quart or a pint bottle near full with your lucern-feed, cork the bottle, bore a hole in the cork, and insert a quill cut at each end : this will be found a great assistance in sowing the seed thin and regularly in the drills : and I must observe, that the bed which I sowed in this manner afforded me the greatest quantity of plants, and by far the finest. Another advantage attending it is, that it is kept clean with much more ease, and far less expence ; for a gardener, with the small three-inch hand-hoe, will clean a great deal of ground in a small space of time. When the bed is sown, the seed must be covered with care : rather chuse the backside of a small rake than the teeth.

By the middle of August, my plants looked very well, and were mostly in bloom, when I ordered them to be mown, and given to my horses and cows, who seemed as if they had a high treat.

The oats being got in, I ordered the field to be deep ploughed again, and then waited for a season of rain to begin my planting, which, by my journal, did not come till the fifteenth and sixteenth of September ; and the field being first well harrowed, we went to work the seventeenth, and continued planting till the twenty-ninth ; nor can I now see any difference between those planted the seventeenth or twenty-ninth. Though I quite agree with the author of the Essays, that it is best to plant sooner than I did, if possible ; yet I must observe, that what may do for gardens, or small pieces of ground, will not do for fields. From the last week of August to the middle of September, seems to me a very proper time. But "filling each hole with water, making drills, half-filling them with sea-sand or wood ashes, and watering each plant," as the author of the Essays mentions, is an endless and very expensive work.

For my part, I kept my eye on M. Chateauvieux's directions, as laid down above, with regard to that part that relates to planting ; but another ingenious gentleman, having cautioned the public against planting on ridges, I must needs say, I was fearful of the rain and frosts myself, if planted in that manner, especially on light land ; and therefore I ordered my field to be ploughed as level as possible, and made my man, after the field was ploughed, go three bouts on each side the furrow, so that, when harrowed across, you could hardly tell where they were. The field being brought to this order, as I said before, we began to plant the 17th of September : two men with spades dug up the plants, and two women cut them : some care is certainly required in taking them up, but I did not find it great ; it was done by common labourers. The women were ordered to cut the plants to about six or seven inches long in the root, and the tops to about two inches, as M. Chateauvieux directs. They did it very handily : their method was to take them up one by one, (so that they could throw by the faulty ones) and when they had about a dozen in their hands, they cut them at top and bottom with one stroke of the knife at each end. Each had a washing-tub by her side, filled to about six inches with water : as they cut the plants, they set them in the tubs ; and as they filled one tub, another was brought them.

The method of planting is the same as for cabbages : men who are used to work in gardens will do it very handily with a dibble or planting stick ; but that mine might stand with all possible exactness, each man had a garden line and reel : and as I think I shall be very able to keep them clean with M. Lullin's single cultivator, the rows are only twenty inches apart, and six inches in the lines.

If I find a difficulty in keeping them clean in this method, then by drawing every other row, which may be done with great ease, my plants will stand at the distance directed by M. Chateauvieux, of three feet four inches.

I was very impatient to see the effect transplanting would have, and therefore, as soon as my plants in the seed-bed were about six inches high, I drew several, cut and transplanted them, and in the autumn I took up these plants, and found they had all formed new tap-roots round the bottom of the piece (if I may so call it) planted, and

instead of one, they had from five to thirteen new roots : this, you may suppose, gave me great pleasure, and convinced me, that the illustrious Swiss was quite right.

The author of the Essays on Husbandry, I find, cut his plants with scissars ; this must be very tedious work ; and, with submission, I think he is quite wrong in cutting his plants to the length of nine or ten inches. Six or seven inches seem to be a more proper length ; for the ground being dug or ploughed about twelve inches, the new roots will have five or six inches of well-loosened mould to strike into, which must be a great advantage to the plants ; and if gravel, or a strong clay, is near the surface, I am convinced, mine, or rather M. Lullin's, is the best method.

Yet this gentleman says, he cut his tap-roots too short, and knew not how to manage a root that was very small : in regard to the last, I must observe, that, if they were very small, I ordered them to be thrown away. So much has been said on the necessity of keeping lucern in broadcast, drills, or transplanted, free from weeds, that I will say nothing on that subject.

At the same time that this gentleman so warmly recommends M. Chateauvieux's method of cultivating lucern by transplanting, he has, I fear, thrown a stumbling-block in the way of most gentlemen, and, I think, every farmer ; I mean his calculation of the expence ; this, therefore, I must endeavour to remove.

When I began to cultivate lucern in this manner, the only defect I could find in M. Chateauvieux's account was that he had not told the public how much ground they were to set apart for a nursery : this deficiency, however, I can supply to those who come after me, for sixteen rods will be about the quantity for an acre ; and then, I think, the expence of transplanting will stand as follows :

	l.	s.	d.
Digging, spit-deep, sixteen rods, at three-pence per rod	0	4	0
Seed, three pounds, at one shilling per pound	0	3	0
Weeding the nursery twice with the three-inch hand-hoe. (By sowing in this manner, transplanting will not be wanted ; nor do I think it proper, as they are to be transplanted again)	0	3	0
Ploughing	0	10	0
Transplanting	1	5	0
Hand-hoeing the plantation once, the middle or latter end of October, in dry weather, which men used to hoeing turnips, will do for three or four, but say	0	5	0
	2	10	0

This, I am persuaded, is the full expence of making the plantation ; yet the author of the Essays has strangely worked it up to six pounds twelve shillings per acre : however, I readily submit this account to the inspection of every farmer and every gentleman in this kingdom, conversant in matters of this kind.

If the spring-ploughing for barley or oats has been nine or ten inches deep, then a ploughing in autumn of twelve inches will be sufficient, and cannot be charged at more than ten shillings. The trenching for the seed-beds may be done at leisure time ; so may the weeding of the nursery, and the hand-hoeing of the plantation : then the real expence to the farmer will only be the seed and transplanting, or one pound eight shillings per acre.

As to what this gentleman calls the yearly charges, I can by no means agree to them : for the plantation having been weeded in October, will lie very safe and well till the latter end of February or beginning of March : then in dry weather, it may be hand-hoed again, the expence of which has before been charged at five shillings per acre ; to which add four horse-hoeings after each cutting, at eleven shillings, which makes sixteen shillings per acre the annual charge.

I cannot recollect any thing further that is necessary to be said on the subject of transplanted lucern ; but as I would have every one, who writes to you on subjects of this sort, tell the truth, the whole truth, and nothing but the truth, so I think it but just to say a word or two on lucern sown in broadcast, or Mr. Rocque's manner. I live within a few miles of Mr. Rocque ; and must add, that I have paid great attention to the culture and growth of lucern and burnet for some years past : so that I think I am pretty well acquainted with them.

The author of the Essays says, "If lucern is sown in broad-cast with corn, no care can keep it clean: it may last two years, only one crop being tolerable, and then must perish in the common course of nature." And several of your correspondents are also of opinion it will never succeed in this method; but I know it will; for I have seen it cut three or four times. To cut it four times, the summer must be very favourable, and the last cutting will be late. Here I must remark, that lucern is not only excellent as a green fodder, but as an early one, especially if sown in drills, or transplanted; for that sown in broad-cast will not be fit for cutting so soon as the former, by a fortnight or more; however, the farmer may depend on three good crops in this manner of sowing.

In the spring 1760, Mr. Rocque sowed about five acres with lucern and barley: the land is light and hot, but being in good heart, the barley was rank, which obliged him to mow it green, and sell it to a farmer for feeding cows, &c. Indeed I believe it will always be best to do so; for the weeds, if there are any, are thus cut down, and the lucern thrives apace. The spring following, it may be harrowed with light harrows, and every year after with such harrows as you find clean it best. Last autumn, when the weather was hot and dry, I saw a farmer harrowing Mr. Rocque's field with large ox-harrows, and I do not perceive that it is at all hurt. The weeds and trumpery were raked up, and carted to a dung-hill, with which he has this spring dressed his field, and it is now in a fine thriving condition.

Lucern makes most excellent hay: horses are very fond of it, and, with one quartern of oats, I will be bound any gentleman will be well satisfied with the condition of his horses, even coach-horses; nor do I see it is at all more difficult to be made into hay than clover. *Museum Rusticum*, vol. IV. p. 307.

Experiments on Lucern, by Mr. John Wynne Baker, published by the Dublin Society.

The inestimable value of this plant has been so much spoken of by all the ablest writers on husbandry, that it is quite unnecessary for me to say any thing in its recommendation.

Here follow my experiments upon it this year:

No.

15. Sown in drills, three feet asunder.
16. Sown in drills, two feet asunder.
17. Sown in drills, one foot asunder.
18. Sown in the common or broad-cast way.

I sowed the seed for these experiments on the first of May, but the middle of April would have been a more proper season.

The lucern began to appear on the eighth day: in its first appearance, it has two very small leaves of an oval form.

These experiments were treated in the same manner as the burnet.

On the sixteenth of August, I cut the lucern of each experiment, and the produce of green fodder was as follows:

- Number 15. i. e. the three-feet drills, produced off one perch, thirty-one pounds and a quarter.
- Number 16. i. e. the two-feet drills, produced off one perch, forty-four pounds and a half.
- Number 17. i. e. the one-foot drills, produced off one perch, forty-three pounds.
- Number 18. i. e. the broad-cast, produced of one perch, fifty-nine pounds.

Upon the face of these experiments, the broad-cast has the greatest produce. Above the three-feet drills, twenty-seven pounds and three quarters; above the two-feet drills, fourteen pounds and a half; and above the one-foot drills, sixteen pounds.

Hence it may be concluded, by persons not acquainted with the nature and culture of this plant, that the broad-cast sowing is to be preferred, as yielding the greater produce; but I think that conclusion should not be too hastily drawn, for the following reasons.

These crops are all from the first cutting after sowing the seed, and therefore the lucern in the broad-cast was then as good, or probably better, than it will ever be again

in any succeeding crop, the ground being looser, and fewer weeds in it, than there ever can be hereafter; for the natural grass is already rising in it, although it was managed in the way practised by Mr. Rocque; which is to harrow, or rake the ground after cutting the lucern. Another reason is, that for the first year the plants are in their infancy; but in three years I apprehend the drills will more than treble their produce; whereas, at that time, I should fear the broad-cast would be quite or near destroyed by the natural grass. In other words, as fast as the drilled crops improve, I do conceive the broad-cast will diminish.

The culture of lucern in drills, with intervals of only one foot, I find is no better than the broad-cast, as there is no such thing as horse-hoeing between the rows, and where the crop should be large, digging would be too expensive.

But upon the comparative experiment, between the two and three feet intervals, I confess I cannot so readily pronounce; the two feet produce the most, by thirteen pounds and a quarter; whether that distance will continue to do so, I cannot say: it may happen that when the roots become large, which is the properest time to ascertain the fact, that the three-feet drills may have the greater produce: but time alone can determine the point, which really is very material to know.

Second Set of Experiments on Lucern.

These experiments were calculated to discover how far the roots of this plant would bear being wounded, as in the culture of lucern practised by Mr. Rocque: I do conceive many of the roots must be injured, to the manifest diminution of the crop.

In April, 1764, I sowed a little lucern in my garden. May the 1st, 1764, I treated some of the plants in the following manner, after thinning of them in the row, by taking all others from them, and leaving the plants single, and two feet asunder.

- Numb. 1. The root of this plant I split from the crown of it downwards, for about an inch.
- Numb. 2. The root of this plant was split first in the same direction as the former, and then I split it transversely, for about an inch downwards.
- Numb. 3. The root of this plant I cut a slice off one side, about an inch long, just below the crown of the root.
- Numb. 4. This plant I cut the whole crown of the root off.
- Numb. 5. This plant I split the root of, in the same manner as Numb. 1. and then cut about an inch and a half off one side.

After wounding these plants, I dug the earth round them, in order to feed the fibrous roots in the nourishment of the plants.

They never afterwards made any figure. Towards September, Numb. 1, 2, and 3, threw out a few weak stems, not worth notice; but Numb. 4, and five, never grew afterwards.

These experiments I mean to repeat in a greater number, and that for two or three years together, before I shall venture to draw positive conclusions from them; but I think these seem to prove, that Mr. Rocque's method is not to be preferred so much beyond Tull's, Duhamel's, and M. de Chateauvieux's, as his advocates would insinuate. But the fair trial between his method and the drill, will be to experiment carefully upon them for four or five years together; my experiments in wounding the plants, being only calculated to support theory by facts; for my notion of the consequences which must happen from his culture, is no more than theory.

Till I made this set of experiments, I confess I never was sensible of the texture and firmness of lucern roots, which are really very hard to cut, and not much unlike a dried stick, which I must confess seems to favour Mr. Rocque's method, so far as relates to my apprehension of the plants being wounded by his instruments, which, from the hardness of the roots, cannot wound them in the manner I did mine with a knife. And as my pursuits tend only to discover the truth in matters of husbandry for Mr. Rocque's honour, and my own credit, I could not omit to communicate this remark, as I hope the reader will believe I am endeavouring to ascertain the best culture for lucern, and not writing to lessen Mr. Rocque or

or his system: every man acting in a private capacity, has a right to adopt such as he pleases; but I, who am acting in a great measure for the public, think myself bound to be conscientiously exact in my scrutiny of every system which I shall comparatively experiment upon. If I am mistaken in the culture of lucern, I have the satisfaction of considering some of the greatest men, who have ever wrote upon the subject, are no less mistaken than I am.

Notwithstanding all that has been said by many writers on lucern, as to its tap-roots, yet I find it has many lateral ones, and it is only a few of the plants that send down but one tap-root, but an infinite number in all shapes and directions. At a year old, I find the healthy ones are from ten to eighteen inches long; I preserve them of that age now by me, and intend every year to take them up, in order to have them of all ages, the better to see their progress from year to year.

Upon the first of last May, some of my lucern, which was sown the year before, was eighteen inches high: but let it be observed, that it had the benefit of a south aspect, aided by the reflection of a fruit-wall. This induces me to believe, that a declivity with a south aspect will be the most advantageous situation for this plant, in this country; for, although lucern will live in the severest winters, yet it flourishes best under the influence of a warm sun; the only blessing we seem to want in this country.

In the summer months, I observe, in a good soil, and under proper culture, it grows about an inch in twenty-four hours; sometimes I have known it grow an inch and a half in the same time.

Third Set of Experiments on Lucern.

The transplanting lucern seems to have been first thought of by the ingenious and never sufficiently to be praised M. de Chateauxvieux, whose reasons for every new attempt are founded upon such solid and rational principles, that they have generally succeeded to his expectations. This gentleman says, plants of two or three years old may be planted equally well with those of one year old.

My plants last April were all one year old, which, upon taking up for the purpose of transplanting, I found differed very much in their size, which induced me to divide them into three parcels, *i. e.* the smallest, middling, and largest. These I transplanted in the following manner, six inches asunder in the rows, and the rows three feet:

- Numb. 1. Forty of the smallest plants, with their tap or leading roots cut off.
- Numb. 2. Forty of the middling plants, with their tap or leading roots cut off.
- Numb. 3. Forty of the largest plants, with their tap or leading roots cut off.
- Numb. 4. Forty of the middling plants, without cutting their roots.
- Numb. 5. Forty of the largest plants, without cutting their roots.
- Numb. 6. Forty of the smallest plants, without cutting their roots.

These six rows of plants were put down the twenty-eighth day of April. I watered them at the time of putting down, and once afterwards.

Very few of them died; so that the different sizes and methods seem to answer equally well the first season.

I intended to have cut the produce of each experiment for weighing; but a few days before that was to be done, my horses got into the place where it grew, and eat some of it, which disappointed my purpose. From the appearance of the experiments respectively, there would have been very little, if any difference, in the produce; but a third and fourth year's crop will ascertain how far cutting off the tap-roots will benefit the plants, and how far transplanting is preferable to sowing. Be it noted, that the transplanted roots make no great figure the first year.

In order to ascertain, with some degree of certainty, how far lucern may be worth the farmer's attention, I last summer made an experiment with an horse, to discover how much he would eat; which being known, we can, from the first set of experiments, pretty exactly tell how many horses an acre of lucern will maintain during

the summer months. The horse I chose for this purpose is a very large one; he had been ploughing from seven o'clock in the morning till seven in the evening, during which time I forbid his having any thing to eat. When he was taken out of the plough, I ordered him to a stable by himself, where I had provided for him fifty-six pounds of lucern, without any other food for that night, of which he had eat by next morning, forty-nine pounds; a quantity, which I own surprised me.

Lucern will in this country, in favourable seasons, mow four times in a summer after the first year, and we may safely calculate, that at every cutting it will yield half an hundred weight upon each perch, which at the four cuttings is two hundred weight upon a perch in the season, or sixteen tons upon an acre, *i. e.* thirty-five thousand eight hundred and forty pounds. This is a low calculation; but at this rate, suppose five horses to be allowed forty-nine pounds every twenty four hours, which is two hundred and forty five pounds, in that case an acre will maintain them one hundred and forty-six days, which is twenty weeks and six days. No man will contend for it, I believe, that any natural pasture will do any such thing. Add to this profit, the circumstance of making dung all the summer; an object, I am sorry to observe, not sufficiently attended to in this country, amongst the common farmers; if they can make a little for their potatoes, they seem to think of no more.

Lucern should never be sown upon wet or spongy ground, but upon dry rich land, and must always be kept free from weeds.

I sowed some last April in drills, upon ground not six inches deep, above a lime-stone quarry, and it grew very luxuriantly; but the soil is very good.

Turneps are the best preparation of ground that I know of for lucern, particularly if they be raised in drills, in the manner before represented.

My lucern in the broad-cast and one-foot drills, was infected with the rust or mildew, during its growth; this seems to be an objection to the sowing of it with such narrow intervals, or in the broad-cast way, since the two feet and three-feet drills were in the same place, and they were not at all infected with this disease.

An Account of the comparative Advantages of cultivating Lucern, on the Drill and Broad-cast Methods; for which the Society for the Encouragement of Arts, &c. adjudged their Premium of a Gold Medal.

The farm on which the following experiments were made, is a strong clay; a soil, in the opinion of all writers in agriculture, the most unfriendly to lucern. Encouraged, however, by M. Lullin de Chateauxvieux's experiments, the owner was tempted to try how the lucern would succeed when treated in the manner he proposes: and in the year 1761, he sowed a field of about three acres with lucern drills, two feet asunder. During the first year, he caused it to be weeded carefully; and from the places where it grew too thick, he supplied those in which it had failed. After every weeding, he caused the intervals to be stirred with a horse-hoe, resembling M. Lullin's single cultivator, which manifestly revived the plants.

In 1762, the plants throve greatly, being kept clean, and horse-hoed as in the former year; and the Society having published a premium for a comparative trial between lucern sown in broad-cast, and in drills, he determined to try one part of that experiment on this field, and not to bestow on his lucern any manure whatever, or to give it any other help than the horse-hoe.

In 1763, the plants were arrived at a size to yield so full a crop as to maintain five horses, from the middle of May to the end of autumn, or above five months. These horses, though constantly worked very hard, had neither corn or hay given them during all this time; and yet they continued in strength and spirit, and grew fat. A horse which in May was so weak, and in so bad a state of health, that it was thought he could not live, soon recovered when fed with lucern. The plants were in general between three feet and three feet and a half high, at the first and second cutting. The plants made so many shoots, and these shoots branched so much, that in three weeks after every cutting, or sometimes sooner, the intervals quite disappeared; the whole field being so equally covered, that it looked as if sown in broad-cast. December 1763, January and February 1764, having been uncommonly rainy,

rainy, the water stood in some parts of the field; and though there was generally such a declivity as that it might have been carried off, he resolved to let it remain, in order to see what effect it would have on the lucern. When the lucern began to rise in the rest of the field, in spring, he found that wherever the water had stood, the plants were killed. He supplied this loss by transplanting lucern from other spots; and these plants thrived very well. By a continuance of the same treatment, the lucern remained in a very flourishing state: and retained a beautiful verdure and vigour, during the very great drought of the summer 1765. It has yielded four cuttings every year, and sometimes five.

Having observed in a root of lucern, taken up in the winter, that the spring shoots had no connection or concern with the remains of the shoots of the preceding summers, but proceeded from numbers of little tubercles, with which the head of the root was set very thick; it appeared evident, that the plants could not sustain any damage, though covered with a depth of earth during the winter. This suggested a hint, that the intervals might be ploughed as deep as possible early in the winter, turning the earth on the beds; and that by letting the earth remain in this condition till spring, the clay, or strong soil in which the lucern grew, would be mellowed, or loosened, by the winter's frost and rain: and being harrowed smooth in February, the fresh lateral roots, which shoot out in the spring, would find a fine fresh mould to extend themselves in, which must tend greatly to the benefit of the plants. This thought was confirmed by experiment: for the spring crops is amazingly vigorous, ever since this practice was followed, and the shoots, though of great length, and most plentifully supplied with branches, are so strong, that no rain or wind lays them, even when they have stood to be in full bloom, as is the case with part of the first crop; the horses not being able to consume the lucern before part of it is necessarily in bloom. Another advantage arising from this practice is, that the grass which takes root near the plants, and which cannot be otherwise destroyed but by hand-hoeing, is killed by being so long covered with the earth laid on the beds.

In 1761, a spot of ground of an exactly similar soil was inclosed for a kitchen-garden; and there being part of it, which was not wanted for other uses, in the spring of 1762, it was sown with lucern in broad-cast, as a counter experiment to the former. The warmth of the garden, and the partiality of the gardener to this method, who held the field experiments very cheap, gave his lucern every advantage that could be desired. It came up well, and was kept free from weeds; but it neither grew so fast nor so high as the lucern sown in drills. The difference became much more sensible during the second and third years; for in 1764, the field lucern had got the start of it so far, that this did not rise to half the height, nor did it yield a quarter of the quantity of fodder; so that he thought it needless to prosecute the comparison further.

Seeing so very remarkable a difference between the lucern raised in drills, and that raised in broad-cast, he resolved to try what share of this advantage might be placed to the horse-hoe, and what to the distance at which the plants stood; which distance afforded the roots more room to extend in. With this view, in 1764, he sowed a neighbouring field in rows, two feet asunder, intending to horse-hoe one half, and to keep the other free from weeds by hand-hoeing only. The months of April, May, and June, of that year, were so dry that the plants came up thin; and the clay was become so hard, that the horse-hoe could not be made use of till late in the year. Even with this disadvantage there was seen a manifest difference, in favour of the plants that were horse-hoed. The same difference was also observable in the spring of this year: but the uninterrupted drought of this summer has kept the clay so hard that the horse-hoe could not be used.

Computing the rent of the land, and the utmost expence that can attend the horse-hoeings and cuttings, it will be found, that feeding horses with lucern will be a great saving, when compared with the price of the hay and corn, which horses must have necessarily consumed in the same time, being kept to equally hard labour.

The several cultivators of lucern have each recommended some particular method of sowing and cultivating it, either in broad-cast, drilling, or by transplantation; it thrives well in all these methods, but not equally. The broad-cast is easiest to farmers, who are accustomed to sow clover

and other seeds in that way, and the crops are very valuable, but inferior to both the others, in quantity and quality.

Mr. Rocque was a native of France, where they raise great quantities of lucern, and sow it broad-cast; and he recommended that method preferably to all others. At first he cut his lucern five times in the season, but afterwards recommends cutting it only three times, because he says cutting it oftener makes it bleed too much. But in this he seems to speak partially: for broad-cast lucern grows slower than the drilled or transplanted, and if allowed to grow to the proper maturity, namely, till it begins to blossom, the broad-cast will commonly produce but three cuttings in England; and his produced no more, after the first or second year. His objection to drilling it, that the roots are confined in the drills, is a great mistake; for gardeners find no such ill effect in drilling; but on the contrary, they drill many of their crops by choice; and it is a fact, proved by repeated experience, that drilled lucern yields greater crops than broad-cast, when both are tried upon the same land, and sown at the same time.

Mr. Rocque's method was wrong in another respect, viz. in dressing the land with fresh stable-dung, which without doubt is a sure way to fill it with weeds, and should be particularly guarded against in the cultivating lucern, weeds being peculiarly destructive to it, more so than almost to any other crop; and for this reason dung of all kinds are very improper for lucern. Soot, ashes of all kinds, and composts of various sorts of dry manure (that contain no seeds) powdered and mixed, are excellent dressings for lucern, causing it to grow luxuriantly; and a luxuriant growth is the principal intent of manuring lucern.

Mr. Rocque, however, very properly recommends harrowing of broad-cast lucern in order to clean it; for its roots are so tough and hard, that harrowing, and even a slight ploughing, do not much hurt them; but, on the contrary, is of considerable service to the crop, by pulling up some of the shortest roots, and thinning the crop; which will be a great deal too thick, if the land is well prepared, and so much as sixteen pounds of seed is sown upon an acre. It should not be weeded with large heavy harrows the same year in which it is sown, which would pull up too many of the plants: but next year there is no danger. And the best seasons for harrowing lucern, are in spring, immediately upon the breaking of a frost; and in summer or autumn, as soon as a crop is taken off: for at these times the ground is mellow, and the weeds are then most easily pulled up by the harrows. Some have objected to harrowing, supposing that such rough treatment would kill and wound so many of the plants, that the lucern must be of short duration: but experience has shewn this to be an error; and that where the harrowing has been performed with proper care, the broad-cast crops in England have continued to flourish for fifteen or sixteen years; whereof Mr. Young has mentioned some examples in his North Tour, and some have lasted almost as long in Surry: which are great encouragements to farmers to raise this valuable plant in the broad-cast way.

It must, however, be acknowledged, that drilling the seed is a much better way than sowing it broad-cast, and of obtaining better crops; this may be done by close drilling the seed, in rows six or seven inches asunder, and the crops cleaned by harrowing; but better if the rows are two feet or more distant, to be thinned in the rows, and set out to the distance of two or three inches, and the spaces between the rows cleaned of weeds by a cultivator, which will at the same time improve the crops and the land: and in this way the crops are superior to the broad-cast, or close drilled, and is a method of culture very easily performed. But to those who would practise an accurate and spirited husbandry, the very best method of cultivating lucern is upon ridges. M. de Chateaubien in this way obtained above five tons of lucern-hay per English acre, reckoning his crops at an average of four years; and it is remarkable that his crops were improving, though they had no manure, and only hoed with his cultivators; the crop was greatest the fourth year, being at the rate of seven tons and a half of hay per acre. His ridges were a little more than three feet broad, and a single row of plants upon each ridge, and six inches distant.

When lucern is transplanted upon ridges, the roots are shortened to six or seven inches, and the tops to two inches. Cutting the tap-roots makes it throw out many lateral roots, which

which spread near the surface of the ground, where they enjoy the warm influence of the sun, causing the plants to shoot quick, and produce more cuttings in the season, than if the tap-roots descended deep into moist cold ground. This is an advantage that the broad-cast lucern cannot have; but the drilled may, though not transplanted: for by ploughing the earth from one side of the rows, the tap-roots are easily come at, and may be cut with a long sharp knife in October, without endangering the plants, or checking their growth.

M. Duhamel had forty tons of green lucern upon an English acre, which he computes at ten tons of hay; by which it seems that his lucern was full blown before he cut it; for then it does not lose so much of its weight in drying, as if it was cut before it blossomed: for forty ton cut just before it begins to blossom, will waste to about eight ton, in drying to hay: but it should be always cut before it blossoms, as it is then in perfection. It was cut four or five times in the season by these gentlemen, and produces as many cuttings here, and in some summers more. Mr. Donnellon, at Artane, near Dublin, who had long cultivated lucern, writes, "that good lucern the second year should yield three pounds and an half to a square yard, and says, I have frequently had it so. I cut some drilled, and some in the random way in August, both sown the April before; the drilled weighed one pound and a quarter the square yard; the other not half as much. Thorough saved hay made of it is not above a fifth of the weight when it is cut." He cut his lucern four or five times in the season; and the produce, in the above proportion, was six tons of hay per English acre, at four cuttings; and at five cuttings, above seven tons and a half per English acre. This lucern was planted upon three feet ridges.

Planting it upon ridges is the best method of all; but if the ridges are only three feet broad, and the plants six inches distant in the row, the bulbs, or crown of the

roots spread, and in two or three years they meet, and form a row of six inches broad on the middle of each ridge; and then there is not room to horse-hoe them properly, nor earth enough to be hoed; for this reason it is better to set the plants at nine inches distance in the rows, and to make the ridges four and a half or five feet broad. The heads of the plants will soon spread and meet, (for they have been known to spread to a foot or eighteen inches diameter, where they had room, and good nourishment): and when they meet, will form a broad row upon each ridge, of nine inches; and will produce four, five, or six cuttings in the summer, in quantity proportionable to their breadth, and the culture bestowed upon them: and as three feet ridges, and plants six inches distant, have produced above five tons of hay every year, without manure, these well hoed and manured may be expected to yield eight tons of hay every year: for lucern is cut as often, and yields as great crops in England, as in France or Italy. These would produce still greater crops, if allowed more room, which the curious will find upon trial. One great advantage of cultivating lucern in this manner is, that there is not a weed among such lucern, and the stalks are rich and succulent, incomparably nourishing food for cattle, and for foiling horses, superior to any of the cultivated grasses.

That the thick sowing the lucern seed very much lessens the crops, appears very clearly from Mr. Wynn Baker's experiments upon this plant. He sowed some lucern seed in 1764, in drills one, two, and three feet distant, and in broad-cast, all upon the same ground; and he transplanted some of this lucern at one year old from seeds; at the same time shortening the roots to six or seven inches, and the tops to about two inches, as practised by M. de Chateauxvieux. The lucern of these several experiments, growing upon equal quantities of land, were cut all at the same time, and the products were per Irish plantation acre, as follows:

	The three feet drills.				Two feet drills.				One foot drills.				Broad-cast.				Transplanted.			
	Ton.	cwt.	qr.	lb.	Ton.	cwt.	qr.	lb.	Ton.	cwt.	qr.	lb.	Ton.	cwt.	qr.	lb.	Ton.	cwt.	qr.	lb.
1st year, 1764	2	4	2	16	3	3	2	8	2	12	2	0	4	4	1	4	Not cut by mistake.			
2d year, 1765	8	17	0	16	9	10	0	0	8	17	0	16	8	2	3	12	10	12	3	12
3d year, 1766	32	0	2	24	29	10	0	0	31	0	0	0	16	2	3	8	34	12	2	10

This lucern yielded but four cuttings in the year, the land being cold and poor, and lying upon a bed of stone, and but about six inches deep above the stone quarry. It had no manure. The three feet drills, and the transplanted, were hoed with a small plough: the two and one feet were hand-hoed, and the broad-cast was cleaned with a rake.

Here it is observable, that the broad-cast yielded the largest crop the first year; but continued to decline the following years greatly. And the three feet, and the transplanted were also gaining upon the narrower drills, though the narrow had many more plants in them: for none of the rows were thinned; so that the one foot drills had thrice as many plants in them as the three feet drills, and yet produced a smaller crop, viz. the one foot drills produced but thirty-one tons the third year, and the other produced thirty-four tons and a half. But the most remarkable difference is in the one foot drills and the transplanted; this last having only two plants in a foot long of the row, and the other probably more than ten times as many: yet these ten produced not half the crop of the thin plants: but the broad-cast, which was sown thick all over the ground, produced the smallest crop of all; a plain proof that thick sowing diminishes the crops to a very great degree. It also very much lessens the value of the crops; the large plants are by much the most succulent, weighty, and nourishing, and are entirely free from weeds; but the broad has always many weeds, which are a considerable part of the crops.

Clayey or strong land retains much moisture, which makes such land cold, and the crops raised upon it late, and for this reason, though lucern will grow upon strong land, mellow loams are the most proper for it, a warm aspect, and the land laid in ridges, well manured, and frequently hoed; with these advantages it will yield surprising great crops, which it is very capable of producing. In 1765, Mr. Baker observing one of his plants of lucern, which he had transplanted the year before, was very vigor-

ous, he cut it by itself, and it weighed twenty-seven ounces, which at six plants per yard square, is ten pound two ounces per yard, or thirty-five ton, eight cwt. of green lucern upon a plantation acre, at one cutting. He says he knew of no extraordinary advantages which this plant had, unless any accidental quantity of manure had dropped near it. At four cuttings, an acre of such plants would produce one hundred and forty-one ton, twelve cwt. of green lucern in one summer, or twenty-eight ton, six cwt. of hay upon one plantation acre (seventeen ton, fourteen cwt. of hay per English acre) the second year after it was transplanted.

He further observes, that his lucern was not in general ready to be cut till May every year, and produced but four cuttings in the season, but that having transplanted half an acre of lucern, upon land that had a better aspect, (than that of his other experiments) this half acre lying to the south-east, had such effect, that though this soil was rather inferior, the lucern upon it was from ten to fourteen inches high, the 27th of March 1767, its second year from transplantation, and his other lucern was then but six inches high.

Lucern not only produces great crops, but they are also highly nourishing to cattle, more so than any of the other grasses, or than any of the plants or roots commonly given to them, as will appear from experiments, those particularly that have been made by the same accurate experimenter.

He bailed up two of this largest milch cows, and fed them a month with green lucern only; and found, that each of these cows eat eighty-four pounds of the lucern in twenty-four hours, without waste: if he gave them more they made waste. They gave a great quantity of exceeding good milk, and of a good flavour, equal in quality to that from two other cows fed at the same time upon a choice small meadow. Butter was likewise made from the lucern and the meadow, which were both excellent, and of equal goodness. The cows were swelled by eating the lucern, if given them immediately after it was cut; but not if they were fed upon what was cut the preceding day.

Mr. Baker also fed his cattle upon turneps, cabbages, and turnep-cabbages, and found, that a fattening bullock eat a day nearly half his beef weight of turneps, and seven pounds of hay; and of cabbages, and turnep cabbages, three-eighths of their beef weight a day, besides seven pounds of hay: when fed upon turneps they refused water, but drank some with the cabbages. The two milch cows fed upon lucern as mentioned above, he says, were two of the

largest he had, and therefore weighed probably between four and five hundred; but admitting they were only four hundred each, and that a fattening bullock of that weight would eat as much lucern as each of them, viz. eighty-four pounds a day, the daily proportion of these three kinds of food necessary for a bullock of four hundred weight, is as follows:

A fattening bullock of 4 cwt. will consume every day,					
Of turneps	—	2 cwt. or $\frac{1}{2}$ his beef weight, and some hay	—	—	$\frac{4}{8}$
Of cabbages	—	$1\frac{1}{2}$ cwt. or $\frac{3}{8}$ of ditto, and ditto	—	—	$\frac{3}{8}$
Of lucern	—	$0\frac{3}{4}$ cwt. or $\frac{3}{16}$	—	—	$\frac{3}{16}$

By which it appears, that lucern goes above twice as far as cabbages in feeding bullocks, and still further than turneps.

If the value of these crops are estimated in proportion to their produce per acre, an acre of good turneps weighs from twenty to thirty tons; the last is a great crop, and seldom obtained by farmers in the way of hand-hoeing. Mr. Young, indeed, speaks of fifty tons of turneps produced upon an acre, and in that proportion throughout a whole field, but does not mention by what culture, hand or horse-hoed; and there is no doubt, if we compute from the size or weight of very large turneps, an acre may produce that quantity; but certainly in common practice, the crops are rarely so high as thirty tons; and twenty tons may be reckoned the full average of good crops.

Of cabbages the Scotch are the largest hitherto introduced into common culture, and the weight of them is sometimes as high as forty pounds a piece; but the best crops to only about fifty tons per acre, and the average from twenty to forty tons per acre.

Good crops of green lucern may be reckoned from twenty to forty tons, and the average about twenty-five tons per acre, when drilled on the level; but considerably more if upon ridges, and horse-hoed.

A bullock may be well fattened upon lucern in four months, or, allowing twenty weeks to fatten him upon turneps, cabbages, or lucern; he will in that time consume of these sorts of food, in the proportions above mentioned, admitting him to weigh four hundred when fat, the quantities following:

	Cwt.	Cwt.	Ton.	cwt.	lb.
Of turneps, in twenty weeks, at 2 a day (besides $8\frac{3}{4}$ of hay)	—	—	14	0	0
Of cabbages, in ditto, — at $1\frac{1}{2}$ a day (and $8\frac{3}{4}$ of ditto)	—	—	10	10	0
Of lucern, in ditto, — at $0\frac{3}{4}$ a day (no hay necessary)	—	—	5	5	0

An acre of each of these will fatten,					
Turneps,	25 ton per acre will fatten, with hay near	2	fuch	bullocks.	
Cabbages,	30 ton per ditto, ditto, with hay, near	3	ditto,		
Lucern,	25 ton per ditto, ditto, without hay, near	5	ditto.		

All which shew plainly, the superiority of lucern turned, and cabbages, when compared together, either by weight, or by the acre.

Carrots are a very nourishing and hearty kind of food for all sorts of cattle, and are by some so highly extolled, that they may perhaps be thought equal or superior to lucern: but as there are few accurate experiments made of feeding black cattle with them in the comparative way, the value of them cannot be ascertained exactly. The large experiment made by Mr. Billing is not fully satisfactory in this point: for he states his crop, and the application of it in feeding cattle, by the load; but does not mention the weight of his loads, or the weight per acre; which renders the experiment obscure.

We may, however, from what he says of his carrots, approach nearly to their feeding quality. His $30\frac{1}{2}$ acres sown with carrot seed, produced in all 510 loads of carrots, which is about $16\frac{1}{2}$ loads per acre, upon an average. He had long experience of fattening cattle with turneps, and in using his carrots found that one load of them was nearly equal in feeding to two load of turneps, and probably the loads of these two were of nearly equal weight. Now as it appears above, that $\frac{3}{16}$ of lucern goes as far in feeding as $\frac{1}{16}$ of turneps, the lucern is $\frac{5}{16}$ more feeding than turneps, and consequently than $\frac{3}{16}$ of carrots; and therefore lucern is superior to carrots in the proportion of 4 to 3; but by the acre the superiority is still greater; for an acre of land will produce twice the weight of green lucern, as of carrots.

Mr. Baker fattened sheep upon turneps, cabbages, and turnep cabbages. His sheep when fat weighed about 80 pounds each, and they eat daily of

Turneps, 20 pounds, $\frac{1}{4}$ of their mutton weight.

Cabbages and turnep cabbages } 15 pounds, or $\frac{1}{6}$ of their mutton wt.

By this it appears that sheep eat but half the quantity a day that bullocks do in proportion to their weight: so that if sheep can be fattened in as short time as bullocks, fattening sheep is by much the most profitable; for the price of mutton and beef at market is much the same in general, and mutton is frequently dearest.

LUG, or LUGG, the same with pole, or perch, a long measure of sixteen feet and a half.

LUPINES, a species of wild pea, cultivated principally as a manure.

Lupines require the least labour of any thing that is sown; and will thrive in any soil, except the chalky and mirey; but delights particularly in poor, hungry, worn out land, especially if it be dry and sandy. If sown in February or March, after a single very shallow ploughing, and slightly harrowed in, or even harrowed in without any ploughing, it will blossom three times between May and August, and prove an excellent enricher of the ground when ploughed in, just after its second blooming: though Mr. Miller, holding the lupine to be a very great impoverisher of the ground whilst it grows, thinks it is still better to parboil the seeds, to prevent their sprouting, and then to strew about sixteen bushels of them upon an acre of land and plough them in. In warm countries, lupines are much sown in vineyards for this purpose only, and are found to be one of the best manures that can be laid to the roots of the vines. Their seeds ripen towards the end of September, or in the beginning of October. They are very bitter: to remedy which, the Spaniards and Italians, who feed their cattle, horses not excepted, with them in winter, steep them in river-water and salt, till that bitterness is gone, and afterwards dry them thoroughly over a fire or in the sun. They even make bread of them, when corn is very scarce, and put them to several other culinary uses. The best time for mowing them is after a shower of rain, because the seeds drop easily out of their pods when they are gathered too dry. They must, however, be laid up very dry, or worms will soon breed in them. The red, and the blue lupines, which are frequently planted in our gardens by way of ornament, grow wild, and in great quantities, about Madrid.

LYE, a fluid impregnated with salts, &c. See the article STREPS.

MACHINE for ascertaining the force necessary to draw ploughs. Mr. Young, in his Annals of Agriculture, vol. I. says, "that Mr. Samuel More, secretary to the Committee of Agriculture in the London Society of Arts, invented a machine for measuring the force exerted by horses in drawing, that does great honour to his talents. It is a spring coiled within a cylindrical case, having a dial-plate marked with numbers like that of a clock, and so contrived that a hand moves with the motion of the spring, and points to the numbers in proportion as the force is exerted: for instance, when the draught equals 1 cwt. over a pulley, the hand points to fig. 1. when the draught is equal to 2 cwt. it points to fig. 2. and so on.

"Till this very useful machine was invented, it was exceedingly difficult to compare the draught of different ploughs, as there was no rule to judge by, but exertions of the horses as apparent to the eye; a very undecisive mode of ascertaining their force. The society was no sooner in possession of this gage, but experiments were directed to be made, under the eye of the Committee of Agriculture, with several ploughs, on comparison with an iron one sent in by Mr. John Brand for a bounty.

"The committee determined that Mr. Brand's plough was an improvement, and merited a bounty from the Society. The Society at large confirmed the resolution, bought the plough, and gave a bounty of 20l."

MACHINE FAN. See WINNOWER MACHINE.

MADDER, the English name of a plant, cultivated with great advantage in several parts of Europe, and lately in England, being a very capital ingredient in the dying business.

There are several species of madder, all of which afford a dye. M. Guettard, of the Royal Academy of Science, has experienced that the ladies bed-straw, or cheese-rennet (gallium) may be made to yield one; and of this kind is probably the Ray-de-chaye, which is used on the coast of Coromandel for dying red. M. Dambourney has not, indeed, as M. Duhamel remarks, hitherto been able to extract a good colour from the gallium: but there yet remains room to hope he may be more successful in the future experiments which he intends to make on this root.

Mr. Ray mentions and describes four different kinds of gallium or mollugo, bastard madder, which, after the laudable example of our enterprising neighbours, should likewise afford matter of experiment to those who wish well to this country, and particularly to our dyers.

The azala or izari of Smyrna, perhaps more properly written hazala or lizary (according to the eastern method of pronunciation) which is the sort used by the French dyers at Darnetal and Aubenas, to give cotton that fine carnation colour for which Adrianople is famed, is a true madder. Some species of it grow naturally under hedges and in woods: and the roots of these, when carefully dried, yield as fine a dye as the azala of Smyrna. M. Dambourney has cultivated a species of madder which was found growing wild on the rocks of Oissel in Normandy, and the roots of this plant have yielded him as beautiful a dye as the azala of the East. We shall hereafter speak of it in his own words: but in the mean time we cannot help observing here, that Mr. Ray describes particularly a wild madder which grows not only on the St. Vincent's rock near Bristol, but also on the rocks about Biddeford in Devonshire, and in great plenty among the hedges almost all over the country. As Mr. Ray calls this the *rubia filicifolia monspeliensis major*, and as Mr.

Duhamel suspects M. Dambourney's Oissel madder to be that very species, it surely is a matter of great importance to this nation, and well worth the attention of patriots, to follow M. Dambourney's example in making proper trials of it.

The species most commonly cultivated is the *rubia tinctorum sativa*, J. B. III. 2714. and C. B. P. in 333, commonly known among us by the general name of madder. It is of this species that the plantations of madder are made in Zealand, and in the neighbourhood of Lisle.

The following method of cultivating this useful plant was sent to the editors of the Museum Rusticum, by a gentleman who has been a practical grower of madder for several years, and tried it upon land of various kinds.

My first trial, says he, was upon a small piece of ground near my house, of about forty perches of land, lying pretty low and moist, of a deep mellow soil, and rich black mould, inclining to sandy; and underneath, about two feet and a half, and in some places three feet of good earth, was a bed of loose sand, with a mixture of gravel.

I have been the more particular in the description of the nature of this land, because it produced the best English madder I ever had, both as to quality and quantity.

In March I caused this plot to be dug a full spit deep; and as it was under natural grass for some years before, I took care in digging to throw the top turf as low as possible, turning the mould uppermost, in order to prevent the grass from springing; which had the desired effect. I also took care to throw out all the roots of weeds, and other noxious plants which were found therein.

In this state it remained about a month; then with a line I divided it into beds five feet wide, and two feet interval between each bed, raising them a little in the middle with some of the earth in the intervals; then with iron rakes the beds were reduced to a fine garden mould, leaving them a little rounding, like asparagus beds, in order to shoot off the rain water; and having procured some strong packthread, at every foot distance I tied a small piece of white woollen-yarn, and thus continued the whole length of the line, which afterwards served as a rule where to fix the plants.

This line was extended, the whole length, upon the outermost bed, six inches from the side ridge of it; then with iron-shod dibbles a madder-plant was set strong in the ground, near every tuft of white yarn fixed along upon the line.

This row being thus planted, the line was removed two feet forwards which brought it exactly to the middle of the bed; this being also finished, the line was again removed two feet, and planted as before; and this method I continued till the whole was planted. Thus there were three rows of plants in each bed, at two feet distance, and one foot apart in the rows; and the distance between the innermost row of one bed, and the outermost row of the next adjoining bed, was three feet.

During the first summer I kept the young madder quite clear from weeds, by hand-hoeing, as soon as any appeared; and in October following I took the haulm that over-ran the intervals, and spread it over the beds, without cutting any off; then with a spade I covered the haulm with the earth from the intervals, about two inches thick.

In this condition it remained during the winter, and in March following, the young madder came up very thick and strong; and as fast as any weeds appeared, I kept them down by hoeing as before; but in the second summer I found there was no necessity of repeating the hoeing after the

the middle of June, for the haulm was now grown so very luxuriant as entirely to cover the surface of the ground, and thereby prevented the weeds from growing; and in October I again spread the haulm upon the beds, and covered it over with the earth in the intervals, as before.

There are three good reasons for covering the madder in winter.

The first is the new dressing of the beds with fresh untried earth.

Secondly, by this method deep trenches are formed at proper distances throughout the whole plantation, and consequently the beds are kept dry and healthy, and hereby the roots are prevented from rotting, which otherwise they are apt to do, if the water continues too long soaking on the beds.

The third reason is still more efficacious: for by this means the haulm is entirely rotted, and the volatile salts contained therein are washed down to the roots by the winter rains, which tend more to encrease the vegetation of the plants than double the quantity of any other sort of manure whatsoever, and for this reason, because the salt, inherent in the haulm, is of the same kind with that which was before extracted out of the ground by the growing of the madder, and is now returned into the earth again, in order to renew its former office of vegetation.

This, perhaps, may seem new doctrine to most of your readers; but experience convinces me of the truth of it, not only with regard to madder, but likewise in the propagation of asparagus, which, in a future letter, I may, if I have leisure, explain more fully by giving the public an account of my making and managing those beds.

If this hint was duly attended to, it is my opinion that both farmers and gardeners would find their account in it in the production of most sorts of vegetables.

But to return more immediately to my subject.

In the third summer very little work was required, only two slight hoeings in April and May, owing to the strength of the haulm, which covered the ground as in the preceding summer; and in October following the roots were taken up, and this small piece of ground produced one thousand nine hundred and sixty-five pounds of green roots, which were very large, and the madder, upon trial, found to be exceedingly good.

In cultivating madder, great care is to be taken to see that every set or plant has some small fibres at the root; and this ought particularly to be observed by those who are employed in taking them out of the ground; for unskilful persons, not used to the business, very often draw up such as have no fibres at all, and then they certainly miscarry.

The best way is, to remove the earth from the mother-plant with a small hand-hoe, or some such instrument; and then you may easily find which of the young plants has fibres, and which not.

In the second spring you must be cautious not to take off above two or three sets from each root; but in the third spring, when they are deeply rooted, you may take off almost as many as you please, without injury.

The sooner the young plants are set after they are taken up the better; and if you are obliged to have them at a distance, so that they cannot be set again in less than three or four days after they are taken up, they must be well watered at first planting, and repeated as often as you see occasion, till they have taken root.

In dry seasons, the young plants very often die for want of moisture, soon after they are planted; and in large plantations the expence of watering would be too great; therefore I always get my land ready early in the spring, and wait for some showers falling; and when I find them just at hand, and sometimes in the rain, I get a great many hands, and immediately go to work, some taking up, and others raking and planting; so that the whole is soon finished, even a large piece of ground; and when the plants are well watered at first, they soon take root, and afterwards they will stand a dry summer very well.

In the most favourable seasons, some few plants always die soon after they are set; therefore about three weeks after planting, you must go over your madder-ground, and replace such as have failed, with the best and most likely plants; and if the season be dry, let them be well watered at first planting; but if, after all, you find any miscarry, (which in a dry summer they sometimes will do) the best way is to fill up the vacancies with winter-plants in October following, just before you cover the haulm.

Madder may be successfully planted from the middle of March to the end of May, according as the spring is either forward or otherwise; but if showers should happen to fall in April, this is the best month in the year for planting madder. There should be no dung of any kind laid upon the ground during the time the madder is growing, because it has been found to give the madder a bad colour; and if the land is in good heart, and proper for the purpose, there will be no need of it.

It cannot be expected that any land, even the richest, should produce repeated crops of madder; for which reason, I am told, that the Dutch always allow an interval of six or seven years, in which time they manure the land very well, and sow it with corn or garden vegetables, and have always large crops, owing to the deep stirring of the ground, and being clean from weeds; and I can, from my own experience assert, that the best crops of corn always succeeded a madder-crop.

About five years ago, I planted an acre of madder on a light, dry, sandy soil, which produced a tolerable crop, but nothing equal to the other.

I likewise tried it upon an acre of land of a loamy mellow soil, somewhat sandy, about a foot deep in mould; and underneath it a cold, stiff clay: from this piece I had great expectations, as the plants thrived very well at first, but in the second summer, when the roots reached the clay, the plants died away, and came to nothing; therefore I am well satisfied a cold clay is by no means proper for madder.

I have also at this time, two other acres of madder, which I intend to take up next winter; it will then have stood three summers. The soil is a deep, hazel mould, worth about twenty shillings per acre. Instead of digging it with a spade, I plough-trenched it at least eighteen inches deep, but managed, in all other respects, like the former. From the appearance it made last summer, I have no great expectations from this plantation, though I fancy it will be a saving crop.

Expences attending the Culture of an Acre of Madder, supposing the Land to be worth forty Shillings per Acre.

Produce of an acre of madder	—	—	52 12 2
Expences	—	—	15 18 2
Clear profit	—	—	36 14 0

In the business I follow, which is that of a clothier, a great deal of madder is used in dying; and being of opinion

nion that there are many useful discoveries now lying dormant, only for want of proper methods to bring them to light, I determined to try an experiment on madder; accordingly I took twenty pounds of the green root, and having washed it clean from dirt and filth, I bruised it in a large iron mortar, just before using, and with other ingredients I dyed half a pack of wool of a dark full drab: upon examining my colour, I found it full as good as though I had used four pounds of the best umbro madder, imported from Holland; so that according to this calculation, which is founded on experiment, five pounds of green madder-root is equal to one pound of dry manufactured madder: and as I have found this method to answer, I have continued to use the root in this condition ever since, and find it much the best and cheapest way; for the green root is bruised very easily in the mortar, and thereby saves a great expence in drying, pounding, &c.

Before I quit this subject, I would advise those persons who are inclined to cultivate madder, to be very cautious in the choice of land for this purpose; for hereon their success chiefly depends. Madder being a plant that draws a great deal of nourishment, consequently the richest and deepest lands are to be chosen, and such as lie pretty low; for high lands are seldom fertile.

The following method of cultivating madder was communicated to the public by M. de Salens, a French gentleman, who is well acquainted with this branch of husbandry:

"I am apt to think, says he, there is hardly any kind of soil, but what madder will grow in; but it does not thrive alike in all: on the contrary, scarcely any plant sooner discovers the richness, or poverty of the land, by the state of its growth, than madder; in rich land, and a soil that agrees with it, it is luxuriant, and produces a great number of sizeable, well-conditioned roots; but in a poor, dry, hungry soil, the plant is visibly checked in its growth, and the roots of it are small, and few in number.

Madder is a great friend to moisture, and therefore thrives best on a good loam, with a clay bottom. It is very fond of fresh land just broke up; but it must be so situated as not be subject to be overflowed, as that will destroy the plant.

Madder requires, to come to a state of perfection, a great deal of nourishment: yet it is said not to impoverish the land; and this, in fact, is evident; for when the madder is dug up, the earth will be in excellent condition to bear a good crop of wheat.

I have tried several ways, and at length am of opinion, that the best method of raising madder in France is from the seed: it occasions, indeed, at first, some delay; but by continuing to sow a quantity in the nursery every spring, you will never fail to have plenty of plants.

The seed must be sown on a bed of earth, dug well, and made very fine with the rake, with which instrument the seed must be slightly covered.

When the plants appear, they must be carefully weeded, and set out with a hoe: the bed must, during the whole first and second summer, be kept very well hoed, and clear of weeds; and if this is done, they may be planted out the second autumn.

I have many reasons for preferring this method in France; but I shall forbear giving a detail of them, because my opinion, with respect to planting madder in England, is different.

The seed of madder does not ripen so well with you, as with us; neither does it, as I have been informed, take so well on being sown. For these reasons, I would recommend it to you, to make your plantation with shoots that are put forth by the old roots in spring. I have practised this method, and met with success.

For madder to succeed well, there should be a great depth of good soil, and it should be turned up very deep with a plough, or, what is much to be preferred, with a spade. When the ground is properly repaired, it should be planted with sets, being the spring shoots pulled up in a madder-plot, with some root to them; for, if they have not some root and fibres, they will not take kindly: these shoots generally come from the layers of the plants, and great care should be had in taking them up, or the crop of madder will be damaged: the best way of doing it is with a dibble that has a flat edge, shod with iron; this, on being thrust into the ground, cuts off the roots at a proper length, and by gently declining the handle of the dibble,

raises the set without injuring the fibres of the root; and great care should be taken not to take up too many of these shoots or stalks, as they are undoubtedly necessary to the support and thriving of the principal roots, which, were they deprived entirely of their stalks, would certainly perish.

It is scarcely necessary to inform you, that as fast as these sets are taken up, they should be immediately replanted.

To make the method of planting these sets more intelligible to you, I must observe, that they are planted nearly as potatoes are planted in Ireland; that is, a straight furrow is drawn, the sets are put into it, the earth of the second furrow is thrown over them, the second furrow is filled up with sets, &c. and so on till the whole ground is planted.

We place the sets here within three inches of each other; but this I think is too near for good land: perhaps they would thrive better, was double the space allowed: when three rows are planted a foot asunder, we leave an interval of four or five feet, according to the state of the land."

Grounds planted with madder, always succeed best when gentle rains fall soon after the work is done, as the sets take root the readier, and the whole gets into a thriving state.

In Holland and Flanders, this method of planting differs from that above described: they take up their sets from an older madder ground in May, and they plant them again immediately with a dibble, about three inches asunder, in rows about fifteen inches from each other; they form their beds about ten feet wide, and leave intervals of only one foot and a half or thereabout.

The best time of planting a madder-ground is undoubtedly in autumn, as the sets are then best furnished with roots; and the rain, which commonly falls at that season, forwards their growth.

As the stalks of the madder-plants are to be laid down and covered with earth, the intervals should be every now and then stirred to keep the soil loose. This covering is done when the stalks are about fourteen or fifteen inches long: after the ground has been well cleared of weeds, a part of the shoots in each row is laid down in the intervals on the loose earth, and slightly covered with the same earth; observing, however, not to cover them entirely; the end of each shoot should be left out of the ground, or they will not grow, and the whole work would be thrown away. The intention of laying these shoots down is, that they may be converted into roots, and thereby increase the quantity for sale; but all the shoots should not be laid down, or the disproportion betwixt the stalks and the roots would be too great.

This work may be done with great ease with the common implement, let a furrow be opened close to each side of the bed with a plough: in these the shoots are laid down, and covered slightly with a hoe.

None of the stalks of the madder should be pulled up the first year, as it will too much weaken the roots by disturbing them, and tearing off their fibres.

After laying down the shoots the first year, the madder-ground requires no farther care, except being kept clear of weeds; and in the autumn of the succeeding year it may be taken up, in order to its being prepared for sale: the earth of the intervals must always be kept loose by tillage.

When the madder-roots are taken up, the whole land gets a thorough ploughing, and some fresh roots or sets are regularly planted in rows, in the intervals of the former year; and when this second crop of madder is off, the land will be in fine condition to bear excellent crops of corn; for madder is no impoverisher of land, and the frequent tillage it requires, brings the land into fine tilth, reducing it into as small particles as the bed of a well-kept garden.

The best husbandry is, not to plant the same land in madder for many years afterwards: and whenever it is again planted with that crop, it should be well dunged, manured, and tilled the preceding year.

When the stalks begin to wither, that is, about the latter end of October, the roots are to be taken up; and the cheapest and shortest way of doing it, is to loosen the earth with a common plough, first taking off the earth-board and coulter: when the earth is thus loosened, women and children may serve to pick up the roots; and whatever difficulty occurs, the labourers turn up the soil with their spades.

But a much better, though rather more expensive method, is to have the earth of the beds turned into the intervals with a three-pronged fork: by this method the roots are taken up almost without damage; and many which lie a little deep are saved, but which would otherwise have been left in the ground and lost; and particularly most of the vertical or tap-roots are got up.

When the roots are taken up, they are dried as much as possible in the air, afterwards carried to a kiln, and lastly to the mill to be ground.

A light loamy soil is better for madder than a rich strong clay; it loves moisture, but is killed if it is overflowed: therefore, if the soil is in other respects proper, but too wet, it must be first drained, or at least the beds must be raised high, and the intervals sunk low: on the other hand, if the land is too dry, the intervals may safely, and even profitably, be raised above the beds: this will at least prevent the young fresh planted sets from being hurt by too much drought.

When the upper stratum of soil is deep, it is to be observed that the land cannot be stirred too deep: the only thing to be apprehended is the expence of doing it; the more the earth is reduced, the more nourishment will it afford to the roots of the madder; they require a great deal; but in general madder pays well for any labour that is bestowed on it.

Dry weather is, if possible, to be chosen for taking up madder roots, as the earth then easily falls off them, and they need not be washed, which is to be avoided; and, in fact, there is no occasion to wash them, unless they grew in a stiff soil, and the weather was very wet when they were taken out of the ground.

Some judgment is required respecting the time of taking up these roots; I have already mentioned that they will, in general, be fit for use by the latter end of the second autumn: but this is not always the case; and it is much better to let them lie in the ground another year than to spoil a crop.

The Dutch often take them up too small, and the French almost as often let them grow too large. The two extremes are equally to be avoided: the proper time to take them up is, when they are about the size of a swan's quill; they then yield most dye, and are of course most proper for use. The time when they arrive at this proper state depends not only on the nature of the soil in which they have been planted, but also on the good husbandry that has been bestowed on the land; for without proper tillage they will turn out but an indifferent crop; but if they are planted on a good loam, are well tilled during their growth, and have favourable seasons, they need never be left in the ground longer than the end of the second autumn, whether they are planted in the spring or the autumn.

I have mentioned in this letter many things which will appear trifling to you, when experience has made you more knowing in this culture; for depend upon it, a greater portion of knowledge is acquired by a little experience than by a great many precepts; the first makes a deep impression on the mind, whilst the latter are soon chased away by new, and perhaps more pleasing ideas.

I would recommend it to you, when you begin to plant madder, to depend more on the judgment you shall form of things, than on any thing you can read on the subject. If you miscarry in some instances, you will certainly rectify matters in your future practice: a sensible man cannot be long in the wrong.

I have not, I know, given you any systematical instructions in the affair of cultivating madder; and this I purposely avoided doing; for, had I attempted telling you in what manner this useful plant ought to be cultivated in England, I should certainly have miscarried, and all I could have said would have amounted only to probable conjecture: had I, on the contrary, given you a circumstantial detail of our methods of practice here in France, it would only have served to mislead you, so much do the climates of the two countries differ. I am therefore in hopes, that my manner of treating the subject will be not only more agreeable, but more useful to you, as I have, for the most part, only mentioned such circumstances as may be equally useful in the culture of this plant in both countries.

Lay it down as a maxim, that the culture of madder, if properly managed, is very profitable; there are few crops pay better; but then the two extremes are to be carefully avoided; we must not let our expences be so large as that no crop will repay them; neither must we be so sparing

as to baulk the growth of the plant for want of proper tillage. A great deal is required, yet too much may be bestowed on it, for the reason above-mentioned: the golden mean is best in this, as well as in all other matters: and what this mean is, can only be learnt from experience; for it is absolutely impossible to lay down maxims that will suit all countries, all climates, and all soils.

What has hitherto been said relates to the common way of cultivating madder; we therefore shall now give, in his own words, the great improvements made in this article by the ingenious M. Dambourney.

"M. Rondeaux, says he, found, eight or ten years ago, on the rocks of Oissel, two plants of madder, which he took up and set in his botanic garden. He afterwards gave me some slips of them, and I planted them in a similar place, out of curiosity: but M. Duhamel's Treatise soon made me perceive the importance of cultivating this plant. I accordingly applied myself to it: and by following all the methods which had been pointed out to me, and those which seemed to coincide with them, I succeeded so far as, in four years, to have plants enough to try this culture in the open field. In the mean time I learnt that M. Peter Dupont cultivated with success, at Elboeuf, plants of madder which he had received from Lille in Flanders. He was so kind as to make me a present of an hundred sets of them; and this little reinforcement, added to what I had raised of my own, obliged me to seek for room in my garden at Oissel, wherein to extend this culture. Finding no other spot vacant there, but two walks, I sacrificed the pleasure of enjoying them, to my then new and prevailing inclination. I therefore dug up one of them, the soil of which is a yellow and sandy clay, underneath which, at a spade's depth, is a bed of large gravel, close knit with very strong earth: but I did not suffer this to be broken into. I divided the walk lengthwise, and, without dunging it at all, planted in December 1757, in one half of it, first the sets which I had received from Elboeuf, and then immediately after, but without mixing them, those which I was able to take from my own plantation. The other half of the walk was sowed in the month of April 1758, with seed which I had gathered from my own plants. The other walk was disposed of in the same manner, as fast as I could get plants or seed to stock it; taking care the first year to keep my beds well weeded, and to lay down the branches as fast as they shot out.

"So early as in the autumn of 1758, I gathered seeds from my plants of Oissel madder, whether raised from seeds or from slips; but that of Elboeuf had not then blossomed, though it had put forth stalks three feet high; and even in 1759, it produced blossoms on only a few stalks, whilst the Oissel madder was loaded with them. When the stems were withered, I had the curiosity to take up some of the roots, and was thereby informed of the following interesting facts.

"1. Though it is said positively, in the Dictionnaire Encyclopedique, that madder raised from seed requires five years to grow to the same size as that which is raised from slips attains to in eighteen months, yet I found all things equal in this respect; and if there was any sort of advantage on either side, it was in favour of that which had been sown: both the one and the other occupied the whole depth of the ground so far as it had been loosened, and their roots had, in several places, penetrated through the hard bed of gravel underneath: but in order to pierce through it, three or four roots had twisted themselves together, and shaped themselves exactly to the form of the passage they found between the pebbles, in consequence of which they were more or less choaked there; though they afterwards resumed their natural shape and plumpness in a bed of small pure sand which lies underneath the hard bed, and in which I have been obliged to leave some of them at the depth of four feet.

"It is plain therefore, from this instance, that no time is lost by raising madder from the seed, and that this plant may be raised successfully in the most indifferent soils, even without the help of dung.

"2. I took advantage of some fine days to dry in the sun, but separately, the roots which I had taken up. Every thing seemed to give the preference to those of the Elboeuf species. They were larger and redder than the others, and their powder was finer to look at: but the effect proved very different. To make a fair comparison of them, I dyed, with equal quantities of each of these sorts of madder, two equal parcels of cotton prepared in exactly the same

same manner: that which was dyed with the madder originally of Oissel took a much brighter colour, and resisted during thirty minutes a boiling which the other could not bear during ten. I likewise compared its effect with that of the lizary or hazala of Smyrna; and the advantage as well in point of brightness as of the durability of the colour, was also on the side of the Oissel madder.

"This valuable kind appeared to me from that moment to deserve the preference. In the spring of 1760 I sowed all the seed I had of it, part upon hot-beds, and part on beds in my kitchen-garden; and I desired M. Rondeaux to help me to find out more plants of it upon the rocks of Oissel or of Orival: but he assured me that he had searched for such several times, in vain: nor was he more successful in a journey which he took thither last August, with M. Dangerville.

"I therefore determined to have recourse to the suckers which grow around these plants: but though I took them up as carefully as possible, I could scarcely get any that were rooted; and notwithstanding that most of those which I did plant were yellow for the length of from four to eight inches, yet nine of them in ten died. The off-sets of the Elboeuf madder, on the contrary, though taken up with but little precaution, have a great many fibres and young roots, and their taking fresh root is sure, provided they are planted in cool weather. Nature seems then to compensate the cultivator for the scantiness of the seed which this last species produces, whilst the other yields it in abundance.

"Not to neglect any means of multiplying the Oissel madder, I dug up a small spot of it, about the fifteenth of last June, and took from thence all the slender roots, which run in great plenty just below the surface of the ground: I cut them into pieces at every second joint, and planted them the same day in channels, where all those that were brown and woody became good plants, and those which were then only yellow and tender, rotted.

"The doing of this taught me what I had not learnt from M. Hellot's memoir, nor had any of my correspondents in Holland informed me of it; namely, from what part of the root it is that the most valuable colour is obtained. After all my runners were thus taken off, and replanted, there still remained the stock, furnished with lateral and with descending roots, resembling in form and colour large earth-worms. In three days of sun-shine they were dry, and the parenchymæa, or pulpy part of the root, being then lessened in bulk, the outer skin became wrinkled, because it was then too large. To clear them of this wrinkled skin, I had recourse to a method first thought of by M. Paynel, of Darnetal, which was, to put these roots in a large sack of coarse canvas, and to shake them strongly therein. The friction of the sack, and of the roots one against another, took almost all that outer skin, which I afterwards separated by winnowing, and what then remained, was that which alone ought to be called fine and true peeled bunch-madder, the effect of which is as superior to that of the azala, as the azala is superior to the finest Dutch madder. I would not however advise the cultivators of madder to follow this method, any farther than there may be curious and nice buyers ready to give them a price proportioned to the expences it occasions.

"By thus taking up each species of madder in the spring, one has, as M. Duhamel gives room to hope, not only the advantage of obtaining suckers and joints of roots for raising new plants; but also, if the season be not quite unfavourable, one may dry the root itself in the sun sufficiently to make it keep, and by this means the expence of drying it with fire in a stove is saved, and the injury which the fire does to the quality of the madder is avoided. The colouring part would be still more valuable if the root were dried in the shade, under a shed open on all sides; and to accelerate this drying, I have successfully made use of a bed of half-baked bricks, upon which I have spread the fresh roots. A bed of dry ashes, six inches thick, may also be used; but in this case it must be covered with cloths upon which the roots must be laid, that the ashes may not mix with them when they are turned. A floor of plaster likewise facilitates this drying; and I believe it far preferable to bricks, on account of the ferruginous parts which these generally contain.

"The principal difference which distinguishes the Oissel species is therefore observable in its roots, which are slenderer, of a less bright colour, less furnished with fibres

at their joints, and those joints farther asunder than in the Elboeuf madder: but besides this, an attentive eye will discern many more distinguishing marks.

"In the spring of the second year it rises ten or twelve days earlier than the other sorts, its stalks are slender, and they trail upon the ground as soon as they are a foot long; its leaves are of a pale green, long, narrow, thin, waved along their edges (pretty much like that of the laurel); its blossoms are disposed in loose spikes, and each of the seeds which succeed those blossoms stands upon a pretty long foot-stalk.

"The Elboeuf madder, which comes originally from Flanders, and is the same as the Flemish refugees carried into Holland, puts forth, on the contrary, strong stalks, which have frequent joints, and are able to support themselves even when they are two or three feet long. Its leaves, which are of a deep green, are thick, broad at their base, and terminate in a point almost like the leaf of the great myrtle, and they are not at all, or very little, waved. It does not blossom till the second or third year: its flowers are very apt to fall off, and when this accident does not happen, its seeds stand on short foot-stalks. This seed grows very well: but the ease with which well rooted shoots are obtained from this species renders it the less valuable.

"In order to enlarge my plantation, and likewise in hopes of enriching it with a new species, I wrote to Smyrna for some seed of the azala or azary, and luckily received three pounds of it on the 20th of August, 1760. It seemed to be absolutely like that of the Oissel madder, and I ventured to sow a small part of it, on the 27th of August, upon an old hot-bed which had lost all its heat. It rose well, and the young plants were not injured by the winter. I transplanted them into open ground at the end of last February; they are now in bloom, and their appearance is exactly like that of the Oissel madder, excepting that their stems are slenderer.

"As to the culture, I set out with scrupulously observing M. Duhamel's directions: but afterwards I ventured to deviate from them in some points, in order to adapt it to the less attentive genius of our farmers. In the first place, I have experienced the truth of what M. Paynel of Darnetal observed to me, viz. that the plants which are raised from layers, at a great expence, produce only long woody roots, which yield hardly any colour, remain hollow during two years, and produce very few of those vermicular roots, which are the only valuable ones. I have therefore quadrupled the number of plants in a given space; the ground has been well filled with them, and the expence of making layers has been saved; and, thoroughly to accommodate the culture of this plant to the practice which our country people are accustomed to, I have either planted the slips, or sowed the seed, in rows after the plough, as is done for kidney-beans; and the workman used to earth up these, performs mechanically the same operations for the madder, the expence of cultivating which in this manner is no more than that of raising those beans in the field.

"Having observed that the east winds in the spring, and the heat of summer, are equally fatal to whatever is then set in the lands about Oissel, and that, on the contrary, whatever will bear planting in the autumn succeeds very well in them, I took up, in October last, all the plants of two years old madder that were in my garden-walks, and these afforded me as many slips as were sufficient to plant half an acre of ground. Very few of them failed, because they were all brown and woody. As the roots which are taken up in autumn, and which one might wish to be able to keep, cannot be dried without fire, it is advisable to dig up in that season only the quantity necessary to furnish sets for replanting, and from June to September to take up what is intended for sale.

"On the 16th of last February I sowed in a hot-bed the greatest part of the lizary seeds which I had received from Smyrna, and the rest of them a fortnight after, in one of the beds of my kitchen-garden. I raised from them plants enough to stock four hundred and forty square feet of ground, in an open field, where they succeed perfectly well: but this transplanting checks their growth; so that if the seed is sown in the field in May, the crop will be in nearly equal forwardness: but I have not had cause to approve of sowing earlier in open ground.

"As it is right to make even inconveniences become lessons of instruction, the impossibility of drying without fire the roots which I took up in October, put me upon trying to use them fresh, in the state they were when dug out of the ground. I therefore washed them well, that no earth might remain upon them: but having myself experienced, that, as M. Duhamel observes, this root loses seven eighths of its weight when it is dried sufficiently to be reduced into powder, I judged that I must proportion my quantity accordingly. I therefore put into a quantity of liquor, which would have required a pound of powdered madder, eight pounds of fresh roots bruised in a mortar, and with this I dyed some cotton, in the usual way. When the dying was finished, I found that the liquor was still over-charged, though the cotton had imbibed so deep a dye as to require two boilings to bring it down to the usual colour: upon which I repeated the experiment with six pounds, and afterwards with four pounds, and I found that this last proportion of undried roots is that which gives a colour equal to what is extracted from a pound of dried and powdered madder. One half of the quantity of roots commonly used may therefore be saved by dying with them when they are fresh dug: but, though this is a great saving, it is not the only one.

"1. There is no need to build kilns or sheds for drying the roots in changeable weather.

"2. One is exempted from the inconveniences of a too hasty or too slow drying, either of which is equally hurtful to the quality of the madder.

"3. The waste occasioned by the peeling, garbling, winnowing, &c. of the roots, in the doing of which many, if not all of the small ones that are not, for example, thicker than the straws, are separated with the refuse parts, and thereby generally lost, is hereby saved.

"4. The expence of grinding is saved, together with the waste and fraud which may be committed at the mill; and likewise the inconvenience of waiting till the mill is at liberty, which is of no small consequence in places where there are not mills appropriated to the grinding of madder only.

"5. Lastly, the roots thus used do not evaporate or ferment, as the powdered madder always does, if it be not speedily used.

"All these advantages put together may be deemed equivalent to a saving of five eighths in the quantity. The planter who knows how to dye, may reap the benefit of them the moment that his roots are large enough to be taken up: the dyers by trade will by degrees be sensible of the advantage, and share the profit of the planter, when the madder-grounds are nearer them: they will even find themselves under a necessity of so doing whenever this method shall become general, and this will be a means of rendering it such; for as there is no particular time to be waited for in order to the madder's acquiring maturity, after it has been planted eighteen months, the husbandman who carries a parcel of fresh roots to market will be sure of selling them in that state, and the dyer may buy them daily, in proportion to the quantity he wants; or he may agree with the planter for such and such quantities to be delivered to him at such and such times. I have moreover experienced that these roots may be kept fresh during several months, by laying them in a hole three feet deep, in alternate layers of roots, and of earth.

"This experiment pleases me again in its tending to lessen the expence of dying, and consequently to reduce the price of our dyed stuffs at foreign markets, by which means our trade with other nations may be benefited: and it is likewise new, since neither M. Hellot nor M. Duhamel have pointed it out. I have also experienced that the Elbœuf madder is very good when it is used fresh; a circumstance by so much the more important to be known, as this species is not only the longest lived of any, but also the most easily propagated.

"The principal difficulty now remaining for me to surmount, is to find out some cheap and easy way of taking up the madder, without leaving in the ground its descending roots, which yield the best colour: for the method which I have hitherto practised has been considerably expensive. M. Duhamel proposes a plough which turns over the earth, without a coulter: but if I may judge from what I have seen, this expeditious instrument can suit none but lands where a clayey bottom hinders the vermicular roots from piercing deep. I wrote to Holland, to know how the Dutch manage in this respect; but those zealous

patriots are very reserved in every thing relative to this plant, of which we let them be the monopolizers: I was answered, that they use the spade and the fork. However, I shall try what my zeal and what incidents may suggest to me, and shall communicate whatever I may find to answer best.

"An objection which may, perhaps, be started against this branch of husbandry in France, is, that there may be danger of its prejudicing that of our corn, which is an article of the greatest necessity. But besides that we have immense tracts of uncultivated lands where it might be established, I can, with M. Duhamel, assert, that the profit of the madder may be had in the best fields of this province (Normandy) without diminishing the crops of the most valuable corn. In effect, it remains in the ground but eighteen months, and after it is taken up, a single ploughing is sufficient to enable the land to produce very fine wheat, without any manure. Now it is the custom in all our wheat grounds to take a crop but once in three years, and this may be had after the madder. Nay, an advantage may be reaped even in the first year, by sowing, between the rows of madder, onions and other pot-herbs, which do not root deep or occasion much shade: but there will be a still greater profit in making it grow jointly with kidney-beans, because the rows being regular, nothing would hinder the after-stirrings, which contribute so much to promote vegetation."

M. Dambourney continued his experiments on madder, and gives the following account of them:

"I have restricted myself to the three species which yield the brightest and most lasting colour: these are, the madder originally of Oissel, that which is sometimes found growing wild in the vineyards of Poitou, and the lizary or hazala of Smyrna. All these bear seed in their very first year, and in the second, one may gather two thousand seeds from a plant which would not afford at most above twenty or thirty slips. The difference between these means of propagation is striking, and ought to be decisive in all countries where the seed ripens well, as it does in almost every part of France.

"The manner of raising it from the seed, as practised by me, is thus: Along a wall which fences off the north wind, let a trench be dug two feet deep, five feet wide, and of such length as may be most convenient; then, towards the middle of February, let it be filled with hot dung of horses or mules, well pressed down, to within about three inches of the level of the ground, and afterwards fill it quite up to the top with fine mellow mould, pressed down gently, and laid smooth with a rake. A bed of this sort is preferable to any other, because a common labourer can make it very well, whereas it would often be necessary to have recourse to a gardener to make a raised hot-bed. The expence is not to be regarded, because this bed may be sown six times in a year, and the mould which may be taken from it afterwards will be worth as much as the cost of the dung. The using of this bed does not at all prevent sowing likewise in the beds of a kitchen garden: but as this last should not be attempted before the middle of March, for fear of frosts, there will be a great advantage in sowing upon the hot-bed; for a month gained in this season is invaluable.

"On the 20th of February, 1762, I sowed upon such a bed some madder-seed in small channels about an inch deep, and three inches asunder. This method is always preferable to sowing in broad-cast, because the seed is better covered, and the weeding is more easily performed. The young plants appeared after nineteen or twenty days, they were watered and weeded when necessary, and on the 30th of April they were fit to be transplanted into open ground.

"As most of our farmers are, unhappily, not able to advance money for a culture from which they have no prospect of reaping a return in less than eighteen months, I tried, last year, what would be the event of sowing madder at the same time as kidney-beans, and in the same furrows of the plough. The beans, which rise in less than eight days, required to be earthed up when the madder had scarcely appeared above ground; and this operation smothered the madder entirely. I therefore judged it most proper, this year, to substitute my young hot-bed plants of madder in lieu of the seed, and accordingly, when the weather was moist, for that is an absolutely necessary circumstance, I set some of my people to plant a piece of ground which had been well prepared for a crop

of dwarf-beans. In each furrow of the plough where these beans were sown, women and children placed the young plants of madder six or seven inches asunder, fixing the root in the bottom of the furrow by means of a handful of earth put around it, and resting the green stem against the side of the furrow, the surface of which is exceeded by at least one row of leaves. The ploughman stopped a little at the end of the furrow, till the whole of it was planted: he then opened with his plough, which had a shifting mould-board, a second furrow, in which nothing was either sowed or planted; and at the same time the earth turned out of this filled the first. A woman finished this filling with a rake, as well as to cover the beans completely as to earth up the plants of madder. The third furrow was sowed and planted like the first, and this was continued till the whole extent of the ground was planted in rows fifteen inches asunder. This work, which did not in the least alter the common method of cultivating the beans (excepting that only two thirds of the usual quantity of seed were used) was performed in five hours, by one ploughman, three women, and three children. The ground thus planted contained upwards of twelve thousand sets of madder; and these had taken fresh root, and had begun to shoot up when the beans rose. It was weeded twice, its surface was stirred, and the plants were earthed up as usual, without any danger. Both thrive well together: the beans were pulled up when they were ripe, and the madder, now sole possessor of the ground, covers it like an artificial grass. The greatest part of it has yielded a little seed. The crop of beans, notwithstanding the drought of this summer, is almost equivalent to the expences, and next year I shall have that of the seed and roots of the madder, at the expence of only a stirring of the surface and a single hoeing in the spring.

"My hot-bed was no sooner cleared, than I sowed it again with madder: but the extraordinary drought of the season obliged me to leave it there till the 6th of August, by which means I lost a crop. I then took advantage of a rainy day to transplant it: and this was done in the same way as before, excepting that the season was too far advanced to admit of sowing beans at the same time. The length of the roots of the madder likewise required more precautions to fix them with the earth at the bottom of the furrow, in which one of the horses being forced to tread in order to open the next furrow, the whole would have been trampled to pieces, or dragged out of the ground. Yet the same number of work-people, as before mentioned, set sixteen thousand plants in six hours. The spot is well filled, and the plants will be strong enough to resist the winter.

"On the 15th of May, being deceived by a small rain, I sowed near an acre of ground in alternate rows, as is practised for beans, but only with madder. I used for this purpose three quarts of seed, which I have much regretted; for the constant drought has hardened the surface of the earth so that the young plants have not been able to pierce through it, and consequently all has been lost. The method which I am now going to relate will prevent this inconvenience hereafter.

"I sowed my hot-bed, for the third time, on the 6th of August, with a design to let the young plants remain there all the winter, and not to transplant them till the end of February: but the nineteen or twenty days which this seed requires, in order to its sprouting, disconcerted me. It was necessary, in that hot season, to water frequently by hand, and this, besides wearing out the gardener, laid bare some of the seeds, which grew no more. It then occurred to me, that this might probably be remedied by sowing seed which had already begun to sprout. Accordingly, I filled the bottom of the box with moist mould a quarter of an inch thick, then covered this entirely with seeds, and so proceeded in alternate layers, the last of which was of mould. I kept this box well watered, though exposed to the sun, and each day I examined the progress of the seed. It was on the eighth that the germ began to appear, and the very next day it was three quarters of an inch long. I seized that instant to lay in channels made in the hot-bed, both the seed and the mould in which it had sprouted: I then smoothed the surface of the bed, and two days after, all the rows appeared distinctly. This method likewise saved me a weeding, which I had generally found to be necessary as soon as the seed which had not been made to sprout before-hand had risen. The growth of the young plants was so rapid, that instead of

letting them remain there all the winter, as I first intended, I ventured to transplant them into open ground on the 14th of last September. Frost is a little to be feared for this last plantation; the event will be a lesson for the future.

"Eight days before these plants were taken up, I laid another parcel of seed to sprout, in the same manner as before, and therewith immediately replanted my hot-bed. It has risen well, and will pass the winter there. I hope (by thus using sprouted seed) to be able next year to raise at least six crops on the hot-bed. I likewise sowed at the same time some of this sprouted seed in a bed of my kitchen-garden, where it rose in four days. I intend also to venture some of it about the end of next April, in a spot with beans; and I presume that as this already sprouted seed will rise sooner than them, the plants of madder will be able to bear the first weeding and stirring necessary for the beans; in which case the expence of culture will be much less than the charge of removing the young plants, and both the hazard and the delay of their taking fresh root will be avoided. If this trial succeeds, it will be the greatest inducement that can be for the farmer to adopt the same method, since it will require only one ploughman, a woman to sow the beans after the plough, another to lay the sprouted madder in the furrow, and a person to cover the whole over with a rake.

"The gathering of the seed is expensive when one has but little of it, because, for fear of losing any of it, it is gathered almost seed by seed. I thought myself rich enough this year to try another way of doing this work. I caused all the tops to be cut off with a reaping hook; when there remained upon them but a few seeds that were not ripe, and the whole was then laid upon cloths in the sun. In two or three days the stalks and leaves became so brittle, that a few strokes of a switch reduced them into dust. Two turns of a winnow blew away their dust, and with it the unripe seed, which after they had been dried, were found to be lighter than the black or purple ones, in which the horny substance was formed. I hope next year to be in a condition to proceed with still less precaution, that is to say, to mow at once all the branches and stems, and then to separate the seeds from them in the same manner as before. It generally is during the whole of the month of September that the seed of madder is fit to be gathered.

"After the seed has been thus separated from the stalks, and winnowed clean, it must be exposed to the sun till it becomes perfectly dry; for if there remains the least moisture in the black pulp which surrounds it, a fermentation will ensue in the winter, or at least a mouldiness, which will destroy the germ. It must afterwards be put up in bags of thin cloth, and these should be hung to the ceiling of a dry and airy place, as well to preserve the seeds from all moisture, as from mice, which are very fond of them.

"If it be intended to sow wheat after the crop of madder, the roots of this last must be taken up in the beginning of October. It is not possible for me yet to point out a better method of doing this, than to begin at one end of the field, and trench the whole ground two or three feet deep, whilst women gather up the roots as the men pursue their digging. The ground is then so well prepared for wheat, without using any dung, that two-thirds, or at at most three-fourths, of the usual quantity of seed will be sufficient to sow it.

"The madder now taken up might become burthensome to the planter, if the consumer thereof should seek to take advantage of the ease with which it corrupts: for the husbandman would in such case be forced either to dry on kilns whatever he takes up in this season, or to sell it at whatever price the buyer should be pleased to offer. These inconveniences seemed to me the greatest obstacles to the progress of this branch of cultivation, because they necessarily required, in the common way of proceeding, either that kilns should be built for drying the madder, or that its roots should not be dug up till they were to be sold. I therefore tried, as follows, to remove these disadvantages. On the sixth of October, 1761, I dug in my garden a hole three feet deep, into which I threw thirty plants of madder, then filled up the hole, and let it remain thus exposed to the air and rain. I caused it to be opened on the 30th of last March, and found all the roots in good condition. It was filled up again till the 15th of September, when, upon its being opened anew, even the vermicular

cular roots, the broken ones, and those which had been separated from the plant, seemed to me as firm and as sound as when they were first put into it; but to be certain whether they had not suffered some alteration imperceptible to the eye, I have dyed with them, in comparison with roots which I took up on purpose, and I have not found any difference in the liquor, or in the brightness and fixation of the colour.

"The husbandman may therefore, in case of need, keep his crop of madder a year in a hole made in his farm-yard, or in a pit dug at the end of the field; only observing to lay it in alternate layers of roots and of earth. He will thus be enabled to wait till he finds a proper opportunity to sell, and the buyer will no longer have it in his power to tyrannize over him by taking advantage of his necessities. The dyer, who will know his own interest well enough to adopt my method of dying with fresh roots, may also keep them equally well in the same manner, in a hole in his cellar, from whence he will take, whenever he pleases, whatever quantity of them he has occasion to use.

"It may not be amiss to repeat here, that when these roots are used fresh they need only be washed a little to clear them of earth, and that the quantity of them put into the dye should be after the rate of four pounds for each pound of ground-madder, which the operation would require. These roots are cut into middle-sized pieces, and pounded in mortars of stone or wood (iron absolutely excepted) till they are reduced into a kind of punnise, and this is thrown into the copper when the water (of which I have experienced that, in large works it is hurtful afterwards to increase the quantity) is a little more than lukewarm. The liquor is then heated to a degree at which a man can hardly bear to hold his hand in it, and whilst it is in this state the stuff or cotton is pushed down into it, and there worked about during three quarters of an hour, between hot and boiling, after which the liquor is made to boil during three quarters of an hour more.

"As this liquor remains, after the dying is finished, much finer than that which has been made with the Dutch ground-madder, I intend this winter to try whether it may not be put to some farther uses; and I shall in due time give an account of whatever I may succeed in."

M. Duhamel thinks the month of September the most proper time for cutting the stems of madder, in order to their being made into hay. The Flemings cut theirs in August; but that is when they do not intend to save the seed, of which indeed their madder yields but little, as was before observed. As Mr. Ray informs us that the madder which grows wild in England preserves its verdure all the winter, it will become a considerable addition to our winter and spring succulent food for cattle, and this will add greatly to its value; for this plant has been experienced to be an excellent fodder for cattle.

Cows fed with the tops of madder yield plenty of milk, which is a little tinged with red; and the butter of it is yellow and well tasted.

After the madder has been cut for hay, the ground should be gently stirred, especially in the alleys, and particularly if these are to be planted with madder the next year.

When the same ground is to be planted anew with madder, the whole of it should be thoroughly ploughed after all the roots are taken up, and the beds should now be made where the alleys were before. If the ground is sown with wheat after this second crop of madder has been taken up, the farmer may reasonably expect an abundant crop of corn: for besides that madder does not impoverish the ground, the weedings and frequent stirrings necessary for the culture of the plant prepare it well for wheat or any other crop. M. Duhamel confirms this by the following experiments.

A field of madder being dug up, he sowed it with spelt, which was harrowed in, and did not appear for six weeks, because the ground was very dry: and even after this, only a small quantity of it sprouted: yet, at harvest, this field yielded as many sheaves as others in the same country; but with this essential difference, that the straw of these was six feet long instead of four, and the ears were as long again as those in the other fields.

Another year, having sown spring-wheat after a crop of madder, there were, at harvest, twenty dozen of sheaves on an arpent (about an acre and one fifth) whilst the other fields yielded but eight or nine. Likewise, another year again, having sown oats on a piece of ground where the

madder had just been dug up, it yielded forty dozen of sheaves to the arpent. The common lands produced that year but five or six dozen.

The peasants about Lisle, being in too great a hurry to enjoy the fruits of their labour, take up their madder before its roots have attained a proper size. The Zealanders let their's grow larger. A medium should however be observed; for the roots which have remained longer in the ground yield less dye than those which have stood only till they have acquired the bigness peculiar to each kind.

This root, which is one of the best ingredients that can be used for dying wools and stuffs, gives them a red colour, not very bright, it is true; but which resists, without alteration, the influence of the air, the heat of the sun, and the effects of the ingredients made use of to try colours: it contributes also to make other mixed colours lasting: finally, a method is found out of giving cotton a very pleasing and lasting carnation colour with it. All parts of the root do not yield this red; the dye of some parts fades, and other parts are worth nothing at all.

In examining a well conditioned root of madder with a microscope, under the outer bark, in the flesh may be perceived some red particles, which certainly yield the colour which the root contains; but there is, besides this, seen a great quantity of woody substance of a fallow colour; and this substance probably impairs the first mentioned colour. According to M. de Tourniere, this fallow colour is not so good a shade as the red; and he imagines that leys, &c. give a brightness to the colours dyed with madder in no other respect than by abstracting this fallow colour. The sun and dews have the same effect on yarn dyed with madder, when it is exposed on the grass.

M. de Tourniere also imagines, that the part which yields the red, is, in the green root, dissolved in a mucilaginous juice; for the bark, and the other parts which contain most red, are also most succulent: by drying them in a kiln they lose seven eighths of their weight, and yet the roots are not perfectly dry; for they bend before they break; they are rather bruised than ground by the mill; and this unctuous powder is apt to clot: it is true, that in time they lose this unctuousness, and become dry; but at the same time the quality of the red particles is lowered. These observations are well deserving of attention; for they make it evident to us, that these valuable particles may be impaired by too great a heat: supposing it unctuous, were it too much dried, perhaps water would not dissolve and separate its parts. Finally, these reflections of M. de Tourniere agree very well with the experiments of M. d'Ambourney, and convince us that madder-roots may be used green with very considerable advantage. But green madder can never be used, except when the grounds lie convenient for the dyers: thus, when madder is to be carried to any considerable distance, it must of course be dried, and pulverised. I shall resume this subject.

1. As madder roots are very apt to ferment when they are brought green, it will necessary to examine carefully whether they are spotted, or have a musty smell: if the fermentation has given them a black hue, they are by all means to be rejected.

2. The roots to yield a fine dye should be fresh: such as are dusty on being broke must therefore be rejected, and with still greater reason those that are rotten and worm-eaten: on the contrary, such ought to be preserved as have a strong smell somewhat like that of liquorice: the ground-madder should be unctuous, and run into clots on being handled.

3. As madder is sold by weight, it is an advantage to the purchaser to have the roots quite dry; but he should be careful that they have not been kiln-burnt: such as have a strong smell have seldom this defect. Too hasty a drying wrinkles and splits the bark: and, as it then separates very easily from the wood, the most useful part is lost: the bark therefore should be smooth, entire, and adhering to the wood: but we must not confound the true bark with the outer barks or epidermis, which would only lessen the brightness of the colour.

4. The largest roots are not always the best: they are frequently yellow, and have but little of that red which alone yields the colour. The very small roots are of little value, as they have too much outer bark, which hurts the colour: but those of the best quality are from the size of a goose-quill to that of the end of the little finger.

5. In breaking the roots there may be seen, as I have already

already observed, two substances differing one from the other : that which inclines to a yellow only, hurts the dye : that of the deep red is the part really useful ; consequently the highest coloured roots should be preferred.

It would be a useful discovery, could there be a method found out of extracting the red particles without any mixture with the fallow or yellow part : I am of opinion the trials should be made on the green root, that the red particles, which are then in a state of dissolution, may be more easily extracted.

6. As the surest method of knowing the quality of madder is to make a trial of it on some piece of stuff, it will not be amiss if such as plant much of it accustom themselves to make this trial, that they may demonstrate to the purchasers the quality of their roots : the following process for doing it, is extracted from the works of M. Hellot :

To dye a pound of wollen-yarn, a bath must be made with five ounces of alum, and one ounce of red tartar, dissolved in a sufficient quantity of water : the wool that is to be dyed must be well drenched in this liquor : in about a week half a pound of ground madder root is to be thrown into water as hot as you can bear your hand in it : and, after having mixed the water and powder together, with a stick, the wool is put into it ; and the bath must be kept hot for an hour, but not boil ; for, if it did, the colour would be dull : but towards the end of the time the bath is made to boil ; but the yarn must be instantly taken out.

As very trifling circumstances will affect the beauty of the colour, it will not be amiss to make at the same time two trials with the same yarn ; one with the madder that is to be proved, and the other with the fine madder of Zealand, or azala : the beauty of the skains will determine which is the best madder.

As these trials may as well be made on two or four ounces of yarn as a pound, the baths may be made accordingly. I shall now treat of the methods of dying and pulverising madder.

We have observed that green roots are very apt to ferment : it is therefore necessary to abstract the great quantity of moisture that causes it. If the weather is very dry and hot, it is certainly adviseable to take the advantage of it, to dry the roots in part, and save wood ; but, if the weather is damp, the root must be spread under sheds, or on barn-floors, and often moved : for, if they were laid in heaps, they would soon heat, and change, more or less, according to the state of fermentation they were in. With care the fermentation of the roots may be greatly lessened ; and, according to M. d'Ambourney's opinion, they may even be kept good for some time ; but the roots cannot by these means be made dry enough to preserve them from any change. For small crops a common oven will serve ; but it must not be heated to above forty-five or fifty degrees of M. de Reaumur's thermometer. But this method is very tedious ; it would require very large ovens to supply the place of kilns. To save the expence of building a kiln, I would recommend the making a place over the roof of the oven, to put the roots in, that they may begin to dry : but, if we grow much madder, it is absolutely necessary to have a kiln proportioned to the quantity that is to be dried, not only of our own crops, but to those peasants that cannot afford kilns.

The kilns may be made of very different forms, many of which are of equal goodness ; but when a man proposes building one, he should be attentive, 1. That it may contain a large quantity of roots : 2. That it may be worked with ease : 3. That as little fuel as possible may be used : 4. And that it be so contrived as to retain an equal and moderate heat. To make these matters easy to planters, we shall describe the kilns that have been long in use at Lille for drying madder-roots : we shall point out their defects, as well as the defects of two kilns that were successively built at Corbeil ; and, lastly, we shall mention the attempts we have made to improve and perfect them.

Description of the Lille Kiln.

This kiln differs very little from that used for drying malt. To have a general idea of it, we must suppose there is a large furnace, in which a great fire is made : this furnace is made under an arch ; the hot air and smoke pass through a funnel over the furnace, and spread themselves in a space in form of an inverted pyramid, the bottom of

which is covered with a perforated floor, on which the madder-roots are spread. This is the general form of the kiln ; but we shall give a description of it according to the figures in the plate, for the use of such as intend to build one.

Fig. 1. Plate XVIII. represents the section of a building containing a madder-kiln.

In this building may be seen a vault, K, K, a ground floor, L, L, and a first floor, G, G, over which we are to suppose a granary, H. The foundation of the brick-work of the kiln, is somewhat lower than the bottom of the vault ; the walls terminate in arches, at the bottom of the first story ; the side walls of the building serve as upright supporters ; and the arches of the kiln are sustained by jambs, which are put into the side-walls. All this will be better understood by explaining the letters of reference.

A, an ash-hole two feet wide, three feet and a half deep, and two feet three inches high. B, the furnace with an iron grating, *b b*, at bottom. C, a pricked line, which determines the height of the furnace door : this aperture is sixteen inches wide, and seventeen high. D, the chimney, B, the perforated funnel, which disperses the heat, by means of the holes, *i i i*. It is to be observed, that this chimney is entirely covered at the top, to prevent any thing falling into it. I I I, holes two inches square, by which the heat escapes ; they are placed chequerwise. F, an empty space, into which the heat goes out of the funnel before it reaches the upper story. G G, a floor set with square tiles, on which the roots are to be spread one foot and a half thick. These tiles are fifteen inches long, ten or eleven wide, and two thick : they are perforated with conic holes, as here represented. H H, tubes four inches wide, by which the superfluous smoke escapes, and through which fall the dusky particles that drop through the holes in tiles of the floor G. These tubes are stopped by a little iron door, which is opened when the heat is too great.

K, the vault in which the fuel is kept. L places where the undried madder is safely kept. M, iron joists two inches thick, traversed by bars which bear the tiles that compose the floor. N, iron branches fixed to the beam P, to support the floor G. P, the beam of the second story. Q, a casement or window, to be opened at the beginning of every drying, to let out the smoke. When the madder begins to dry, these casements are shut, to keep in the heat. There are also in the second flooring two trap-doors, which are open to let out the smoke and steam.

Fig. 2. represents the plan of the furnace. The three iron bars which cross it, are each two inches and a half broad, and six lines thick ; they are let into the wall three inches ; the bars of the grating are one inch square, and riveted to the other bars. In this plan are to be seen the tubes marked H, to shew that they run the whole depth of the furnace. These tubes are very necessary to convey into the kiln the heat from the body of the furnace.

Fig. 3. represents the plan of the tiled floor, G : it is sixteen feet square.

As the furnace we have described resembles that used for drying malt, we were willing to observe in what manner it was dried, and remarked, that they lay it about nine inches thick, and that it is very hot at the bottom. When M. de Reaumur's thermometer was applied, it rose upwards of twenty-two degrees above Zero ; but the upper part being influenced by the external air, heats but little : the steam that rises, being condensed by the cool air, is reduced to water, which occasions the upper part of the bed of malt to be always wet : for this reason it must be often turned. In this method, by being often wetted with the steam, the bed of malt is much retarded in its drying. We imagined this inconvenience might be removed, by preventing the external air from affecting the surface of the bed : and this would be effected by making a covering for it : and, if this covering could be fixed within a foot of the malt, another advantage, which we shall mention, would result.

It is well known in physics, that the vapours which arise from heated matter, have a great power of penetrating and heating the matter whence they proceeded, provided they are collected, and in some manner reverberated on the matter to be heated : it is on this principle the machine was constructed in which the bones of animals could be dissolved ; and we know, that in an equal degree

degree of heat water has eight hundred times more volatility than air; and vapours or steam contain a great deal of water.

This induced us to think, that it would be of great use to reverberate the steam on malt and madder-roots, by means of the covering above mentioned. M. Villot, brewer at Paris, who takes all opportunities of improving his beer, has made some experiments of this nature, and in part succeeded. It is only necessary then to contrive a method of putting this in execution in a large building, of which we shall in due time take notice.

One great defect of the Lisle kiln is, that the smoke, mixing with the roots, charges them with fuliginous matter, which probably hurts the colour, and is perhaps the cause of the difference betwixt the Levant madder and that of Lisle, these last being by no means fit for dying cotton, as done in the Levant; besides, in these kilns the workman cannot properly regulate his fire: these defects might be removed by making the middle close, and terminating it in a tube of cast or hammered iron, to carry off the smoke; the floor, supported by iron bars, might very well be dispensed with, and instead of it one of wood, lattice, wicker-ward, or iron wire, would do; for the funnel once properly secured, there will be no danger of fire. In order to enable every one to vary the construction of these kilns, we shall add some reflections and observations made with great care by M. de la Levrie, who superintended the building of the two kilns at Corbeil.

Remarks on the Kiln used at Lisle.

It will not be amiss to begin by relating the experiments made with two kilns, built one after the other at Corbeil, to dry madder, as thereby the advantages of that, herein after proposed, will be more evident.

The first of these kilns was twenty-one feet long, twelve wide, and ten feet high: within-side it was surrounded by three stages of hurdles, like shelves, four feet wide, and twenty inches one from the other: the first stage was five feet from the ground: on these stages the green madder was laid eight inches thick. In the upper floor was a trap-door, which opened to let out the steam of the root. The furnace, which was not without defect, went three feet within the kiln: it was supplied with fuel from without: within-side it was furnished with metal tubes, which passed through the fire: these tubes received at one end the outward air, which they discharged within, very hot, by an aperture two feet from the ground. The effect produced from this kiln was as follows: the three stages, being filled with roots, those on the upper stage became dry enough to send to the mill. It is true, they dried but slowly, because the steam, which proceeded, though in no great quantity, from the two lower stages, wetted the under part of the hurdles of the first stage, thereby retarding the work. The heat, which was not powerful enough to raise all the moisture of the madder-root on the lower stages in steam, made them sweat abundantly, so that the under parts of the hurdles were covered with drops of water as big as the finger's end, which fell from the second shelf on the first, where they wetted the root; and from the first shelf they fell to the ground. On the upper shelf were very few of these drops of water, except for a very small space of time after the kiln had fresh roots put into it, because at the upper part of the kiln the heat was powerful, and regularly dispersed, whilst at the bottom it was cold. At each stage was fixed one of M. de Reaumur's thermometers: after four days continual fire the lowest scarcely rose to eighteen degrees; the second, somewhat higher: and the uppermost never passed eighteen degrees, which is thought sufficient, when the drying is not retarded by any steam from below. When the dried root was carried to the mill, the root from the second stage, which had lost part of its moisture, was removed to the third, and that of the first stage, still wet, was laid on the second, the first stage being filled with fresh roots. The lowest thermometer then fell to fourteen degrees, and the uppermost to Zero: this induced them to dry all the roots that were at once put into the kiln, before they admitted any fresh; yet even in this method it was necessary to move the roots from the lower to the upper stages, where the last laying dried faster than the others. As this work was tedious and troublesome, it was

determined to take down this kiln and build a new one, now in use.

The second kiln is of the same length and breadth as the first; but the hurdles on which the madder is put are raised only six feet from the ground, and the apertures of the furnace, which supply the hot air, are level with the ground: they, besides, continued to avail themselves of the mistaken advantage of encreasing the furnace to contain more roots, by making, as in the first, three stages of shelves. The roots indeed dry in it faster, because the furnace yields more heat; but this heat is very unequally dispersed at the different heights, and in the different parts of the length of the kiln; because the same inconveniences still subsist, as they have made in it, like the other, three stages one above the other, and they have formed the kiln long, without letting the furnace extend through its whole length. They have besides placed the first stage too near the fire; but this may be remedied by taking it entirely away, and using only the uppermost stage, which is fifteen feet from the bottom of the kiln, and may extend over the whole of it: the heat will then be more regularly dispersed. The roots may be laid fifteen or eighteen inches thick, and may be much easier attended to than on the shelves, which occasion a great deal of trouble: there might also be two furnaces, one at each end of the kiln, and the tubes might be carried over the whole length of it.

From what has been said, we may conclude, that to dry a plant like this, which contains a great deal of moisture, no advantage can result from having a kiln with three stages, one hurting the other; since the heat tending always upwards, the roots must be moved higher, which cannot be done without trouble, loss of time, and expence; whereas, the same quantity may be dried in less time on a floor raised eighteen or twenty feet above the furnace.

It is certain that a peasant, who raises madder after a proper method, will always be a greater gainer than such as are obliged to hire day-labourers. But the peasant can not go to the expence either of a kiln, or a mill: it must be planters who raise large quantities of it, and can afford the expence, that have them: thus it is to be presumed, the peasants will be under the necessity either of selling their roots green to the dyers, or taking them up in the spring to dry them in the sun, or drying them in their ovens, when they have only a small quantity; or, finally, of carrying their roots to the kiln, as they do their grapes to the press.

The Lisle kiln, though built on a good principle, is too expensive for a young planter. There must be strong walls to support the arches, internal abutments, and bricks to build the arches with. In some provinces there is not a workman capable of turning an arch in brick-work. The floor requires many large iron bars. On the other hand, a kiln in the form of an oblong square, like that at Corbeil, will never heat equally in its whole extent, unless tubes be made to convey the smoke through various parts of the kiln, before it reaches the chimney, or there is a furnace at the end. All this is expensive, and subject to inconveniences.

Perhaps then a kiln somewhat resembling a malt-kiln would do; and this might any where be built at a small expence: such a kiln need not be above eighteen feet square, and eighteen or twenty-feet high from the ground to the floor. Underneath the floor should be a reversed pyramid somewhat obtuse at bottom, to receive the funnel and tubes that are to give the supply of hot air: this may be made with quarter-stuff covered with lath and plaster. This kiln does not require any large furnace. The new kiln at Corbeil is much larger, taken from the second stage to the bottom; yet has the heat been brought there to upwards of forty-five degrees. The floor of the kiln is to be made with joists eight inches by four, covered with laths, grating, or with hurdles as at Corbeil, where it has already lasted seven or eight years: there must be walls to support the roof and beams, and it should have two windows: there should be a plaster-floor eight or nine feet above the grating, with one or more trap-doors, as they let out the steam much better than the windows: lastly, the beams should be plastered. There is reason to think that such a kiln would cost little, and answer the intended purpose. It should have been observed, that over the grated floor should be had a large thin cloth, or rather a hair-cloth, rising round the edges, and fastened with nails:

this is particularly useful when small roots are dried, as it prevents their falling through. A foot above the roots may be put wooden traverses, over which may be laid straw-mats quilted on cloth: this will keep down the steam, and may be of great service, as has been already observed.

The Furnace of this Kiln.

The furnaces of the Lisle and Zeeland kilns are certainly neither of them proper for drying madder, any more than those of the malt-kilns: they have all the same defect, as they fill the kiln with smoke, which damages the roots. It was this inconvenience induced us to endeavour to contrive one that would give a great deal of heat without the above defect. This may be probably effected, by not letting the funnel be perforated, and carrying tubes from it which should run under the madder before the smoke was discharged; and by having other tubes run near the fire, to circulate in the kiln a warm air, which they should receive from without. We have made the trial of such a furnace, and confess it did not yield sufficient heat: the furnace should certainly have been made larger, but the expence is a continual objection, which, besides being considerable, is pure loss to one that makes experiments for the public good, without being in a situation of reaping any profit from them. We shall close then what we have to say on madder-kilns, by concluding, that malt-kilns seem well adapted to the purpose; but some method must be found to prevent the smoke damaging the roots.

Madder well dried and cleaned may be sold in that state to the dyers: but if it is to be pulverised, there will be occasion for a mill, which we shall now describe.

Description of a Mill, at Lisle in Flanders, for pulverising Madder.

Plate XIX. fig. 1. represents the part of a madder-mill; it is insulated, and covered only by a slight thatch. The figures 2, 3, 4, 5, and 6; are supplementary to the first: we must have recourse to them in our explanation of the parts of the mill; they are therefore distinguished by the same letters, and each piece is represented apart.

A is a lever, or pole, nine feet eight inches long, and six inches by four in magnitude. B, the axis of the wheel, six feet four inches six lines high, and nine or ten inches diameter. C, stays or knees, four feet six inches long, and four or five inches square. D, the cogged wheel, three feet one inch six lines semi-diameter, and furnished with fifty-seven cogs.

The fellies, or circumference of this wheel, must be eight inches by four large: they are secured by an iron hoop. The traverses are six inches by four thick, pinned and keyed. The cogs are made of apple-tree wood, and project three inches three lines: they are two inches and a half by two at their insertion, and two inches and a half by one at top: and beneath the wheel they are two inches long, and one and a half square: they act on the rounds of the trundle head about an inch and a half of their length. The pins that fasten them are also apple-tree wood.

E is a beam twelve inches square. F, the trundle head, thirteen inches semi-diameter, furnished with eighteen rounds, each a foot long, and two inches diameter; the ends of this trundle head are two inches and a half thick, and hooped with iron. There are also two iron bars pinned on to secure the joints of the wood.

G is another axle-tree, or turning beam, eighteen feet six inches six lines long, ten inches square near the trundle-head, and fourteen inches diameter in its octagonal part. H, lifters four inches nine lines long, five inches broad, two inches and a half thick. Hence it is apparent, that there are fifteen lifters inserted into the axle-tree, to serve five beetles; that is, three to each. For this reason the lifters, the catches, and the pestles, are distinguished by the same figure.

K, flyers four feet five inches long, and four inches square: they are loaded with lead at their ends. L, catches, which answers to the lifters, H: they project five inches nine lines, and are five inches broad, and two a half thick.

M, other catches inserted into the sides, or thickness of the beetles, N, and answer to the leavers. Q, N, beetles ten feet four inches long, and four inches square. They are round at the ends next the mortars, and shod

with an iron foot four inches diameter, which may be seen in figure 6. The beetles are numbered in this manner, 1, 4, 2, 5, 3, (fig. 1.) to shew the order in which they play when the machine is in motion. O, cross-bars six inches by four, which support the joints, P.

P, joints eight inches long, six wide, and four thick. An iron pin, keyed, passes through each joint, and supports a moveable lever, Q, which acts on the catch, M, when the pestle, N, is to be kept up. Q, levers, two feet three inches six lines long, three inches thick, by four wide.

R, keeps, six or eight inches wide, to prevent the beetles from being disordered. S, an upright post four inches square, in which the cross-bars and keeps are inserted. T, mortars cut in a single piece of wood sixteen inches square: they are eleven inches deep, and their greatest diameter is seven inches: the bottom is lined with lead three or four lines thick.

V, a trough to prevent waste, over which hangs a cloth, fastened above to the keep, whilst the mill is at work.

X, a beam twelve inches square; this beam, and that at the other end, marked E, rest on the timber work that supports the roof. The sockets and pivots may be so well comprehended by the plate, that letters of reference were thought unnecessary; the sockets are brass, the pivots steel.

We have purposely omitted giving the dimensions of every part to avoid confusion: but the machine may be easily constructed by attending to the description we have given, which is very exact.

But though the mill described above, is now actually employed in grinding or pulverising madder at Lisle; yet it labours under several imperfections which we shall endeavour to point out, and describe a mill constructed in a more perfect manner.

There will be, however, no occasion to describe the wheel-work of this mill, it being the same as that of Lisle: it will be sufficient to give the proportion of the parts which compose it. The pole, or lever, from the centre of the axis of the cogged wheel to the part where the links of the spring-tree bar are fastened, is nine feet long; the wheel is five feet semi-diameter, and has seventy-two cogs; the trundle head is ten inches semi-diameter to the centre of the rounds, and has twelve rounds; thus it makes six turns to one of the wheel. The horse, going three feet in a second, makes three rounds and a half in a minute, and the trundle-head twenty. The axle-tree having on its circumference three lifters to every beetle, each beetle makes six strokes in a minute, and the four two hundred and forty in the same space. The square part of the axle-tree, on which the trundle head is fixed, is made out of a piece of wood five inches semi-diameter; the other part of the axle-tree is larger, being seven inches semi-diameter. It is necessary it should be so large, that the tenons of the lifters may have a proper length and thickness: it is much better to be round than octagon, or any other faced form, as the mortises may be more regularly made. From the end of the lifters to the centre of the axle-tree is twelve inches; so that in their motion they form a circle two feet diameter: the upper face of these lifters is cut in a curve, the radii of which are tangents to the circumference of the above-mentioned circle; the largest of these tangents is twelve inches, and determines the greatest rise of the beetles. By the lifters being thus curved, the resistance is equal, at whatever height the beetles may be, as they are always in contact with the lifters at the same distance from their center of gravity. As there are on the length of the axle-tree twelve lifters in four parts, they form, one with the other, angles of thirty degrees, supposing them to be seen one behind the other, as inserted on the same plane; on this account, when the first beetle is raised to half its height, the second is about to rise; the first quitting the lifter, the third is on the point of rising, &c. We say, on the point, because we are to observe that the lifters go under the catches, or under that which supplies their place, five or six lines; and that the greatest tangent of the curve, being twelve inches, is less, by near seven lines, than the sixth part of the circumference of the circle, and give the first beetle time to quit the lifter before the third rises: this is necessary, that the power may never have more than two beetles to act upon.

The front of the frame-work is that side before which the axle-tree turns. The frame-work consists of two beams, ten feet long, and eight inches square; betwixt them, at each end, is a traverse quarter, six inches by four.

In the middle of the length and width of the beams, rise two uprights, which are mortised and pinned: they are twelve feet eight inches high without their tenons, fourteen inches wide, and six inches thick, supported by a brace mortised into the front at the height of two feet, at the back part four feet and a half. Betwixt these two uprights is the block on which the beetles fall: it is made of a piece of dry tough elm, four feet and a half long betwixt the upright, to which it is joined by a dove-tail two inches thick, and as much deep: it is twenty inches high, and eighteen broad: it rests the whole breadth of its ends on the edge of the beams, and betwixt them, on three pieces of wood, at equal distances, that lie on the brick-work, which supports the whole. The block is divided cross-ways, by a partition two inches thick, parallel with the uprights, and of the same breadth, fixed into the block by two tenons, and in a groove wide enough to receive its whole thickness; the same is observed in the back part of the first keep, which is fixed: the upper end is in like manner fixed to the upper keep: this partition divides the block cross-ways into two troughs, each twenty inches long, formed by two sloping planks; so that the troughs are four inches and a half wide at the bottom within, eleven inches and a half at the top, and twelve inches perpendicularly high: and to prevent the loss of the light dust that rises in the work, the space betwixt the edge of the trough and the first keep is boarded up; the boards at the back part, as well as the sides of the troughs there, are fastened with grooves and dove-tails in the uprights and partition; those before lift up in a groove like a sash, and are fastened by turn buckles; the fronts of the troughs take entirely off; the pulverised root is taken out with a wooden spoon, and a feather broom, and they let it fall on a shelf before, which has a ledge four inches high: the fronts of the troughs are then put on again, and are filled with branch-madder; the sliding shutters are pulled down, and the pestles are set at liberty to work, which had before been stopped whilst the troughs were emptied; this takes but little time in doing, and the mill continues going during the time they gather up the root, and bolt or sift it. There are two keeps, which serve to direct the beetles; the under part of the first is three feet, and the under part of the second ten feet: above the block they are three inches and a half thick; the first is made level in the front with the back of the groove, that the sliding shutters may rest on it when they are raised. Each keep consists of two parts; those at the back are let into the uprights and pinned to them, and strongly fastened to the partition; those in the front are made to take down, and put up, as occasion serves; they slide in the grooves of the uprights, and those that run along the middle of the partition: they have, besides, two pins, by which they are kept in their places.

The beetles are at the lower parts twelve inches wide, eighteen inches high, and four inches thick; so that their face or bottom contains forty-eight square inches: the upper part or stock of each pestle, is eight feet and a half long, four inches wide, and three thick; so that in the whole, they are ten feet long, without comprising the cutters, which are four inches long, and formed like a carpenter's chisel; the blades of them are two inches and a half wide, and the tongues three inches and a half long: there are seventeen to each beetle. There are no catches, because the lifters being in contact with their extremity, always at the same distance, five inches from the centre of gravity of the beetles, the resistance occasioned by the friction of the stocks in the keeps, would have been very considerable. To avoid this inconvenience, a mortise twenty-five inches long, and three inches wide, is made in the face of the stocks of the pestles, strengthened on the sides by cheeks two inches thick. The upper parts of these mortises are six feet above the block; that is, on a level with the centre of the axle-tree; this part is lined with a plate of copper, strongly screwed, well polished, and rounded at the edge, to facilitate the fall of the beetles. On the side of the beetle-stock, sixteen inches below the upper keep, are fixed catches a full inch thick, two inches high, and projecting four inches, to keep the beetles up while the troughs are emptying.

The levers, which serve for this purpose, are placed behind, and rest on shoulders fixed on a piece of wood, which bears by its two ends on two brackets, mortised and pinned into the two uprights, and supported by braces: these pieces are six inches square. The levers are made

of quarter-stuff, six inches and a half square, as well as the lifters of the axle-tree. The upper face of the shortest arm of the lever is rounded like the lifters, in a curve described by the original circle, the radius of which is the space from the middle of the catch to the centre of motion of the lever, which should be parallel to the bottom of the catch. The radius of this circle, as well as the greatest of the curve, should be fifteen inches; that the beetle, being raised thirteen or fourteen inches, may not slip off. That the levers may be stronger, the wood must not be cross-grained; and in the centre of motion, it should be traversed by a square iron bar projecting two inches on each side; these projections, being rounded into pivots, rest on the shoulders of brass sockets. A cord is fastened to the shortest arm, and the end of it is fastened occasionally to wooden pins at the back of the block, to keep the levers somewhat lower than the catches, whilst the beetles are at work. The longest arm lessens by degrees towards the end, till it is reduced to a square; at this part is fixed another cord, which is fastened to the same wooden pins, when the beetles are to be kept up. The above description, with figures on the copper-plate, will be sufficient for an ingenious mechanic to construct a mill of this kind, which will doubtless be of great advantage to this kingdom, as considerable quantities of madder are now planted, and some of it fit for use.

R E M A R K S.

The beetles of this mill weigh only one hundred pounds with their mounting; perhaps a few pounds more, which may be abstracted by taking off a few inches of the lower part: there are never more than two beetles raised at a time, and one hundred and thirty-three pounds and a half for the power to act upon. A middle sized horse is generally reckoned able to apply one hundred and eighty pounds of his strength to move a machine, working for four hours together, and going three thousand six hundred yards in an hour: he often goes faster, but so was this mill calculated: there remains then forty-six pounds and two thirds for the action, which is more than it amounts to in this machine: we may even venture to assert, that the friction of it is less than any other mill of the kind. A horse may bear this work the better, as every five or six minutes there are two or three minutes respite to empty the troughs and give them a fresh supply. This mill at Corbeil never pulverised above two hundred pounds of roots a day, because that was all the kiln could supply it with; but the time in which this work was done, induces us to think it could easily pulverise four hundred and eighty, or five hundred pounds. They say that the Lisle mill can pulverise five hundred pounds in twenty hours: we scarcely believe it, especially as we imagine it does not work in the night: thus we must suppose it really works only ten hours, like that at Corbeil. Be it as it may, the work of these mills should be calculated by the weight of their beetles, the number of blows they strike in a minute, and the superficies of their bases; that is, the Corbeil mill is to that of Lisle, as four hundred pounds, the weight of the four beetles multiplied by two hundred and forty, the number of blows they strike in a minute, and the product by one hundred and ninety-two, the superficies of the bases of the four beetles, is to three hundred and eighty-five, the weight of the five beetles, multiplied by one hundred forty-two and a half, the number of blows they strike in a minute, and the product by sixty-three, the superficies of the bases of the five beetles; or, after the numbers are reduced, is as sixteen to three; by which it appears, that if the Corbeil mill pulverises five hundred pounds in twelve hours, that of Lisle should pulverise no more than one hundred.

The indifference they discover in Flanders, with respect to the situation of the kilns and mills, is worthy of blame: they are, it is said, in separate buildings, which have no communication; nothing can be more inconvenient. It is well known at Corbeil, that the root, which they some time ago pulverised in a little hand mill, fixed in a barn, ten or eleven yards from the kiln, which had no influence to warm it, grew damp, and clogged under the cutters, by which it was much damaged. This work is always done in winter, and it is scarcely possible it should be otherwise: the fogs must therefore be guarded against.

The kiln we have recommended would contain four thousand pounds weight of green madder, which would yield

yield five hundred pounds of dry root when it had been there forty-eight hours: the mill can pulverise this quantity in a day. If one had a very considerable crop, for instance, four hundred thousand pounds, which would yield fifty thousand pounds of dry root, and this is as much as the mill could turn out in four winter months, working every day, it would be necessary to have two kilns. The buildings to contain the kilns and mill might be disposed nearly in the following manner: A building should be erected sixty-three feet long, and twenty-one wide, with a floor twenty or twenty-two feet from the ground, which should be a store room for part of the green root: the under should be occupied by the mill and its frame-work, so that at each end there would be a space of eighteen feet to the walls at the extremities: in the middle of this space the apertures of the furnaces to heat the stoves should be made, which should be so situated that the floors of the kilns should be on a level with that of the store-room: trap-doors might be contrived in the floor of the store-room, to throw the dried roots down; and as they ought to be kept dry till they go to the mill, they may be heaped round the furnace under the reversed pyramids of kilns; for they should be kept dry till they are barrelled up.

On a supposition that the produce of four hundred thousand pounds might be pulverised in the four winter months, some place should be provided to keep it in proper order till the last went to the kiln: it must be spread at most two feet thick, that it may every day be turned. Experience convinces us, that eight cubic feet of green root weigh one hundred pounds. The surface of the granary will give one thousand three hundred and twenty-three square feet, which, divided by four, give three hundred and thirty quintals and a quarter, or thirty-three thousand seventy-five pounds; but this does not come near four hundred thousand pounds. It is presumed, the best would be to erect some large building, four or five stories high, which might altogether contain, at least, twelve times as much as the store-room above-mentioned: but this expence might be saved, if the root could be taken up in small quantities during the autumn, winter, and part of the spring.

Explanation of the Figures at Corbeil Mill.

Fig. 4. Plate XVIII. is the frame-work of the mill seen in the front: fig. 3. is the same frame-work seen endwise, the upright and beam being taken off.

A, beams, eight inches square, seen endwise (fig. 4.) and the length of one of them, which is ten feet (fig. 5.) B, traverse quarters, which are fixed into the beams; the length of one of them is seen (fig. 4.) and the ends of both are seen (fig. 5.) they are six inches by four.

C, a flooring or stage laid on the grooved edge of the beams, and the traverse quarter.

D, uprights fixed to the beams: their thickness may be seen (fig. 4.) the top of one of the uprights only is perceivable (fig. 5.) over the upper keep, N; and the breadth of the bottom is distinguished by two pricked lines on the end of the block which covers it, as the remainder of it is concealed by the middle partition. These uprights are twelve feet eight inches high, six inches thick, fourteen inches broad, as high as the axle-tree, then reduced to ten inches.

E, braces which keep the uprights steady on the beams; those in the front are mortised at the height of two feet, those behind at four and a half: they are six inches by four.

F, the block on which the beetles fall; it is made of elm, four feet and a half long betwixt the uprights, and twenty inches high by eighteen broad: it has at each end a dove-tail two inches thick, and as much deep, which goes into the grooves of the uprights.

G, a shelf, level with the upper part of the block, of the same length, twelve inches wide, two inches thick, and a ledge four inches high: it rests on a groove at the edge of the block, and on the brackets H, fig. 4 and 5.

I, three pieces of wood, which support the block.

K, the brick-work, which is the foundation of the frame-work.

L, a partition which divides the block into two parts: it reaches from the block to the upper keep; it is two inches thick, and the same breadth and shape as the uprights; it has on the front, and two sides next the uprights, grooves which run up till it begins to narrow; there are other similar grooves in the uprights. This par-

tion consists of two parts; the lower part is fixed in a groove of the block, and above with a tenon, and is besides pinned to the back part of the first keep, which is fixed: the upper part is tenoned into the upper part of the keep, and the under part of the second: they go into grooves that cross the whole breadth of the front parts of the keeps, which are moveable.

M, troughs in which the roots are kept: they are four inches and a half wide at bottom, eleven inches and a half at top, and twelve inches perpendicularly: they consist of two boards sloping before and behind (fig. 5.); the space between their edges and the first keep is boarded up. In the front *d*, are sliding shutters. The front of the troughs take off. In fig. 4. is seen one of the troughs open, and the sliding shutter pushed up: two of the beetles are also visible; one quite, the other half raised.

N, are keeps, three inches and a half: their breadth consists of two parts: those behind are entirely fixed to the uprights: they are seven inches broad, notched half the thickness of the stock of the beetles, in the parts where they pass: the other two pieces take off at pleasure, and are notched in the same manner, to give the beetles room to work: they have each of them two keys, or tongues, four inches broad, four long, and one thick, which go into mortises in the fixed part of the keep, between the stocks of the two beetles belonging to each trough, where they are fastened by two large pins, *g*. They slide on the grooves of the uprights: the undermost is six inches broad, that the shutters may slide over it: the uppermost is four inches, consequently it projects an inch: the edges are rounded off. The under part of the first keep is three feet above the block; the under part of the second, ten feet.

O, beetles ten feet high: they are twelve inches broad at bottom, to the height of eighteen inches (fig. 4.) four inches thick (fig. 5.) with a stock eight inches and a half long, and four inches broad, by three thick. At an inch above the first keep, they are left seven inches broad, for thirty-seven or forty-eight inches, to make room for a large mortise, *b*, twenty-four inches long, and three inches wide. The upper part of the mortise is lined with copper, the angle being rounded off. Sixteen inches below the second keep, there are on the sides of the stocks catches, *i*, two inches high, an inch thick, and projecting four inches. The bottoms of the beetles are secured with an iron band, *m*, one inch and a half broad, and four lines thick, and armed with seventeen cutters, *n*. The order in which they are placed may be seen in fig. 7. and the shape of them in fig. 8.

P, (fig. 4.) is a bracket six inches square with its brace, both mortised and pinned into the upright (fig. 5.). There is another on the other upright, not visible in fig. 4.

Q, (fig. 4.) a piece six inches square, fixed to the brackets. The end of it might have been seen in fig. 5. but it was not pointed out, to avoid confusion.

R, shoulders, resting on, and pinned to the piece Q, notched at *o*, to receive the leaves, fig. 4; also at *p*, fig. 5. to receive their pivots.

S, levers which serve to raise the beetles, and keep them up while the troughs are emptied: they rest on shoulders, R, where they play: they are made of a piece of even grained wood six inches broad, and two inches and a half thick: the length of the shortest arm is fifteen inches; that of the longest sixty inches. The center of the point should be on a level with the under part of the catches. At the extremity of the long arm is fastened a cord, *g*, which is fixed to the pins, *r*, in the block, when the beetles are raised thirteen or fourteen inches. Another cord, *s*, is fastened as near as possible to the end of the short arm, which is tied to the same pins *r*, when the beetles are at work.

T, the turning axle-tree, seen endways, fig. 5. and in front, fig. 6. It is round, and fourteen inches diameter. It is furnished with twelve lifters, on four planes, so disposed, that, when it is at work, the lifters answer the mortises, *b*, fig. 4. by which they raise the beetles, without touching the sides: they may all be seen in fig. 5. Those that are on the same plane, are distinguished by the same figures, 1, 2, 3, 4, as well as here in fig. 6. They are made out of pieces of wood, six inches broad, and two inches and a half thick: their tenons, X, fig. 5. are two inches and a half by two, and as long as possible, without touching in the center of the axle-tree. From the center of the axle-tree, to the point of contact of the levers

levers with the mortises, *b*, is twelve inches : this point is five or six inches under the mortises. Great care must be taken, that the tenons of the lifters be not made of cross-grained wood.

V, V, (fig. 7.) the base of a beetle, to explain the manner of placing the cutters, which are represented by black lines, as if only their edges were seen. The prickled lines make the division of the superficies to arrange them.

Y, (fig. 8.) one of the cutters, marked *n*, fig. 4, and 5. The height from the upper part of the shoulder to the edge is four inches ; the tongue three inches and a half ; its largest part half an inch square ; the shoulder about eighteen lines diameter : the edges twenty-seven lines broad ; they should be steeled and short.

The fig. 7. and 8. are drawn by a scale, four times as large as the rest, that their parts might be the better distinguished.

MADS, earth-worms.

MAGGOTS. See SHEEP.

MAIZE, a species of grain so generally used for food in America, that it has obtained the name of Indian corn.

The size of its ears differs, greatly according to the fertility of the soil, and the warmth of the climate in which it is cultivated ; but, at a medium, it is about a span long, and commonly has eight or more rows of grain, each of which usually contains upwards of thirty seeds, of various colours, as red, white, yellow, blue, olive, greenish, blackish, speckled, striped, &c. sometimes in the same field, and the same ear : but the white and yellow are the most common : nor does this diversity of colours ever reach beyond the outside of the grain, the flour of which is always white, with a little tinge of yellow. These seeds, which are as big as large peas, are round at the outer surface, very smooth, and set extremely close, in straight lines. The ear is clothed and armed with several strong thick husks, which defend it not only from unseasonable rains, and the cold of the night ; for it does not ripen fully in some places, till towards the latter end of September ; but also from crows and other birds, which being allured by the sweetness of the grain before it hardens, flock to it in great numbers, suck through the top of the outer covering, and devour as far as they can reach. In the northern colonies, the stalk of this plant, which contain a remarkably sweet pith, and is jointed like a cane, does not grow near so high as in the southern parts. It has long leaves, almost like flags, at every joint, and at the top a bunch of flowers, of various colours, highly pleasing to the eye. The northern Indians, far up in the country, have a species of this grain, called Mohawk's corn, which never grows high, and, though planted in June, ripens in due season. The general time of planting it, is between the middle of March and the beginning of June, or more particularly, from the middle of April to the middle of May.

Mr. Ray was of opinion, that there are only two really distinct species of this plant ; but Mr. Miller is certain there are three, which do not alter by culture, and he enumerates them in the following manner :

"The first of these, with yellow grains, grows naturally in the islands of the West-Indies, and has a very large, strong stalk, which rises to the height of ten or twelve feet. Its leaves have a broad white mid-rib, are long, broad, and hang downward. The male flowers (for maize has both male and female flowers, situated at remote distances on the same plants) come out in branching spikes at the upper part of the stalks, and are from eight to ten inches long. The female flowers come out from the bottom of the leaves on the side of the stalk, and are disposed in a close, long, thick spike, which is covered closely with their leaves : out of the end of this cover hangs a thin long bunch of filaments or threads, which are supposed to convey the *farina fecundans* of the male flowers to the germ of the female. When the seeds of this sort are ripe, the spikes or ears are nine or ten inches long, and sometimes a foot : but these rarely ripen in England.

"The second sort, which has white grains, is cultivated in Italy, Spain, and Portugal. The stalks of this species are slenderer than those of the former, and seldom rise more than six or seven feet high. Its leaves are likewise narrower, are hollowed like the keel of a boat, and their tops hang downward. The spikes of the male flowers of this are shorter than those of the former sort, and the ears or spikes of grain are slenderer, and not more than six or seven

inches long. The grains of this sort do not come to maturity in England, unless the season proves very warm, and they are planted early in a warm soil and situation.

"The third species, which has a yellow and white spike, is cultivated in the northern parts of America, and also in Germany. The stalks of this are slender, and seldom rise more than four feet high. Its leaves are shorter and narrower than those of the two former, are hollowed like the keel of a boat, and their tops hang-down. The spikes of the male flowers of this sort are shorter than those of the others, and the ears, or spikes of grain, are seldom more than four or five inches long. This sort ripens perfectly well in England, in as little time as barley, and therefore may be cultivated here to advantage."

This plant is seldom cultivated in England for use, though it might probably turn to good account, as was lately experienced by a gentleman in Lincolnshire, who planted this corn in an open field, where it ripened perfectly, and yielded an abundant crop ; but very great quantities of it are raised in Asia and Africa, in several parts of France, in Italy, Germany, and North America : its culture in the latter is given in the following manner, by a very worthy and ingenious gentleman of that country, who speaks from his own knowledge :

"The English in North America plough the ground thoroughly before the grain is planted. They seldom, if ever, dung the whole face of the field, but sometimes put a little dung in each hill of corn, if they think the ground requires it. Where fish are plenty, in the planting season, they put two or three small fish into each hill, with the grain.

"In order to plant the corn, they make trenches, or furrows, with a plough, cross these with others of the same distance, which divide the field into squares ; and where the trenches intersect, the grain is put in and covered. Three or four grains are commonly planted for each hill. The intermediate ground is afterwards ploughed at leisure, as the plants grow, and want more loose earth for the roots to spread in. The hills are made at the time of weeding ; some loose earth being then hoed up over the roots, and round the stems or stalks of the corn.

"The corn is planted at different distances in different places. In the northern colonies, the Indian corn grows low, seldom exceeding four or five feet in height ; and the leaves being proportionably small, the plants do not require so much ground as in the southern colonies, where they frequently rise to fourteen or fifteen feet. The space generally allowed for the lowest plants, is three feet, and for the highest five or six. This distance may be more necessary in our manner of cultivating this corn, more ground being required to nourish three or four plants than one ; for I do not know that we ever pluck up any of the plants. An advantage attending this method is, that the labour is less in hilling ; three or four plants being earthed up in the same time as one ; and there is more room for passing between the rows when the corn is to be weeded.

"At the same time that the corn is weeded, the ground is loosened round the plants with a hoe, and the hills are raised and enlarged from time to time, by adding more earth. The morning, before the dew is off, and the evening, are reckoned better for this work than the middle of the day.

"The hilling of the corn, as it grows, has been the universal practice ; the design being to give the plant more nourishment, and to support it better against the winds : but of late, some planters have thought it better to plant in holes : the reason is, that this plant requires a good deal of moisture ; and indeed nature, by the form and position of the leaf, appears to have intended the receiving of the rain that falls around, and conducting it to the stalk, and by that down to the roots : but a hill round the stalk tends to throw the water off to a greater distance ; and as to supporting the plants, they say the hills do not effect it, because, by covering the stalks in that part from the air and sun, which would harden them and strengthen them, the mould around them keeps them soft and tender, and thereby rather weakens them.

"The panicles, or tassels, contain the *farina fecundans* of the plant, and therefore should not be cut off till the grain in the ear is filled. If the tassels of a whole field should be cut off before that time, there would be no grain at all in the ears. This has been proved by experiment.

"In

"In the more southern colonies, where hay is scarce, and the leaves of this corn are very large, they cut them off for fodder: but in the northern colonies, where there is plenty of hay, and the leaves of the corn are small, they generally neglect cutting off the tassels, and stripping off the leaves. They are left on the stalks, and the cattle, being turned into the fields, after the corn is gathered in, eat what they like of them: but they are not esteemed so good as what has been cut in season.

"An easy way of taking the grain out of the ears is to rub them against each other, holding one in each hand.

"When the ears are stript of their husks, they are reckoned in the best state of preservation: much better than when the grain is rubbed off from the ear: for then, they say, insects can get at the soft part of the grain, and eat into it, which they cannot do while the soft part is connected with the cob in the ear, and the hard flinty part of every grain is turned outward, and the grains close to each other.

"To preserve this corn, they make in North-America a sort of bins, or cages, which they call corn-cribs, fifteen or sixteen feet long, and five or six wide, widening upwards to the top a foot or more. They are made of sapling poles, three or four inches diameter, framed roughly together, by notching the ends where they cross the corners, at such a distance from each other, as but just to keep the ears from falling through, that there may be a free passage for the air. These bins stand abroad, and have a slight moveable covering, or thatch to keep out the rain. The Indians bury their corn in holes in the ground, lined with mats and dry leaves.

The manner of using this corn in America, is various. It has this advantage over wheat, that subsistence may be drawn from your corn-fields long before the general harvest: for the green ears roasted, are delicate food; and as the corn ripens and grows harder, the ears boiled are good eating, with butter and salt. When it is ripe, the corn parched and ground into meal, is the hunting and war provisions of the Indians, being light to carry, and affording good nourishment. They mix a little of it with water, and it needs no other cooking, having already passed the fire in the parching. The grain soaked in water, will part with its skin when beat in a large mortar with a wooden pestle: then it is boiled, and eaten with milk. Being pounded coarsely, dry, it is also boiled, and eaten as rice. Bag puddings and baked puddings made of it properly, are very good. The meal is also boiled with water, to make what they call a hasty pudding, which they eat with butter and sugar, or with milk. This hasty pudding, or boiled meal, being mixed with twice as much dry wheat flour, and worked into loaves, makes much better and pleasanter bread than flour alone. All creatures fed with Indian corn have firm and fat flesh: the pork of corn-fed hogs is reckoned the finest in the world for taste and goodness; their fat is milk-white, and as hard as butter. The horses of Virginia and Maryland, whose chief fodder is the leaves and stalks of this corn, are reckoned the hardiest of the species, bearing most labour, and requiring least care, and the people of those countries where it is the common food of men, are healthy, strong, and hardy."

This corn is thought to keep better than wheat, and has frequently been of infinite service in many countries in times of scarcity of other grain; it answers all the purposes of the white pea, of about the size of which its grains are, and would certainly be a better substitute for the poor than bean-flour, or some other sorts, which have been used even in England, where maize may doubtless be cultivated to advantage in light sandy lands, in which beans and peas do not thrive well. It is excellent for feeding poultry, either given whole to the larger sort of fowls, or broken a little for the smaller. The Breseians, in particular, who are remarkable for the fatness of their capons, use a great deal of it for this purpose. The Indians reckon it a good remedy in all acute disorders; and it has been observed, that those people are very little subject to the stone, which some ascribe to their living upon this corn. They extract from its stalks, when green, a sweet syrup, which answers all the ends of sugar; and when the stems are divested of their ears, and dried, they make excellent fences, coverings of sheds, &c.

The Indians, and some English, particularly where the ground is good, and has been well manured with fish,

plant with the maize, in every corn-hill, a kind of French beans, which run up the stem of the corn; and are supported by it: others plant potatoes, gourds, or pumpkins, and others again sow turnips; in the intermediate spaces between the hills.

Some curious persons, by way of experiment, have planted seeds of only one colour in the same field; without any other coloured seeds near them; and their produce has been entirely of the same colour: but when the rows have been planted alternately with grains of different colours, they have interchanged, and produced a mixture of all the sorts in the same row, and frequently, as was said before, on one and the same spike. It is even affirmed, that they will mix with each other at the distance of four or five rods, if no tall fence or building stands between; so as to intercept their communication.

Mr. Miller, who mentions this, very rightly recommends the horse-hoeing husbandry; as, in all respects fittest for the culture of maize; and gives the following as a method in which it has succeeded beyond expectation:

The land, which was very light and sandy, and far from being rich, was ploughed deep before winter, and laid up in high ridges till the spring, when it was broken fine with the harrow. It was ploughed again in April, laid level, harrowed smooth, and then sowed in drills four feet asunder, into which the seeds were dropped at the distance of about eight or nine inches from each other. When the plants were about three inches high, they were thinned with a hand-hoe, by cutting up some of them where they grew too close, and the intervals between the rows were ploughed shallow, to destroy the young weeds: but when the stems were advanced, the ground in the intervals was ploughed deep, and the earth laid up to the plants on both sides; and when the weeds began to grow again, a third ploughing was given, to destroy them. This kept the ground pretty clean from weeds till the corn was ripe; as the season did not prove wet; for otherwise a fourth ploughing would have been necessary. Each of the stalks of these plants produced from three to six spikes of grain.

Sir Richard Bulkeley, who planted some of this corn in Ireland, from seed which grew in Brandenburg, had, from each of his grains, which were set a foot asunder in rows about a yard distant from each other, from three to six stems, and upon each stem three spikes or ears of corn, with two hundred and forty grains in each spike. An amazing increase!

Some good husbandmen in France have cultivated this grain upon nearly the same principles as those which Mr. Miller points out: The little differences in their methods may not be uninteresting: for which reason we shall here give the substance of M. Duhamel's account of their management of this corn:

"Maize thrives better in a light and sandy soil, than in stiff and clayey land. It cannot do without dung; and the ground intended for it should receive two good ploughings in March. A third ploughing, which is given towards the end of April, makes the furrows for the seed; and what clods remain after this, are broken by hand, furrows then preventing the use of a harrow.

"A fine clear day is chosen in May, to sow the seed, which is done by making at the bottom of the furrows, with a stick or other instrument, small holes, into each of which two grains of maize are dropped. The furrows are a foot and a half asunder; and the holes at the same distance from each other, are disposed in such manner that they form a kind of quincunx.

"When the corn is risen, the weakest of the two plants is plucked up, where both seeds have sprung; and where neither of them had grown, two new grains are planted.

"Towards the middle of June, the ground is hand-hoed round each plant; and as they stand in the bottom of a furrow, the mould which crumbles down, from time to time, lays fresh earth to their roots, and helps to support them. About the end of July, a slight hoeing is given them, which is the last; and in so doing the earth is laid towards the roots of the plants.

"The panicles of the male flowers, which grow at the top of each plant, and are well known not to contain any grain, are cut off about the middle of August. But care must be taken that the grain be impregnated before they are cut off; which may be known by the then turgid appearance

pearance of the outward covering of the ears : nor should the panicles be cut off from all the plants at the same time ; because some of the ears are not impregnated till a fortnight after others. These panicles are excellent food for cattle. When they are cut, or shortly after, all the leaves are stripped off the stalks, together with all the blighted and smutty ears : for it is said that the good ears would not grow so large, nor the grains be so well nourished, if they should be left upon the stalks. All these leaves and ears are given as fodder to oxen ; and it is remarkable, that those creatures are fonder of the smutty ears than of all the rest.

" The time for reaping maize is towards the end of September. The ears are then gathered by hand, and put into baskets, in which they are carried and laid in heaps from space to space in the field ; after which they are loaded in carts, carried home, and spread upon an even floor prepared for that purpose. They are then taken out of their sheath or hood, and dried in the sun before they are laid up in the granary ; or else the grain is taken out at that time. Maize which has been well dried in the sun will keep several years, and not be the less fit for sowing. The granary should be very dry, and the corn laid up in it should be turned at least every three months, to prevent its growing musty, or being attacked by insects.

" There are two ways of taking out the grain. The first, which is the most expeditious, is by threshing it with a flail : but in this method a great deal of the corn is broken or bruised. The second, and more common, is by rubbing the ears hard against the edge of a flat piece of iron. This easily separates the grains from the spike, or cob, without hurting them, and this remainder of the ear is very good food for oxen.

" As soon as the ears are gathered, the stalks remaining in the ground are plucked up, and laid by for winter fodder, for oxen. The field is afterwards ploughed up as soon as possible ; it being the general opinion of farmers, that the roots of the maize would otherwise continue to suck up the rich particles of the earth. Whether this be true, or not, their notion is, that if this ploughing should be deferred, the next year's crop would certainly suffer by it.

" When maize is planted only for fodder, particularly of cows and oxen, it is sowed very thick, and harrowed in, or covered with a rake, in a good soil, which has been ploughed twice, and well dunged : but it is observed, that in these thick sowings, all the female flowers are barren, and produce no grain : and it likewise is so great an impoverisher of land, that though the ground be dunged every time it is planted, wheat never does so well where this corn has grown, as in the neighbouring fields where it never was."

M. Aimen, M. D. in the province of Guyenne, where great quantities of this corn are raised, observes to M. Duhamel, 1. That it is important to sow maize rather in the beginning than at the latter end of May ; because, if it is sowed early, the plants will have acquired sufficient strength before the great heats, to shoot out then with vigour : nor will their ears be burnt, or liable to that barrenness to which they are subject when this corn is sowed late ; besides which, the stalks will be stronger, and their ears larger, and fuller of grain. 2. That the ears of maize are greatly hurt by cutting the panicles too late ; and that they ought to be cut before the hoods are open. By leaving a plant with its male flowers at every twenty feet distance, all the female ears will be impregnated.

In two different, but successive years, this gentleman singled out two rows of maize, the plants of which seemed to him equally strong. He cut off the panicles of the male flowers of all the plants in the first row, before their hoods opened, and let the panicles of the other row remain till the usual time of performing this operation : the consequence was, that the female ears of the first row were much the largest, and the best filled with grain.

He likewise sowed a row of maize at a distance from any other field planted with that corn, and cut off the panicles of that row before the hoods were opened ; leaving only one plant with its male flowers at every twenty feet distance. At harvest he observed, 1. That all the female ears of all the plants were impregnated. 2. That the female ears of the plants which had lost their male panicles early, were thicker, longer, and fuller of corn than any others. 3. That the female ears of the plants whose

panicles had been cut late, were smaller and shorter ; and that in some parts of them the grains were abortive.

To satisfy himself whether it be best to sow maize thick, or thin, he planted three different spots of ground with this corn, on the third of April, 1753. The seed used for the first, where the grains were placed about a foot and a half asunder, according to the common practice of the country, in which experience had instructed the husbandman, weighed one ounce and one penny-weight : the second in which the grains were only a foot asunder, was sowed with two ounces and two penny-weights of seed : and the third, in which they were but six inches apart, was sowed with four ounces and a half. The first of these spots produced eighteen pounds and four ounces of grain : the second fifteen pounds seven ounces : and the third, eleven pounds two ounces. A manifest proof, as M. Duhamel observes, that some sorts of grain will not thrive unless they are sown very thin ; and that, for want of this precaution, a great deal of corn is often lost, and the crops are considerably diminished.

As maize is a large plant, and requires much nourishment, it would certainly be right to try the culture of it with the horse-hoe : to this end, it will be proper to plant the rows two feet asunder, and the grains in them twelve or fourteen inches apart. All the necessary hoeings may then be given with the cultivator drawn by one horse ; and I believe, with Mr. Miller, M. Aimen, and M. Duhamel, that the corn will thrive the better for it, and the land be afterwards fitted for other grain. It is worth the while of those who live in the countries where maize is cultivated, to try what will be the effect of this method.

MALANDERS, cracks in the bend of a horse's knee, that discharge a sharp indigested matter ; they are often the occasion of lameness, stiffness, and the horse's tumbling.

This distemper is cured by washing the parts with a lather of soap warmed, or old chamber-lye ; and then applying over the cracks a strong mercurial ointment spread on tow, with which they should be dressed, night and morning, till all the scabs fall off : if this should not succeed, anoint them night and morning with a little of the following, and apply the above ointment over it :

Take of Æthiops mineral half an ounce ; white vitriol one dram ; soft green soap six ounces : anoint with this often, but first clip away the hair, and clear the scabs. On their drying up, it may be proper to give a gentle purge or two ; or the nitre-balls may be taken advantageously for a fortnight or three weeks. *Bartlett's Farriery.*

MALT, is barley prepared, to fit it for making a potable liquor called beer, or ale, by stopping it short in the beginning of vegetation.

It is said, that the soil on which barley grows makes a considerable difference in the grain, and that the barley fittest for malt is that which grows on a rich, light, or gravelly soil, and which has been raised from seed brought from a farm yard of a different soil and situation. The fullest and largest grains of such a crop should be chosen for making malt. It should be heavy, and perfectly sound, and such as has not suffered any accident in the field. Its being a little heated in the mow, is by some reckoned an advantage, because the grain will be the more equally dried, and will consequently the more equally imbibe water. If it has been so much mow-burnt as to look blackish when broken at the root end, or, as Mr. Combrune says, if it has suffered a heat of 120 degrees, it is unfit to make good malt. It is also found by experience, that barley taken immediately from the field does not malt so kindly as that which has been some time in the house, or mow. Special care should be taken that it be free from the seeds of weeds ; for these, in the malting, are apt to give the grain a bad taste, which cannot be afterwards got rid of.

By germination, all the principles of barley are put in action. The heat which it undergoes in malting separates and divides its parts ; and the viscosity which it before possessed, is removed by the looser texture of its oils, and their intimate union with the salt, which gives

gives malt the sweetish taste that distinguishes it from barley.

In order to its being malted, the barley is put into a cistern lined with lead or stone, and covered with water about six inches deep above the barley, to give room for its swelling. All the good grain will sink in the water; but, after stirring it, the imperfect, or distempered grains, will rise to the surface. These should be skimmed off, and given to poultry, or hogs, for they will never make good malt. By the water's gaining admittance into the barley, a great quantity of the air is expelled; as appears from the number of bubbles which rise on the surface.

The barley is left in the water two or three days, more or less, in proportion to the heat of the weather and the dryness of the barley. A judgment is formed that grain is fully saturated with water, from its appearing turgid, and easily giving way to an iron rod dropped perpendicularly into it. Or, take a corn from the middle of the cistern, and hold it steadily, by the two ends, between the forefinger and thumb: press it gently, and if it continues firm when so pressed, and the skin does not break, it must soak longer: if it crushes together and feels mellow, and the skin crack, it is watered enough. Nicety in this is a material point, and can be learnt only by experience. If the grain should be suffered to remain too long in the water, it would begin to lose part of its sweetness. When it has been steeped sufficiently, the water is drawn off.

The water used for this purpose should be that of a clear running stream, or rain-water; or, if such cannot be had, pond-water, provided it be sweet and clean, will do very well; or pump-water, which should be rendered soft, if it be naturally hard. If the water made use of is any way tainted, it communicates to the malt a taste which it never loses. Mr. Combrune advises the adding of lime to the water in which the barley is steeped; but this seems to be improper, because it appears from Dr. Home's experiments that lime renders water hard.

From the cistern, the barley is laid in a regular heap, or couch, where it must remain thirty hours, or till it contracts a heat. It must then be worked in one or more heaps, and turned every four, six, or eight hours, according as the weather is cold or hot. When it begins to spire, it should be turned every three or four hours, according to the temperature of the air; and as it comes (for so its spiring is commonly termed) the heap must be spread thinner to cool it, lest it be heated too much, and the germination be carried on too fast, by which the oils would be too much consumed. The turning of it must be continued in proportion as it is more or less slow in growth, so that it may be brought tolerably dry to the skin. When the roots begin to deaden, the couch must be thickened again, and often turned, that the growth of the roots may not revive. At this time, the spire should be near piercing through the outer skin of the barley: for if it grows quite out, the strength of the malt will be too much consumed. After the malt is made thus far, the common practice is to lay it at once on the kiln: but the best way is to gather it all up in one heap, to let it lie in that state twelve hours, and then to turn it every fourth hour, during the space of twenty-four hours.

No person should be suffered to tread on the malt with their shoes, while it is on the floor; because many grains are inevitably bruised thereby, and these, vegetating no longer, afford the roots of the other grains a substance into which they extend their fibres, and are by that means entangled in bunches; and besides this, the bruised corn acquires a degree of putrefaction which taints the liquor made of the malt intermixed therewith. Equal care should also be taken, that the grain be not bruised by any other means.

Mr. Combrune thinks, that the time most proper for malting is when the temperature of the air is such that barley begins naturally to germinate, at which season the thermometer marks from between thirty-two feet to forty degrees. How far that time may be extended, experience alone can determine. The warmer the weather is, the greater must be the disadvantage under which the maltster labours; because the motion of the fluids is then so strong, that the process goes on too quick, and the finer parts are apt to fly off; the consequences of which is, that instead of a sweet, the malt inclines to a bitter taste, the oils being turned rancid. This is so universally experienced, that brewers carefully avoid purchasing what is termed latter made malt.

The grain thus prepared for drying is spread on the kiln; where, meeting with a heat greater than is suited to vegetation, its farther growth is stopped. It is spread on the kiln three or four inches thick, and turned every three or four hours. The laying of it thicker is attended with inconveniences, among which is particularly its being unequally dried; and therefore that should be avoided. The strength and duration of the fire is different, according as the malt is intended to be dried, pale, amber, or brown. The pale malt requires more leisure, and less fire, than the amber or brown.

Pale and amber malt are dried with coke or culm; which not emitting any smoke, give the malt a brighter colour; and do not communicate that bad relish which malt has when dried with wood, straw, &c. the smoke of which taints it. Coke is best, because its fire gives a steady and constant heat, whereby the malt is dried uniformly. If wood, or any vegetable fuel is used, it should be extremely well dried, in order that, being as free as possible from moisture, it may yield the less smoke.

The size of the malt-kiln is generally proportioned to the quantity of malt for which it is intended. Some build their kiln square, and others make it round; but this last is undoubtedly the best form, because the heat of the fire is more equally diffused therein, and the grain is of course more equally dried. Various substances have been made use of for covering the kiln, such as tiles, plates of tin; and wire: of these, the wire is to be preferred, because it does not contract so great a degree of heat as to parch the grain in contact with it: but, for this very reason, hair-cloth is preferable to any other covering; because when any part of the malt is in immediate contact with a substance much more solid than itself, and therefore capable of receiving a proportionably greater degree of heat, the malt in contact with that heated body is parched or burnt, by heat which is not equally diffused through the whole mass; which mass cannot therefore be all equally heated. The hair-cloth is spread upon small wooden rafters, and these are supported by bars of iron laid across the kiln.

An ingenious and attentive maltster marked the degree of heat in the malt whilst on the floor; and the result of his observations in this respect is as follows: During the first ten days that the malt was on the floor, the heat in it was between 50 and 60 degrees. During the next three or four days, the heat was increased from 60 to 65 and 67 degrees; and during the last days of its lying there, to 80, 84, and 87; which last was the degree of heat when the malt was put on the kiln. There cannot be any absolute rule as to the difference of heat during the different times in the process of malting, because it must be suited to the heat of the air: at least we have not yet sufficient data whereon to found such a calculation. The heat of the malt on the kiln when fit for pale malt was 120 degrees, and when it was fit for brown, the heat 147.

This intelligent artist's observation, that the malt was fit for what is called pale malt, when its heat was at 120 degrees, suggests a caution which should be more carefully attended to, namely, that whatever colour it be intended to give the malt, the heat at first should always be the same: thus, for example, malt which is dried to the degree of high brown, should first be rendered pale malt, then amber, and so on progressively; not by a sudden increase of the fire, but by a longer continuance thereof. In this manner the whole body of the grain is equally and gradually dried; whereas a strong and quicker fire would parch, or as it were singe the outside, while the internal parts remain moist; and as that moisture is afterwards evaporated, it must crack the surrounding hardened crust, whereby the grain is again damaged in another respect.

As soon as the malt is dry, it must be removed from the kiln, and spread thin, that it may cool to the temperature of the air. It cannot be supposed that any of its parts are capable of retaining the fire in such manner as not to suffer it to escape; though some have conceived that they do. In proportion as malts are dried, their particles are more or less separated, and coming in contact with water, they strongly attract from it particles which fill up their interstices. In mashing, this action between the malt and the water generates a small degree of heat, but no way durable; though from hence arose the opinion, that brown malt is full of fire.

Barley may, at a medium, be said to lose, by malting, one fourth part of its weight, including what is separated from it by the roots screened off; but this proportion varies, according as it is more or less dried.

The condition of the barley, as to its greenness or ripeness, at the time of its being gathered in, is clearly discernible when it is malted. If it was gathered green, it rather loses than gains in quantity; the malt becomes of a smaller body, appears shrivelled, and often is unkindly hard; whilst, on the contrary, that which was cut at full maturity increases in malting, appears plump, bright, and clear, if properly carried through the process, and, on being cracked, readily yields that fine mealy substance so much desired by the brewers.

Malt which has not had a sufficient time to shoot, so that its plume, or acrospire, as the adepts in malting call it, may have reached to the inward skin of the barley, remains charged with too large a quantity of its unattenuated oils. All those parts which have not been put in motion by the act of germination, will, when laid on the kiln to dry, be so hardened, as not to be soluble in water, and consequently will be lost to the strength of the drink.

When malt is suffered to grow too much, or until the spire has shot through the skin of the barley; though all that is left be malt, yet, as too large a portion of its oils will have been expended in vegetation, the malt will be greatly diminished in proportion to what it ought to have been, and what remains cannot be fit to brew drink for long keeping, because of the loss of the oils.

Malt which has been duly worked on the floor, will, if it has not been sufficiently dried on the kiln, be apt to germinate or sprout afresh; perhaps to conceive so great a heat as to take fire; and should it continue long with a moderate degree of heat, the least evil that can be expected, is, that it will grow mouldy and have an ill flavour.

Malt well worked, but over-dried, will be so hardened, or its saponaceous quality will be so destroyed, that it will not imbibe from the air that moisture which is necessary to mellow it, and render it fit for brewing: for when it has been previously softened by the moisture of the air, it mixes more easily and more intimately with the water, and by that means yields a more copious extract than it would otherwise do.

Malt just or but lately taken from the kiln, remains warm a considerable time. Until it becomes as cool as the surrounding air, it does not mellow by the addition of a due quantity of moisture from the air; and the wort made of such malt requires a much longer boiling before it breaks, than that which is made of malt some months old.

The practice of those maltsters who sprinkle water on malt newly taken from the kiln, to give it the appearance of having been made a proper time, or, to use their own expression to plump it, is highly blameable. It is, in fact, a downright fraud, practised chiefly because less grain then fills the bushel: but a farther evil is, that if it be not used speedily, it heats, soon grows mouldy, and suffers great damage.

Malt dried on a kiln not sufficiently heated must require a proportionably longer time for it to receive the due effect of the fire: for want of which it will be in the same state as malt not thoroughly dried. Or if the fire be too quick, or too fierce, instead of gently evaporating the water from the corn, it scorches the outward skin, and separates it from the body of the grain. The malt to which this happens is called brown malt; of which Mr. Combrune observes, that, by the internal expansion of its parts, it occupies a larger space than it ought to do. He adds, that if such a fire be continued, it changes some parts of the grain into so brittle a substance, that the malt is said to be glassy. The particles which are thus hardened will not dissolve, or but in small proportion; so that they frequently occasion an almost total want of extract, which, in the phrase of the art, is termed, setting the grist.

The goodness of malt may be known by the following marks: Bite a grain of it asunder, and if it tastes mellow and sweet, breaks soft, and is full of flour from one end to the other, it is good. If it has a round body; and upon putting some grains of it into water, they swim on the surface, it is good. Barley sinks in water, and malt that is not well made will do the same: but it is to be observed that this is not an invariable proof, because, if the malt be

broken, or in the least cracked, it will take in water, and sink. Malt that is rightly made will not be hard, but of so mellow a nature, that if drawn over an oak board, across the grain, it will leave a white line upon the board, like a mark of chalk. Its smell also may be consulted; for malt, though otherwise good; may have contracted an ill scent from the fuel, or from the water used in the steeping.

Before malt is ground, it should be freed from the tails and dust, which would otherwise heighten the colour of the wort, render the liquor muddy, and give it a bad taste, which could not afterwards be got rid of. The cylindrical sieve will be of excellent use for this purpose.

The malt must be broken, in order to its communicating its virtue to the water. If it be ground too small, its flour will mix too freely with the water, and cause the wort to run thick. Many are of opinion that the best way is only to crack it, so that none of the grains may come out whole: for the intent is, that the water should draw out an extract, but not be mixed with the mealy part, in the manner of a paste or gruel. Some think that malt is better ground by a stone mill, than by a steel one, because the former bruises it, and the latter only cuts the grains.

After the malt is ground, it should lie some time to mellow in a cool room where no sun comes. The time for this is different, according to its kind. Brown malt may be ground at from three to fourteen days before it is used, in order that the corn, which is rendered uncommonly hard by that degree of drying, may be gradually softened by the moisture in the air; by which means it will become the more soluble in water. The pale malts require only one or two days. After lying thus in the air, less mashing suffices; the strength of the malt is more perfectly extracted, and the beer will be considerably stronger than it would be with the same quantity of malt taken directly from the kiln. Care must be taken that it get no damage in lying.

Mr. Combrune observes, that malt imbibes moisture more readily by being ground and exposed for some time to the air, than it does when whole; and that as the dampness thus absorbed by the grain is in reality so much cold water, malt which has been long ground requires to be mashed with hotter water than it would otherwise be necessary to use. See the article BREWING.

The reader is obliged for the following useful observations on the art of making malt to a very ingenious gentleman, who has practised the art many years.

Experience, and a constant observation on effects and their causes, have, says he, made me master of some pieces of knowledge relative to this subject, which your farming readers may probably think worthy their attention: the result of this experience I shall lay before them.

The first thing I shall mention, with regard to malt, is the benefit of changing the water whilst it is steeping.

Some maltsters think this change of water no ways necessary; others, on the contrary, approve of it, but do it indiscriminately in the same proportion during the whole season. They are in both respects wrong; for the times when the water requires to be changed ofteneft are at the beginning and latter end of the season, in autumn and spring, when the weather is warm; for in the middle of the winter the weather is too cold to admit of the water being at all changed to any advantage. Suppose the barley to be left in steep forty-eight hours in the spring: if the weather is inclinable to be warm, the water may be in that space of time changed three times; in other cases twice may be enough; but the best rule to go by, is that which follows.

Every maltster must know, that in the autumn and spring, if barley is left too long on the steep in the same water, the water will grow slimy, and sometimes sour: now I would advise the maltster to watch the changes of the water, and when he finds that it is smooth and oily to the touch, and that it is inclinable either to smell, or taste sour, let him by all means have it instantly changed; but he must observe, if he regards his interest, a particular method even in doing this.

The usual way of changing the water is, first to draw off that in which the barley was steeping, and afterwards by pails full, or by pumping, fill the cistern again.

This

This I do not approve of, because the barley when the water is drawn off lies closer, and is apt, in a very short space of time, to heat : this is a great damage to the commodity, and, without precaution, a considerable loss ensues. Now my method has always been, first to get a hoghead of water in readiness near the cistern, which I cause to be thrown on the barley the instant the first water is drawn off; and as a hoghead of water is sufficient to wet eight bushels of barley, I add afterwards as many hogheads, save one, as my cistern will wet quarters. By these means I avoid the danger of the barley heating in the cistern.

The consequences of not changing the water whilst the barley is steeping, are often fatal to the malt.

I have already observed, that in the spring and autumn it is necessary to change the water often in which the barley is steeped : it should likewise be remembered, that in these seasons the making of malt, in all its parts, is a very critical business; particularly it is then necessary that the beds, or couches, should be frequently turned, or the malt will not come kindly : but the tap-root will be apt to shoot forth vigorously, starving the other roots, and preventing them from accompanying it in its growth : this must be checked, and the remedy is, to turn the couch often, spread it thin, and give it a sufficient quantity of air, at the same time keeping it cool and temperate. This will stop the progress of the first root, give the others time to sprout, and the barley will malt kindly and regularly.

A thin skinned fine-coated barley is best for making malt, and is not the worse for not being very full bodied; yet would I by no means recommend a lean, half-starved, unripe grain.

Barley, which has grown on lands highly manured, is not so good for making malt, as that which has been produced by land of a moderate richness without any manure : in fact, a luxuriant soil, whether naturally so, or enriched by art, is not, in general, best for yielding barley for the maltster's use.

For the reasons above mentioned, never chuse to buy barley from the farmers who have large crops, as it is mostly a full bodied grain they have to sell. I prefer, for malting, a grain which is the produce of the soil that is rather poor than rich, rather light than strong, and more inclined to a gravel than a clay.

This grain is clean coated, taper, and elegant in its form, is full of flour, almost transparent when watered, and will be sufficiently wetted in forty-eight hours.

This grain increases in the malting, fills the bushel well, and makes a fine, sweet, wholesome, clean, full-bodied malt, from which the best of beer may be brewed, either brown or pale, according as the malt has been dried higher or lower.

Now I have mentioned drying of malt, a few cautions on that head may not be amiss.

My practice has been to give my malt as much drying as I could on the floor : this is not only a great saving of fuel to me, but is also attended with several other advantages.

I find that my malt, by being thus gradually divested of its outward moisture, does not shrink so much when it comes to be laid on the kiln; of course it measures to more advantage : it is besides of a better quality, having acquired no foreign taste in drying.

It may very easily be observed, that if malt is laid very damp on the kiln, a thick mist, or smoky vapour, will immediately arise from the surface of it, which being repelled and condensed by the cold circumambient air, falls again on the malt, where, by the heat from the furnace, it is a second time rarefied, and ascends in clouds of steam.

This alternate rarefaction and condensation of the moisture is of great disservice to the malt, giving it often a disagreeable musty flavour, and making it besides more unfit for keeping.

Now, by my method of suffering the malt to receive a part of its drying on the floor, this inconvenience is, in a great measure, avoided; for the gross moisture is already evaporated before it is laid on the kiln, and that which remains creates no great degree of steam, provided the fire in the furnace is not at first made too fierce.

With this precaution I have often made pale malt as fine as I have any where seen, such as some gentlemen, who long dealt with me, frequently say, constantly praised. In drying this malt, I took care that there was, during the whole time it was on the kiln, but a very moderate, yet equal, fire in the furnace.

If I had an inclination to have any malt high dried (for

some like brown malt better than pale) when the moisture was nearly evaporated; I caused the fire to be gradually increased till it roared again in the furnace, taking care that the malt should be properly stirred, lest it proved kiln-burnt; and by this method I had a fine, sweet, brown malt, fit for making harvest beer, such as some farmers are very fond of brewing.

Many are of opinion, that brown malt, used in the same proportion with the pale, will make the strongest beer; but this is certainly a mistake; for I have often made the experiment with great precision, but could never find any material difference, and what difference there was at any time, seemed to me to be rather in favour of the pale than the brown malt : this may easily be accounted for, as the flour in the pale malt always remained sound and uninjured in the drying; whereas the brown malt would sometimes, notwithstanding all the care of the maltster, be injured or parched by the fire, and that part which was parched had of consequence lost its spirit and virtue.

I must, however, on this occasion, make one necessary remark, which is, that some pale malts are slack dried; these, I own, make a raw, unwholesome liquor, which will not keep well; but if the pale malt is gradually and slowly dried by an uniform gentle heat, it will certainly answer the character I have already given of it, and will, besides, (I have experience for my voucher) keep as well as any brown malt whatever.

Maltsters in general are too little nice in the barley they buy. I have already said something on this head, to which I shall add, that I would by no means have them ever bargain for mixed grain : what I mean by mixed grain, is barley grown on various soils and in different fields. There is a sure disappointment in buying such grain, as the kerns will spire at different times, and some of them not at all; so that, after the couch is dried, some part of it will not be half malted, and a great deal of the remainder not malted at all.

In order to avoid this misfortune, for such it is, as the maltster's customers will, with too much reason, find fault with his commodity, let him by no means attempt to buy the barley, for that he is sure is mixed : I experienced myself, many years ago, a great loss by a purchase of the kind. A neighbouring farmer, with whom I was well acquainted, brought a sample of barley to market : I looked at it, and though it was not very fine, I bought it, on account of his letting me have it six-pence a quarter cheaper than I could then buy of others : the lot consisted of one hundred quarters; but when it came home, and I had tried some of it, I think about ten quarters, I was greatly surprised to find the malt so bad; when examining the barley with great attention, I soon discovered the reason of it. Meeting the farmer, of whom I had bought it, within a day or two afterwards, I asked him how he came to sell me mixed barley, adding, that I always thought he kept his grain with more care separate : he soon unravelled the mystery, by telling me, that it was the parson's barley, not his own, which he sold me.

When I heard this, I was not a little displeased; however, resolving to make the best of a bad bargain, I carried a sample of it to market the next day, and sold it to a hog-feeder for eighteen-pence a quarter less than I gave for it. This was some loss; however I was glad to get off so well, as I would not have made the whole into malt, and have imposed on my customers, for an hundred pounds.

To shew that I am not self-interested, I will inform your readers of a method by which they may discover whether malt has been made of mixed, or in part unripe barley. Take a bowl of water; throw into it a couple of handfuls of the malt; give it a gentle stirring, and the barley which has not been malted will sink to the bottom; the half-malted grains will have one end sunk, being in a vertical position; and the true good malt will swim. This experiment I have often made, and never found it deceive me.

The same barley, though ever so good, will not malt alike well at all times : for instance, take it as soon as it is housed, it comes well, but whilst it is in its sweat, by no means; yet after it has done sweating, it comes well again.

In the same manner, barley which has been got in early in a very dry season, makes but indifferent malt; whereas the same barley, if it is left broad till rain falls on it to loosen the husk from the kernel, malts very well, and yields a large increase.

Also, old barley, mixed with that of the last harvest, does not malt well, for the reasons above mentioned; it does not all spear, or put forth its beard, at the same time.

These I know are niceties which few maltsters attend to; yet I am certain that an observance of them, and some few more particulars, would increase their profits nearly ten per cent.

A great many maltsters in the counties of Hertford and Essex, make prodigious quantities of malt for the London market; and there are often disputes happen between the maltsters and the factors and buyers at Mark-lane about the malt not holding out measure; the reason of which many of the country dealers are unacquainted with, and therefore know no other way of guarding against it, than by throwing in a bushel or two extraordinary: this is some abridgment of their profits, and is besides often unnecessary. One reason for this deficiency is, the avariciousness of the maker, who is willing to have as large an increase as possible, to the amount of six pecks in eight bushels; whereas, if the malt is intended for the London market, four pecks is all that can, with propriety, be allowed; for it must not be drawn too long, and this malt requires more cleaning by the screen, &c. than that sold in the country.

Malt, if it is not thoroughly cleaned, will heat in the hold of the vessel that carries it; and the tails, being loosened, will fall off, the necessary consequence of which must be a deficiency when it comes to be measured a second time at the wharf or ware-house: now, to prevent any altercation or dispute, let the maltster always cause his commodity to be well screened before it is measured into the sacks to be carried on shipboard: he need then put up no more than the measure; he will gain himself a character as a clean, good workman; and I will answer for it, that the factors, if he makes his malt according to sample, will readily give him one shilling a quarter more than his neighbours.

MALT-DUST, the dust, &c. that separates from the malt in the act of drying.

The following observations on the benefit of malt-dust, as a manure for a stiff soil, with a relation of some experiments made to ascertain its virtues, appeared in the Museum Rusticum, Vol. III. p. 277.

For the benefit of your farming readers, says this gentleman, I shall communicate a few experiments I made some time since, in order to try the virtue of malt-dust as a manure for a crop of wheat.

I had often heard it asserted, that malt-dust was much better suited, as a manure, to barley than wheat; for the latter lying a whole year in the ground, and the malt-dust being sown with it, the virtues of the manure were exhausted long before the summer, when the corn principally wants nourishment; being advanced in its growth, and served chiefly to make the wheat winter-proud.

Others, contradicting this assertion, said it was best for wheat, and made it appear, that it often caused very good crops of corn, particularly after a hard winter.

Being determined in my own mind to try some experiments, in order to ascertain this matter, I pitched upon a field of ten acres, which had borne a good crop of horse-beans; after which it was sown with turneps, which being fed off, it was summer-fallowed, being intended for heat.

The soil was a stiffish loam: it was in good heart and tolerably clean.

I divided this field by deep furrows into ten equal parts, each containing one acre, numbered 1, 2, 3, 4, 5, 6, 7, 8, 9, and 10:

The whole field during the course of the fallowing had four ploughings which reduced it to a fine tilth.

When wheat seed-time came, I sowed number 1. broadcast, with three bushels of wheat, and ploughed it in, laying on no manure whatever.

Numb. 2. I sowed with the same quantity of wheat, after which I strewed over it ten quarters, or eighty bushels of malt-dust, and ploughed that and the seed in together.

Number 3. I sowed also with wheat in the same manner, except that I deferred strewing on the malt-dust, till the latter end of January.

Number 4. had a dressing of dung in the ordinary way

and was sowed with three bushels of wheat like the other parts.

Number 5. was dressed by sheep-folding, and was also in like manner sown with wheat.

Number 6. was sown with wheat in the same quantity; and in February, after sowing, received a half dressing of very rotten dung, which had been several times turned and mixed:

Number 7. after receiving a ploughing in the spring, was sown with ten pecks of barley, which was harrowed in, and no manure at all applied.

Number 8. was sown with barley, as above, but had ten quarters of malt-dust laid on it.

Number 9. had in the winter a good dressing of dung, and was in the spring sown with the same quantity of barley.

Number 10. was sown with barley, like number 8. only it had five instead of ten quarters of malt-dust laid on it.

It may be necessary perhaps to observe, that all the pieces of wheat were sown the first week in October, and all the barley the second week in March.

Soon after Christmas I went to take a view of my wheat, when I found that the acre marked number 2. looked most forward and flourishing; though I must own there was in appearance but little difference between that and number 4.

The numbers 1, 3, and 6. neither of them looked so vigorous as those already noticed; and number 5. seemed rather thin on the land; but the wheat plants were in good condition and healthy.

In May I took another view of my wheat crops, and found number 1. tolerably clean, and promised well.

Number 2. gave me hopes of a large crop, and was surprisingly clear of weeds.

Number 3. was greatly improved since the laying on of the dressing of malt-dust.

Number 4. looked very vigorous and strong, but was very foul, having several sorts of weeds not to be met with in other parts of the land.

Number 5. was thin of plants, and they did not branch much; however they still seemed healthy and strong.

Number 6. was like number 3. greatly improved; but it was foul, and what appeared strange to me, had many weeds of a nature quite different from those with which number 4. was infested, though the dung laid on both these parts was taken from the same heap.

I at this time also looked at my pieces sown with barley, when I found number 7. promising and clean.

Number 8. was forwarder, and flattered me with the prospect of a large crop.

Number 9. was forward and fine, but foul with weeds.

Number 10. bore much the same appearance as number 1. and promised as well.

At harvest, number 2. of the wheat was first fit to reap, after which succeeded number 4. the rest were ready nearly at the same time.

Of my barleys, number 8. and 10. were first ready to mow.

I suppose it is unnecessary to observe that those crops which were cleared of weeds were the soonest fit for carrying.

I ordered these crops to be all laid separately; and as I was obliged, just after Michaelmas, to go up to London, about some particular business, I left orders with my bailiff, that they should all be separately threshed and dressed as early as might be in the winter.

The produce of the several crops was thus distinctly noted to me, for I had ordered that particular care should be taken not to mix one with the other, and my orders were, I found, on enquiry, punctually carried into execution.

	Bush.	Pecks
Number 1. unmanured, yielded of wheat	20	1
Number 2. manured with malt-dust when sown	28	3
Number 3. manured with malt-dust after Christmas by way of top-dressing	41	0
Number 4. manured with dung in the ordinary way	32	2
Number 5. folded with sheep	29	3
Number 6. dressed with rotten dung in February	30	0
Number 7.		

	Busb.	Pecks
Number 7. unmanured, yielded of barley	32	3
Number 8. manured with ten quarters of malt-dust when sown	48	0
Number 9. manured with dung in the winter	40	2
Number 10. manured, when sown, with five quarters of malt-dust	44	0

I must, with your leave, trespass upon your reader's patience, till I make a few observations on the above state of the produce of my crop.

First, I conclude, that when malt-dust is used as a manure for wheat, it is the best to lay it on by way of top-dressing after the corn is come up, as the crop of numb. 3. yielded above twelve bushels more than that of numb. 2. and I am apt to think that the virtue of the malt-dust laid on number 2. was exhausted before it could be of any essential service to the crop; whereas, in number 3. the manure began to yield forth its virtues just as the wheat plants began to be in want of a fresh supply of nourishment. It was also observable, that the grains of wheat which grew on number 2. were thinner, and had less substance, than those of number 3. the grain of which was fine, plump, and heavy.

The produce of number 4. convinces me that malt-dust is, in many cases, a better manure for wheat than dung, not only as it gives a larger increase, but also because it does not stock the land with destructive and devouring weeds.

The wheat grown on number 5. was as fine as that of number 3. but considerably less in quantity, as appears by the account.

I do not much approve of the method pursued in number 6. yet is it a good alternative, if the farmer happens to have too little dung to dress all his fallows.

I judge also malt-dust to be a very good and profitable manure for a barley crop; but the yielding of number 10. being forty-four bushels, and of number 8. only forty-eight bushels, which last is not an increase in proportion to the additional quantity of manure laid on, I thence judge that eight quarters, or sixty-four bushels, of malt-dust, is the proper quantity of malt-dust to lay on an acre for a barley crop, and that at the time of sowing.

When I speak of malt-dust, I mean the kiln-dust which falls from the malt in drying: as to the tail-dust, which falls through the screen whilst the malt is cleaning before it is put in sacks, that may be applied to a better use, being generally given to pigs, and often to cows, in which last case it makes them give a great deal of milk.

It has been suggested that the virtue of malt-dust, as a manure, lasts only for one crop; but this is a mistake, for when this manure is laid on in January or February, a good crop of barley may be had after the wheat.

It (I mean malt-dust) is of a very warm nature: this has induced many farmers to think that it will burn a crop; and I will not answer for it but it might do so on a hot gravelly soil; but on clay land, or a stiff loam, it seldom or never does any damage: and indeed the only danger is a dry time ensuing after it is spread on the land, for the first shower of rain washes it in, and secures the crop from all hazard of being burnt.

Many of my acquaintance, besides myself, have found that malt-dust is for a stiff soil a better manure than dung; but the dispute among them was, whether it was most profitable to lay it on when the wheat was sown, or by way of top-dressing in January or February: however, since I made the above experiments, they are all converts to my opinion, and are determined in future always to dress their heavy wheat land with it after Christmas.

One thing more in recommendation of this my favourite manure let me add before I conclude, that nothing surpasses it when laid on cold grass grounds, to the amount of about eight quarters or sixty bushels on an acre, but not less.

Such as have not seen its effects in this way applied, would be surprised at the large increase of sweet feed which it occasions: in short, whoever finds it necessary to dress such land, and can get malt-dust in a sufficient quantity, will do well to use it, as they will be puzzled to find any thing in the extensive circle of manures better adapted to the purpose.

MANGE, IN HORSES, is caused by over heat or cold, hard riding or labour, by which the blood is corrupted; or it may be occasioned by eating unwholesome food.

The distemper may be easily known by the staring of

the hair, its coming off from the skin in many places, and a scurf arising thereon.

When the distemper is caught by infection, an ointment composed of flour of sulphur and hogs-lard, will effectually cure it, if rubbed in every day immediately after the misfortune is perceived. In the mean time sulphur and antimony should be given with his feeds, and continued for some weeks after the cure is performed, in order to purify the blood. If the sulphur ointment should not be thought agreeable, a liquor made by steeping tobacco in stale chamberlye, will answer the same intention; but the sulphur and antimony should be given with his feeds.

But if the distemper has been of some continuance, or if it owed its origin to low feeding, and a poverty of the blood, other methods must be pursued, the diet must be mended, and the horse indulged with a sufficient quantity of hay and corn, and the following ointment rubbed into the parts affected every day: Take of sulphur vivum, half a pound: of crude sal armoniac, one ounce: and of hogs-lard a sufficient quantity to make the whole into an ointment.

Give him every day a feed of scalded bran, and when the disease begins to disappear, the following purge:

Take of succotrine aloes, ten drams; of diaphoretic antimony, half an ounce; and of fresh jalap in powder one dram: make the whole into a ball, with a sufficient quantity of Bardadoes tar, with sixty drops of chemical oil of aniseeds.

If the case prove very obstinate, wash the mangy parts with sublimate wash, and give the brimstone inwardly.

If poor feeding and hard work is the cause, the cure will be obvious;

Sublimate Wash.

Take of sublimate mercury, half an ounce; lime-water, a pint; mixed.

When the horse is thoroughly cured of this distemper, it will be necessary to wash the floor of the stable very well with soap-suds, and fume it well with burning pitch or charcoal. His cloaths also should be laid in scalding water, washed very clean with soap and thoroughly dried, before they are used again; for if these precautions are not used, other horses will be liable to the infection.

Another method of cure is: Take staves-acre seeds, two handfuls, infuse it in a quart of strong vinegar and hot ashes; wash the mangy parts with this liquor, and it will cure it in twice bathing.

MANGE in a dog, a distemper with which he is often affected, for want of fresh water to drink when he is thirsty, and sometimes by not being kept clean in his kennel, or by foundering and melting his grease.

For the cure: Take two handfuls of wild cresses, and as much elecampane, and also of the leaves and roots of roerb and sorrel, and two pounds of the roots of foderls; boil all these well together in lee and vinegar, strain the decoction, and put into it two pounds of grey soap, and when it is melted, rub the dog with it four or five days successively, and it will cure him.

MANGER, the place or vessel in which the horse's corn is put.

MANURE, a general name for soil of all kind laid upon land to improve it.

Mr. Marshall, in his Rural Economy of Norfolk, recommends the following method of manuring:

"For turneps, the stable-muck is usually carried out, from time to time, as it accumulates, or as the weather answers, in winter: and the par-muck, wanted for this crop early in the spring; and piled up in heaps in or near the intended turnep-closes; a bottom being previously formed of marl, or manure, about a foot thick, and neated up into a long square bed to set the pile upon.

"The method of carrying out farm-yard dung, when a farmer wants to get business forward, is generally this: Two fillers, a driver, and an unloader, with six horses and three carts, are a set, for a short distance: one of the carts being always in the yard, one on the road, and one at the dung-heap; it being an universal practice, which prevails throughout the district, to set the carts by the side of the heap and unload them with forks.

"The crime of drawing the load on to the heap is rarely committed in Norfolk. On the contrary, every lump is carefully broken, and the whole piled up light and even,

even, with almost as much care and attention as farmers, in some places, bestow upon their hay-ricks.

"The ordinary day's work of the set abovementioned is twenty-five loads; if the distance be very short, thirty loads are frequently carried out: in this case, however, an additional boy is required to assist in levelling and forming the heap.

"The filling is generally done by the load; another admirable practice: the price one penny a load; a striking instance of the low wages and hard work of this country.

"This practice ought to be copied in every country; for it would, in most places, be cheaper to pay even three-pence a load, than to have the dung cart filled by the day; in which case, the team is ever standing idle until the load be made up: whereas, when the filling is done by the load, that seldom happens. This accounts sufficiently for the extraordinary number of loads carried in a day, in Norfolk.

"For wheat, the remainder of the par-yard-muck is generally, in the spring, after the cattle are turned out to grass, turned up into piles in the yards, where it remains until the soil be prepared to receive it; the piles being by good farmers returned in the summer; an operation, however, which is too frequently neglected.

"Or, instead of turning the piles in the yard, they are sometimes carried, at leisure-times in summer, on to the land, and there piled afresh: in either case, the compost, by the time it be wanted to be set on, is thoroughly mixed and digested.

"The method of setting on dung is similar to that of carrying out: and from twenty-five to thirty loads are considered as a day's work for one team and two fillers: all set on in hillocks.

"The quality set upon an acre is, of course, proportioned to the quantity of land to be manured, and the quantity of dung to be set on: ten loads of good spit-dung, or twelve to fifteen loads of compost, is, perhaps, the medial quantity set upon an acre, for turneps:—for wheat a smaller quantity, and generally of a worse quality, is usually allowed.

"Some few farmers manure their clover-lays, but this is by no means common; the application of dung being, as has been said, in a manner wholly to the turnep and wheat crops.

"It may also be said, in general terms, that all the dung spread upon this district is plowed in; wheat is sometimes top dressed with it; but I have met with few instances of that species of management." See DUNG.

The following Letter, sent to Dr. Templeman, Secretary to the Society for promoting Arts, &c. to be by him communicated to the Committee of Agriculture, in Recommendation of a new Manure, is of too much Importance to be omitted here.

"S I R,

"As a farmer, like a chymist, should lose none of his materials, but make even his washings, runnings, and residuums, turn out to his advantages, I have sent you some account of an experiment I have made in manuring of land, which I beg you will lay before the Committee of Agriculture, that they may communicate it to others.

"I am possessed, sir, of a farm of near three hundred pounds a year, and have in my yard, what you usually see in most farmers yards, two recesses or pools, as reservoirs of dung and water. These reservoirs in wet weather are continually running over; and of course part of the matter contained in them is carried off, by the necessary drains, into the highways, ditches, and rivers.

"As much of the essential quality of the dung is lost in this manner, (for part of the salts, whether fixed or volatile, will be washed into the pools, and when they overrun will be conveyed into the ditches, &c.) I thought it a part of good husbandry to carry this superabundant water, or manure, (for so we may justly call it) on my land, which I did by means of a watering-cart, not unlike those with which the roads near London are watered in the summer-time to allay the dust.

"That the experiment might be the more obvious and certain, I first tried it (in the beginning of March, 1763) on a few acres in the middle of a large meadow, and on some lands in the middle of a large field of wheat, where, in a little time, I found a considerable increase, in growth, both of grass and grains; and at hay time and harvest, both the one and the other were much better crops

than what the same lands produced that were not so manured.

"As a man, or even a boy, with one of these carts, and one horse, may manure a great deal of land in a day, provided it be near the yard, I would recommend the practice to all my brother farmers; for the expence is nothing, but the value of the time of the boy and the horse; and the increase, by what I have seen, will be very great.

"This manure may be also laid, to great advantage on land that is fresh sown with barley, oats, or any other grain; but on grass it should be only laid in the winter time, when the rains will wash the salts off the blade; or in the spring, when the lands are laid up for hay; as the cattle will not feed on the grass, while the dung, or salt, adheres to the blade of it.

"This dung-water should likewise be carried on the land, not at a time when it rains, but in the dry weather, and at a time when the dung water in the pools is of a deep brown colour, and strongly impregnated with salts. By this means the land may be manured from time to time, and the pools kept almost empty for the reception of fresh matter every time it rains; and nothing will be lost."

MARE, the female of the horse. See the article HORSE.

Such mares as are designed for breeding, ought to be as free from defects as possible, and should, no more than the stallions, have either moon-eyes, watery eyes, or blood-shot-eyes; they should have no splint, spavin, or curb, nor any natural imperfection; for the colts will take after them; but choice should be made of the best and ablest, the most high spirited, best coloured, and finest shaped; and the natural defects that may be in the stallion, should be amended in the mare, as well as that which is amiss in the mare should be amended in the stallion.

As for her age, she may be covered when three years old; but the most convenient time is after four, when she will nourish her colt best; and though she may breed till she is thirteen, yet she is not fit for it when she is past ten, for the colt of an old mare is commonly heavy. Before a mare is covered, she should be in the house about six weeks, during which time she should be well fed with good hay, and oats well sifted; and in order to render her conception the more certain, near a quart of blood may be taken from each side of her neck, about five or six days before covering. Another method to bring a mare in season, and make her retain, is to give her, for the space of eight days before you bring her to the horse, about two quarts of hemp-seed in the morning, and as much at night; and if she refuses to eat it, to mingle it with a little bran or oats, or else to let her fast for a while: and if the stallion also eat of it, it will greatly contribute to generation.

Mares go with foal eleven months and as many days as they are years old; and therefore the properest time for covering them is in the beginning of June, that she may foal the May following, when there will be plenty of grass, which will afford the mares a great abundance of milk for nourishing their foals: but a mare should never be covered while she is bringing up her foal, because the foal to which she is giving suck, will be prejudiced by it, and she herself sooner spent. After covering, let her, for three weeks or a month, have the same diet as before, and kept clean in the stable till the middle of May, with her feet well pared and thin shod: take her in again about the latter end of September, if not before, and keep her to the end of her foaling. If she cannot readily bring forth, hold her nostrils so as to stop her taking wind; and if that will not do, dissolve madder, to the quantity of a walnut, in a pint of ale, and give it her warm. In case she cannot void her secundine, or after-burden, boil two or three handfuls of fennel in running water, then put half a pint of that liquor into as much sack, or, for want thereof, into a pint of ale, with a fourth part of sallad-oil, mixed together, and pour it lukewarm into her nostrils, holding them close for some time: otherwise give her green wheat, or rye, the last of which is best.

If the mare has but little milk, boil as much as you can get from her, with the leaves of lavender and spike, and bathe the udder with it warm, till the knobs and knots are dissolved. She should now drink only white water (which is bran put in water; give her also sweet mashes): and a month after foaling, let her have a mash with some brimstone or sarsine in it.

MARLE, a kind of dry, soft, siltie earth, used in manuring land.

Marle

Marle is either grey, blue, brown, yellow, red, or mixed, and is known by its pure and uncompounded nature: besides which, it is distinguished by several other marks, such as, its breaking into little square bits; its falling easily to pieces, by the force of a blow, or upon being exposed to the sun or frost; its feeling fat and unctuous; and its looking, when dry, after having been exposed to the weather for some time, as if it was covered with a hoar-frost, or sprinkled with fine salt. Even when mixed with the land intended to be manured by it, the whole surface of the soil will have that whitish appearance. But the most unerring way to judge of marle, and know it from any other substance that may resemble it, is, to break a piece as big as a large nutmeg, and, when it is quite dry, drop it into a glass of clear water, where, if it be the right sort, it will soon dissolve into a soft and almost impalpable pap, shooting up many sparkles to the surface of the water. Some marles effervesce but little with acids: but they should always be put to that trial; because the more they effervesce with them, the more valuable they are as manures. In hot weather, good marle will flake with the heat of the sun, like lime: especially if any rain follows a hot day.

The farmers in Staffordshire reckon the soft blue marle, which is most commonly found under clay, or low black ground, at the depth of seven or eight feet, the best for arable land, and the grey sort the best for pasture. That which is of a brownish colour, with blue veins in it, and little lumps of chalk or lime stone, generally lying under stiff clays, and very hard to dig, is most esteemed in Cheshire. The marle which is usually found at the depth of about two feet, or a yard, on the sides of hills, and in wet boggy grounds which have a light sand in them, is very fat and close, and reckoned the strongest of all marles; for which reason it is particularly good for sandy lands. This is commonly called peat-marle, or delving marle. The paper-marle, as it is sometimes called, frequently lies near coals, and flakes like leaves or pieces of brown paper, than which it is of a somewhat lighter colour. That which some writers call clay-marle, because it looks like clay, is very fat, and sometimes mixed with chalk-stones. Steel-marle breaks of itself into squares cubical bits. These two last kinds generally lie under sand or clay; sometimes about a yard deep under the former, but often much deeper under the latter.

Stone, slate, or flag marle, which is a kind of soft stone or rather slate, of a bluish colour, is generally allowed to be the best. It easily dissolves with frost or rain, is found near rivers and on the sides of hills, and is a very lasting manure. An ingenious gentleman, passing lately through Bedfordshire, observed; that the people employed to mend the highways, were laying upon them a bluish kind of stone. Struck with the novelty of the appearance, he stooped, took up a lump, and soon found it to be this blue marle, which the ignorant peasants were using instead of real stone. The consequence was, that when he returned the same way some time after, a heavy shower having fallen, the old road where this substance had been so injudiciously spread, was become a perfect quagmire.

Mr. Markham reckons four sorts of marle, in Suffex: viz. grey, blue, yellow, and red. The blue is accounted the best, the yellow next, and then the grey. The red is the least durable. A great deal of the marle in the north country runs much upon the loam; but that in Suffex is more like fuller's-earth, and therefore must certainly be the fattest.

Mr. Mortimer says, he saw a sample of marle from Derbyshire, which was very fat, though it contained so much sand, that when wet, it could not be worked into a ball, or be made to hold together. This marle did very well upon clayey land, because it was of an opening quality.

In many parts of most counties in England, marle discovers itself to the most negligent eye; particularly on the sides of broken hills, or deep hollow roads. Many rivers are bordered with a vast treasure, which is plundered by every flood. Boggy lands frequently cover it; and, in them, it seldom lies above three feet deep. It is somewhat lower under stiff clays, and marshy level grounds. The lowest parts of most sandy lands abound with it, sometimes at the depth of three feet, and sometimes at seven, nine, or more. The depth of the marle itself can seldom be found; for when the upper crust of the earth is re-

moved, all that can be seen or dug is marle, to so great a depth, that there are few, if any, instances of a marle-pit's having been exhausted.

Nothing is more common than to find the ditches which inclose a field, dug so deep that they have penetrated six or seven inches into a bed of marle, without the farmer's taking any notice of it; though the extraordinary shooting and increase of the grass which is put forth by the marle thrown up on the sides of the bank, might, one would think, be a means of discovering it. Where the marle is thus accidentally disclosed, it not only turfs the sides and tops of the banks, and thereby secures them against all injuries of the weather, but makes the grass grow so long and thick, that, when beaten down by winds, it hangs as if it thatched the earth which nourished it, and carries off the rain, without letting any great quantity penetrate through it.

The marquis of Turbilly, in his excellent directions for clearing and breaking up land, recommends, for boring it (in order to know what different layers of earth, ores, quarries, springs, &c. lie underneath, and at what depth, by which means the better judgment may be formed of the plants most proper for the soil), an instrument of his own inventing, as far superior to any thing that has yet been thought of for that purpose. A description of it may be of service to every ingenious improver of land. See the article BORER.

Marle is very common in Ireland, where it seldom lies above a foot or two below the surface of the soil; luckily for that country, which is extremely boggy. But in France, though they have marle in many places, they are often obliged to dig for it very deep, particularly in the province of Artois, where it generally lies eighty or ninety feet under ground, in beds about five feet thick, at the bottom of which frequently is water, which breaks in upon the workmen. On account of this great depth of the marle-pits there, extraordinary care is taken to set up marks, and rail them in, to prevent the fatal accidents which might otherwise happen. The same is, indeed, done in England; but not so strictly as it ought to be.

Authors differ widely both as to the quantity and the manner of using almost all the manures they treat of; points which must, in a very great measure, depend on the quality of the soil, and the strength of the manure, of whatever kind it be, in which experience will ever be the judicious farmer's surest guide. In marling, it is particularly necessary to find the true proportion which the land requires, and better to err in laying on too little, than too much; because more may be added at pleasure; whereas by over-doing it, the first year's crop often fails, because the body of the marle has not been sufficiently opened; and, in that case, it will sometimes be two or three years before the ground comes to a proper temper. The best directions that can be given to the farmer in the application of this manure to light soils, is to lay on the quantity which will give the degree of cohesion wanted in those soils. A general rule cannot be laid down in this respect, because, the quantity of marle requisite to effect the desired end, must be different, in proportion to the degree of lightness of the soil.

Pliny speaks of marle as a species of improvement known to the Greeks, but more peculiar to Britain and Gaul. He calls it, the fat of the earth, and compares it to the glands in the human body, which are lapped in a coat of fat. As this manure, so far as we can find, was not used, and probably not to be found, in Italy, it shews how attentive the Romans were to agriculture, wherever they carried their victorious arms; since, notwithstanding the continual alarms they lived in from the natives here and in Gaul, they found time to discover and perfect a means of improving land, particularly suited to the soil and climate, and, of all others, the cheapest and most lasting.

Before we quit this subject, we must observe, with Dr. Home, that a body very similar to marle in its appearance, but essentially different in its effects, is often found in the same bed with the best marle. It is of a darkish lead colour. Instead of fertilising the earth, it renders even the best soils incapable of bearing any kind of vegetables for many years after. I have seen, says that gentleman, the spots on which it was laid, entirely barren three years after; and have heard of its bad effects continuing in other places for a much longer time; nor is it certain when they will cease. A body so very destructive to agriculture, deserves to be well characterised, in order to its being shunned;

shunned; and should be thoroughly examined, that we may know whence proceeds this noxious quality, and how to cure it when it has taken place.

Marle takes a smooth polish from the instrument with which it is wrought. A piece of this taken up, when it has not been much exposed to the influence of the air, differs greatly in taste from marle. Instead of the smooth unctuous taste of the latter, it is acid, and remarkably astringent. It agrees with marle, in crumbling in water, but differs remarkably from it in not raising any effervescence with acids, nor in the least destroying their acidity. It turns the syrup of violets red; which shews that it contains an acid: whereas marle, like all absorbent earth, gives it a green colour. The trying of marle with acids, is therefore the more necessary, to guard against using this pernicious substance.

It appears from experiments made by the doctor, that this pernicious substance consists of an earthy body like clay, about an eighteenth part of salt of steel, and a small proportion of the vitriolic acid: from whence he concludes, that good marle is the proper cure where this noxious earth has been inadvertently used; because it corrects the acid, and decomposes the salt.

The following account of marle was sent by a very intelligent gentleman to the editors of the *Museum Rusticum*.

A short Dissertation on Marle.

It is taken out of the bowels of the earth at several depths, is of divers colours, as after named, and some sorts have often two or three colours intermixed. It is unctuous, of a slippery nature, and in goodness pure; soon relents after rain, and, when dry, flakes like lime, and at last dissolves into the finest powder.

I intend to leave with you some specimens of two kinds of marle (which you may give to the gentlemen or farmers who desire them): they are what I have collected in Middlesex, which county abounds with good marle; but it is not used by the gentry, or farmers, so much as it ought, because they have so readily dung, soot, ashes, and other composts, from London.

In order to discover marle, the best way is to use the auger, and observe the strata taken up from time to time by it.

I have found, after I have got through the surface, which is about a spade and a half deep, that the next earth was a very strong, coarse, bed of clay five or six feet deep; afterwards, getting through it, the auger brought up marle, viz. that which appears of a fine light-brown colour, and some of it mixed with blue veins (which I will here call pigeon-marle, by way of distinction): here was a bed of this pigeon-marle of five or six feet deep, and after that followed another kind of marle, which I will call toad-marle, by way of distinction; this is heavier, and without any veins of blue.

When either of these marles are dug out of the pit, the spade cut them like so much soap; and the last-named marle looks very blackish and dark, and may be, and I believe is, in some countries, called toad-marle, from its resemblance in colour to that animal; but this marle being exposed to the air alters the colour very much. This appears to me to be the strongest marle.

Marle may be discovered sometimes near the surface, by carefully observing the ditches and fences of your lands.

It is frequently found near rivers, or brooks, and sometimes may be discovered on the banks of such waters.

To know when you have found true Marle, try it by Air, Fire, and Water, or Vinegar.

First, by exposing a large lump of three or four pounds in the air, which, if true marle, will, in a little time, by the nitre, dews, &c. break into small parts; and there will be an hoary, or white congelation on that part of it which is exposed to the sun.

Secondly, when your marle is dry, break it into small particles, and put an handful into a hot coal fire, and it will crackle as if so much salt had been put therein.

Thirdly, place a piece of the dried marle in a glass, and thereon gently pour as much water as will cover it. If true marle, it will then gradually moulder, and dissolve into

a liquid soap. Let not the glass be shaken, that you may observe the ebullition (which is material); or you may, in like manner, try it with vinegar, where the effervescence, or struggling, will be much stronger than in water.

The Virtues of Marle.

It is the best manure for sandy, dry, gravelly, or light lands of any kind. It is excellent for mossy lands. It is, indeed, good for all other lands, of what nature soever, even clay, provided care be taken in laying on a proper quantity, and that the same be well dissolved.

Care must be taken in the quantity used; if too little, you may easily add; but if too much is laid on the land, you cannot take it away.

It is used in some countries for arable lands only: yet it is as good for grass or pasture lands, but does not the first, and seldom till the second year, shew forth its utility; and then you will observe the grass to shoot out a dark, or blackish colour, which afterwards turns to the finest green; and with it come up quantities of white clover-grass, which hath occasioned me some difficulty with the farmers to convince them I had not sown the clover seed.

If lands are properly marled, they will continue good for twelve or fourteen years for the plough: and for pasture, or grass-lands, much longer.

I would recommend that the plough be not suffered to enter into the land till the marle is thoroughly dissolved.

Fish thrive prodigiously, and grow fatter in marle-pits than any other ponds.

Quantities to be used.

A great difficulty is to ascertain the quantity.

In some countries they will tell you of laying three hundred loads to an acre, others more, others less; but they nowhere ascertain what is a load. In Cheshire and Lancashire the loads are scarcely six bushels, and they use a small cart made for the purpose, drawn by two or three small horses.

If the land is gravelly, sandy, or light, let as much be laid on it as will make a good thick coat to bind and stiffen the soil.

But let the land be what it will, so much should, in all events, be laid on as will make a thin coat over the entire surface.

Upon my lands, which are grass and pasture, of a tolerable mould, on a clayey soil, and which were left, about eight years since, in a bad plight, by the late tenant, I first attempted to lay ten loads to every acre (by a load I mean as much as three large, well fed, strong horses could draw); but found it was too little, and would not meet in the spreading.

I immediately doubled the quantity, and two years afterwards I added another coat of fifteen loads more to every acre, and find it answers very well for hay and pasture. I need not say horses and cows are fonder of this hay and grass than of that wherein the dung may be tasted and smelt.

A work of this kind should be set about by the end of August, or beginning of September; and the loads should be shot into small heaps, as the Middlesex farmers shoot their dung, viz. two or three bushels in each heap; and a man must be ready to separate it, that the nitre, air, dews, and rain, coming on the large pieces, may act, and cause them to break, as of themselves, into smaller parts.

After the marle has been laid upon the ground, and you see that the air, nitre, &c. have loosened the great lumps, and they are ready, on a slight touch, to fall into pieces, a person should be ordered (when the weather and marle are quite dry) to break and spread the pieces to complete your coat; and you should avoid as much as possible, leaving any large pieces to lie and dissolve without being spread on the surface, but cause them to unite therewith.

In the beginning of February, and in dry weather, I cause an old gate to be well bushed, and a heavy weight laid on it, to be drawn by one horse over the whole field, in order that every part may have its due proportion.

If you intend to plough your lands, the preceding cautions are not so necessary, as the plough and harrows will spread and intermix the marle with the soil sufficiently; but if you use the drill-plough, the above hints may be useful.

It would take a volume to give an exact and full history of

of marle, its virtues and uses, and to shew that it was used by the Romans, and many years discontinued; and especially till the houses of York and Lancaster were united, and then revived in some few counties; and the great benefits received by marling in Suffolk and Norfolk within a few years past.

We very well know that gentlemen and farmers are a long while ere they care to venture on the practice of marling from theory, and principally from not having seen or known what is, and what is not, true and genuine marle, and from being unacquainted with the rules or modes to judge and determine upon it: therefore, if this short account will obviate their doubts, and in any way contribute to the advancement of agriculture, vegetation, and pasturage, my design is answered.

There are variety of colours in marle, viz. blue, white, yellow, red, and other colours, which make no material difference, provided they be earthy and fat, or slippery as soap, and as free as possible from a mixture of sand, gravel, or stone.

Mr. Marshall, in his Rural Economy of Norfolk, says that "Marle has been so long in use in this district, that there are few farms without marle-pits upon, or near them; so that searching for marle is at present seldom requisite, and the art of discovering it not much studied. The herb colts-foot (*tuftilago farfara*) abounding on the soil, is considered as an indication of a jam of marle being situated near the surface. But, whether this is, or is not, an infallible guide, time and accidents or intentional researches have not failed to discover beds of marle in almost every estate, and, in some places, on almost every farm, situated sufficiently near the surface to be worked with advantage.

"Of the quality of marles, the Norfolk farmers are, in a great measure, uninformed. That which falls most readily, and "gets to work" the soonest, is in the best esteem; but, in general, the quantity of "uncallow" (namely, the coping, or covering of earth, which lies upon the head, or jam) is more attended to than the intrinsic quality of the marle.

"The depth of uncallow is generally very unequal: perhaps, on the same jam of marle it will vary from one or two, to six or eight feet deep, the surface of the jam usually rising into inequalities, termed heads.

"The depth of the jam is equally uncertain: I have seen one worked twenty feet deep; but in general, I believe, ten or twelve feet may be reckoned a middling depth.

"The bottom of the jam, being generally a white absorbent sand, no pump or artificial drain is requisite to free a Norfolk marle-pit from water, which no sooner touches the sand than it vanishes, as through the grate of an open drain.

"In working a marle-pit, the top-soil is thrown back for manure: the remainder of the uncallow thrown to the bottom of the pit, and levelled for the carts to stand upon. When the jam is low, the marle is thrown immediately from it into the carts; but if it be too high for this operation, piles are driven in a row a few feet from the face of the jam; and, as soon as a crack is formed, water is poured into it, more especially when the marle is dry and stubborn; and by this means many loads are thrown down at once; either to the bottom of the pit, or on to a platform level with the body of the cart; into which the marle, in this case, is thrown with great ease. Taking up the bottom of the jam is the most difficult part of the operation; the marle being first to be cast up on to the bottom of the pit, and afterwards to be thrown into the carts. But by thus bringing up the bottom, two valuable things are obtained; a drain for the water, and a most convenient receptacle for the next line of uncallow.

"The labour bestowed on marle previous to its being put into the cart, whether it be incurred by throwing down, loosening by pecks, crows, &c. or fetching up the bottom, is termed "casting"—the act of throwing it into the cart being called "filling."—The price of casting is three-pence to six-pence a load, according to the circumstances of the pit (the uncallowing being generally done by the day); and the price for filling two-pence to two-pence half-penny, according to the size of the loads carried. I have known three pence a load given for filling and spreading large loads: the price of spreading, alone, is about one shilling an acre. The number of loads carried out in a day by one team, varies, of course, with the dif-

tance to be carried: when the pit happens to lie in or contiguous to the ground to be marled, thirty loads have been carried: but five-and-twenty is, I believe, considered as a good day's work.

"The quantity set upon an acre is equally various; depending upon two things:—upon the judgment of the person who marles, and upon whether the land has, or has not, been marled heretofore.

"It is known, from common experience, that land which has been recently marled receives no apparent benefit from a second dressing of the same manure: but it is equally well known that, after some length of time has elapsed, a repetition of marling will generally answer.

"It is a notion, pretty generally adopted, that, in this case, the quantity ought to be greater than it was the first or preceding time: and it being formerly the practice to set on a great quantity at once, seldom, perhaps, less than forty loads an acre,—this notion has, probably, deterred many persons from doing that which would have been serviceable to themselves and their country.

"But there is not, I believe, any general rule known, respecting either time or quantity: I have had frequent opportunities of making observations on a farm which affords a striking instance on this subject. Two or three different tenants had failed successively on this farm; though by no means high-rented. The greatest part of it had, within the memory of man, been marled with not less, in all human probability, than forty loads an acre; and the tenants who failed, despaired of reaping any benefit from a second marling after so short an interval of time: but this farm falling into the hands of a more judicious tenant, he has, by marling, (and by other acts of good management) accumulated, in little more than twenty years, a farmer's fortune; during which time he marled upwards of one hundred acres; and has found, from long experience, that twenty-five loads an acre is, notwithstanding the recent marling, a sufficient quantity.

"I do not mean to intimate that the same management would every where produce the same effect; but I will venture to say, that no man having marle upon his premises ought to neglect to try its effect, by accurate and repeated experiments, upon every piece of land in his possession, without being led away by any received notion, or general rule.

"The quantity set on, upon land which is not known to have been marled, or out of which the marl is worn, is, at present, less than formerly.

"In the southern Hundreds, to which marle is obliged to be fetched a great distance, ten or twelve loads are considered as a dressing; six or eight are frequently set on.

"In the more central and northern parts of the district, where marle is common on almost every farm, twenty to thirty loads an acre are generally allowed, and sometimes forty loads.

"When it is known, from experience, or taken for granted without proof, that land, either through a recent marling or other cause, is not improveable by marle alone, a small quantity is frequently mixed up with dung; either by bottoming the farm-yard, or the muck-heaps, with it; or by mixing it layer for layer with the dung in the heaps. In either case, they are afterward turned up, and thereby mixed more intimately together. With this preparation, marle has been found to answer, where, in its natural state, it had no effect.

"The symptom, or indication, of a piece of land requiring to be marled, is taken from the plants which prevail upon it. "Buddle" (*chrysanthemum segetum*, corn-marigold) is considered as a certain intimation that the land it abounds upon requires to be marled. "Smartweed" (*polygonum Pennsylvanicum*, pale-flowered persicaria) is likewise an observable symptom. It is, I believe, an undoubted fact, that marle, in a manner, extirpates these plants from the soil; and that "quicks" (*triticum repens*) are considerably checked by it."

DICE-MARLE, a name given by the people of Staffordshire to a reddish marle, that breaks into small square pieces like dice, or into thin flakes, in the manner of lead ore, and looks smooth on the surface.

Marle is distinguished by several names, but principally by the four following:

1. Clay-marle, so called because it resembles clay, though a very different body.

2. Stone-marle, which approaches to the hardness of stone,

stone, and is therefore easily distinguished from clay-marle, which is soft, and is of slower operation.

3. Slate-marle; this lies in thin layers resembling slate, and is also harder than the clay-marle.

4. Shell-marle; which is a composition of earth and small shells. It is of a lighter substance than the others; lies near the surface of the earth, in low grounds, that have formerly been overflowed with water; and sometimes near the sea. This is a very rich manure, and of quicker effect than either of the former.

Marles are all compounds of the same kind of materials, in different proportions, viz. a calcareous earth, clay, and sand; and in some marles are found some shining flakes of foliaceous talc, unsoluble in acids, and very little altered by fire.

There are several kinds of earths that resemble marle, some of little use as a manure, and others that are pernicious to land, as before observed. The colour and appearance are no certain indications of the quality of marle, which the farmer should know, before he ventures to lay upon his land any earths as marle, the quality of which he has no experience of. Farmers having no certain rule of judging this, have been fearful of using marle; which has deprived them of the benefit of this excellent manure, which is to be found in many places, and might be of much more general benefit, did the farmers know how to distinguish it. The ingenious Dr. Ainslie has lately made very curious experiments upon the several sorts of marle, which are the more valuable, as farmers may themselves perform them; which they are advised to do, and to search for marle, by digging and boring; and when they find any earths resembling marle, they may discover with certainty, whether they or any of them is genuine marle, by the following easy process:

1. Put a little fresh dug clay-marle into a glass, and pour upon it as much water as will cover it; the marle will soon dissolve in the water, into a soft soapy substance. Or if exposed some time to the air, it will fall down into a fine powder.

2. Marle effervesces with all acids; a little of it put into a glass with vinegar, a brisk motion will immediately be excited; it will effervesce, sparkle and rise like wine or cyder, and air-bubbles will continue to rise, till the acidity of the vinegar is destroyed. Some other kinds of earth will fall down in water or air; but whatever body has this property, and also effervesces with acids, the farmer may conclude to be marle.

It will be of use to the farmers, not only to distinguish marle from other bodies, but likewise to discover, before they make use of it, what proportion any marle contains of calcareous earth, clay, and sand. This he may readily do, in the following manner.

Having dried and powdered the marle to be examined, pour upon any weight of it a small quantity of water. To this mixture, well shaken, add a little of the acid of sea salt, and when the consequent effervescence is over, add a little more of the acid. Repeat this addition at proper intervals, till no more effervescence ensues. Then throw the whole, with an equal or greater proportion of water, into a filter of brown paper, whereof the weight is known. When all the fluid parts have passed through, fill up the filter, again and again, with warm water. By this means the dissolved particles of calcareous earth, adhering to the residue, or entangled in the pores of the paper, will be washed away, and nothing but what is really unsoluble will remain in the filter. This residuum, with the filter, is then to be completely dried, and weighed: the difference betwixt its weight, and the original weight of the filter, gives you the weight of the unsoluble parts (the clay and sand) contained in the marle under examination. This being known, the proportion of calcareous earth therein is evident.

Here it is to be noted, that a vegetable acid, as vinegar, is not proper for this experiment; because all the calcareous earth in marle, cannot usually be extracted by it: for after the usual filtration, the residuum effervesces with acids. Neither is the vitriolic acid proper for this use: for though it effervesces with all marles, it does not dissolve their calcareous earths, but only forms with them a whitish coagulum, which will not pass through the filter. But all the other mineral acids may be employed to equal advantage; as the acid of sea-salt, nitro, &c.

The proportions of clay and sand, contained in the residuum, or unsoluble parts of this process, are discovered by

what is called elutriation, which is thus performed. Having weighed this dry residuum, mix and shake it well, with a sufficient quantity of water: and after allowing a little time for the grosser parts to subside, let the water, with the finest part of the clay suspended in it, be gently poured off; then add more water to the remainder, and after sufficient mixture and subsidence, pour off that likewise. In the same manner repeat this operation, again and again, till the water comes off perfectly pure; the substance that then remains is sand, mixed, perhaps, with some flakes of talc: and whatever this substance wants of the weight of the residuum employed, is the weight of pure clay, carried away by the water, in this process of elutriation.

This experiment, for discovering what proportion is contained in marle, of calcareous earth, clay, and sand, is not proposed as a matter of mere curiosity, but that the farmer, who will take the small trouble of examining marle in this manner, may thereby know for which of his lands the different sorts of marle is most proper: for though marles will fertilise all sorts of land, yet not equally. Those marles where he finds the largest proportion of clay are most proper to lay upon his sandy, light land; and those that contain the most sand, for his strong land: the calcareous earth fertilises both sorts of land, the light and strong.

It has been a common opinion, that all rich manures were so, because they contained much vegetable food. Hence marle was thought to contain a large proportion of nitre, or other salts; but when it was found, that it contained no salts, it was then supposed, that it attracted them from the air; but this is now discovered to be also an error: for from many accurate experiments upon all the marles, that have been long exposed to the air, no salts of any kind have been found in any of them, except in one experiment made by Dr. Ainslie, who found some muriatic salt in one bed of marle, that had been exposed for ages to the open air; but none in any other bed of marle, that had the same exposure.

It is singular that no vestiges of this or any salt appeared upon any of the beds of marle, but one, and this one had nothing peculiar, either in its composition or situation. It differed from the rest in this only, it was possessed of a greater degree of moisture; but whatever was the cause of this singular instance, it can be no foundation of the opinion of marle attracting salts from the air. And marles are found to produce the most remarkable effects on light exhausted soils, where they can find little or nothing proper for furthering a nitrous process, or the production of any other salt hitherto known.

Stone and slate marles, being harder than clay marle, are longer in dissolving; and therefore a larger quantity of them may be laid upon land than of clay-marle, whereof about thirty cart-loads has been recommended as a proper quantity to be laid upon an acre; of the harder sorts of marle somewhat more, but of shell-marle ten or twelve loads; this being of a more open texture, and sudden effect, much of it laid on at once would make the crops too luxuriant. And in general it is most advisable in laying on marle, to lay it rather sparingly at first, till the effects of it are seen, as it is easy to add more afterwards.

MARSHY LANDS, a sort of pasture or grazing grounds, lying near the sea, rivers, or fens.

As to lands lying near rivers, the great improvement of them is their being overflowed, which brings the soil of the uplands upon them, so that they need no other mending, though kept constantly mowed. The great inconveniency of these lands is their being subject to floods, which high hills near the sides of rivers, and the long course of them, bespeak to be frequent: and, though the richest land generally lies near such rivers, yet there is the greatest danger of the crops being spoiled, especially when they are not inclosed, and therefore cannot be fed with cattle. This, when feeding bears any thing of a price, would be the very best way of managing these uncertain lands; and inclosing them would be highly beneficial on this account. *Mortimer's Husbandry*.

The marsh-lands in Lincolnshire, and many other parts of England, produce a sort of grass, which feed sheep in a better manner than that of almost any other land, in regard to their size, and the quantity of wool. The sheep about Grimsby, and some other places in this county, produce such lustrous wool, or, as they call it, wool of so large a staple, that three or four fleeces usually make a tod of twenty-eight pounds weight. Several hundred loads of this

this wool are yearly carried from these places to Norfolk, Suffolk, and other parts of the kingdom, for the cloth manufactures. They send this in large packs, which they call pockets, each containing about five and twenty hundred weight. *Philos. Trans. Numb. 223.*

When marsh lands lie flat, it is necessary for the owner to keep all the water he can from them. The sea-water in particular is to be kept from them as much as possible; and this is usually done at a very great expence, by high banks and walls.

Two things greatly wanting in these lands, in general, are good shelter for the cattle, and fresh water. The careful farmer may, however, in a great measure obviate these by digging in proper places, large ponds to receive the rain water, and by planting trees and hedges in certain places towards the sea, where they may not only afford shelter for the cattle, but keep off the sea breezes, which often will cut off the tops of all the grass in these places, and make it look as if mowed.

These lands fatten cattle the soonest of any, and they preserve sheep from the rot. It would be of great advantage to them, if there were raised, in the middle of every large marsh, banks of earth in a cross, or in the form of two semi-circles, and these planted with trees; these would serve as a shelter for cattle, let the wind blow from what quarter it would, and would soon repay the expence of making.

There are, in different parts of England, very large quantities of land upon the sea-coasts that would be worth taking in, though no one has yet thought of doing it. The coasts about Boston, Spalding, and many other parts of Lincolnshire, give frequent instances of this, where the sea falls from the land, so that on the outside of the sea walls, on the owse, where every tide the salt water comes, there grows a great deal of good grass, and the owse is firm to ride upon when the water is upon it.

This owse, when taken in, hardly sinks any thing at all, and they dig the walls from the outside of it, all the earth they are made of being taken from thence, and the sea, in a few tides, filling it up again: and though the sea, at high water, comes only to the foot of the bank, yet once in a year or two, some extraordinary tides go over the banks, though they are ten feet high. These banks are fifty feet broad at the bottom, and three feet at the top; and the common price of making them is three shillings a pole, the earth being all carried in wheel-barrows, and face towards the sea, where the greatest slope is, being turfed. *Mortimer's Husbandry. See the article DRAINING.*

MATFELLON. See BLUE BOTTLE.

MAY-WEED, a wild species of chamomile, a trailing perennial plant, which puts out from its branches as they lie on the ground. By this means, and by scattering its seeds long before the corn is ripe, it spreads and multiplies greatly. It flowers in May, and thence has acquired the name of May-weed.

The means of extirpating it are, summer fallows, repeated good harrowing, and burning the collected roots, as before directed, in similar cases, or, which will be found still more effectual, the frequent hoeings practised in the New Husbandry. What escapes these clearings should be very carefully pulled up by hand; for the common weeding-hook will not go deep enough to take out the whole of the long slender tap root of this plant, of which every remaining bit that has a knot in it will produce new shoots. Nor ought the farmer to regret this small additional expence, to get rid of one of the most fatal enemies his corn can have. Mr. Little assures us, that as good a crop of wheat as one would wish to see all the winter time, was, to his knowledge, so destroyed by the coming up of May-weeds and poppies in the spring and summer, that it did not at last yield so much as the seed.

MEAD, a liquor made of honey, and held in great estimation by most of the northern nations, but perhaps not esteemed here so much as it might deserve, if due care was taken to prepare it properly.

All the writers who have hitherto treated of this subject, have given into a capital error with regard to the strength of this liquor, by directing too great a proportion of honey to be dissolved in the water. The usual practice of making it so strong as to bear an egg, is very wrong. The liquor is thereby rendered a meer stum, and this bad quality is still increased by the long boiling generally practised. It is scarcely possible to procure honey so pure, but that some bee-bread, wax, or other substance, is mixed with

it; and this cannot be perfectly separated from it, so far, as I know, but by boiling. On this account the boiling of mead seems indisputably necessary. In order the more effectually to separate these impurities from the liquor, it will be advisable to mix some whites of eggs with it before it is put on the fire, and it will be particularly necessary to skim off the thick scum that rises, the moment the liquor begins to boil; and this must be attentively continued so long as it boils. The only intention of boiling being here to separate the impurities, and to make a perfect union of the water and the honey, both which purposes are very soon obtained, it evidently appears, that the boiling need be of but very short duration. This becomes here more particularly necessary, because the liquor will be the less disposed to ferment kindly, the longer the boiling has been continued. It is perhaps owing to the single article of long boiling, that mead has hitherto lain under so great discredit; because it then never fermented sufficiently to take off its luscious sweetness; whereas, had it undergone a due fermentation, that sweetness would have gone off, and the mead would have attained a fine racy flavour.

Some notable housewives have added hops to their mead. This helps to take off its sweetness, and, as the bitterness of the hop goes off, gives it a pleasant flavour. A ferment is here, as in all liquors that are boiled, generally wanted to bring on a perfect fermentation: but as the least taint in the ferment is communicated to the whole liquor, particular care should be taken that it be very sweet and good. Mead, judiciously managed on these principles, will keep for years, and be improved by age. The racking, fining, &c. of this liquor, are the same as those of other white wines.

MEADOW, a general name for pasture or grass-lands, annually mown for hay; but is more particularly applied to lands which are so low as to be too moist for cattle to graze upon them in winter, without breaking the sward.

Meadows, being generally enriched with the fine mould washed down from the adjacent rising grounds, are usually of a good soil, and seldom require any other improvement, than the removing of temporary imperfections. But they may likewise be of such a nature as to stand in need of a more particular treatment: as is the case when their surface is a mossy, loose earth, or when it is of a binding or clayey quality.

If, through long neglect, a coarse strong grass, rushes, or other bushy plants, be suffered to remain upon the ground till they rot there, they will, in some years, form a loose, spongy substance, somewhat resembling moss. In this case, the first necessary step is to pare off and burn that loose surface, or at least so much of it as to enable the plough afterwards to reach the better soil underneath. The manner of doing this has already been explained so very amply, that it will be sufficient to add here, that this loose upper earth must be so strengthened as to afford sufficient stability to the roots of whatever plants are sown on it, by mixing it well, either with the better soil underneath, or with marle, clay, or rich loam, brought to it from the neighbouring grounds, or with the composts before directed for this purpose.

If the soil is clay, or a strong binding earth, the treatment of it is much the same, whether it be meadow or upland pasture. Such soils, by retaining water in every hollow place, become what the farmers call sour, and produce a coarse grass, composed, as Mr. Miller observes, of bad weeds, of which the several sorts of docks make no small share. Although many of the meadows produce a great burden of what the country people call hay, yet this is fit only for such cattle as, by hard labour and hunger, are driven to eat it: for horses which have been accustomed to feed on good hay, will almost starve rather than touch this. A plain proof of its being disagreeable to all cattle, is, that when they are turned in, after it has been mowed, we often see the ground covered with rank weeds, which they will not meddle with.

When a pasture is in the state above described, if there is a sufficient depth of soil to admit of it, the surface should be pared off, and burnt: and as such places are usually over-run with ant-hills, these should also be burnt; after which, by the addition of proper manure, and by the help of deep plowing, the land should be brought into fine tilth. The deeper this improvement goes, the deeper and more lasting will the grass be. We have been informed of a particular instance of the good effects of this method, by

which the gentlemen who practised it had grafs which continued for years in a strong state of vegetation, and was constantly near a month forwarder than that of his neighbours, whose soil and situation were exactly the same.

Let not any one be deterred by the expence attending this improvement for the crops of grain and other plants taken while the soil is thus preparing, will nearly repay all the charges, and the ground will afterwards yield much more plentiful crops of grafs; at least for a number of years. But as clayey lands require more frequent and more thorough repairs than other soils, the returns of tillage proposed by Camillo Tarello will be the most proper means of managing them.

He would have farmers divide their pastures in four parts, keep one of these parts under grain or pulse, during five years, and at the expiration of that time lay it down to grafs as before; and so proceed with every other part. He proposes, that the first breaking up should be by paring and burning, and thorough ploughing. But if we may differ from him in opinion, we think it is needless to keep the ground so many years in tillage, unless this should suit the husbandman's convenience for the culture of particular plants. In this case the pasture may be divided into five or six parts. After each part has thus been in tillage, Tarello advises breaking up again the spot first began with: though not by burning now, but only by ploughing, in order to sow it as before. "This, says he, will be profitable to the husbandman, and improve the pasture, will benefit the husbandman, because he will thereby raise a greater quantity of corn; and it will do good to the pastures, because nothing is more serviceable to them, than this renewal of their surface, as is attested by Columella. Let not the husbandman imagine that he will have less hay when only three fourths of his usual extent of land are under grafs: for, in fact, it is not the quantity of the land, but the care which is taken of it, that gives plenty of hay."

When a soil of this kind is laid down for meadow, great care should be taken to slope it down gently, from the middle, in such manner that no water may rest on any part of it. If the extent is large, small ditches should intersect the meadow into as many divisions as shall be necessary to form a sufficient drain for the waste water, and the spaces between these ditches may be gently raised. In an upland pasture on such a soil, ridges should be raised inclining a little from the horizontal, that the furrows may be so many drains, as before directed in the ploughing of such soils, to prevent their becoming spewy or wet: for as the rain cannot descend beyond the clay, it will glide along it, till, collected in such quantities as to form a small stream, it issues forth at the surface, usually loaded with some mineral quality imbibed from the earth underneath.

When the soil is a rich or light loam, the plough will not be so necessary; as such meadows or pastures may be repaired by the means which will be pointed out in the directions hereafter given for the improvement of the meadows already laid down to grafs. See the article GRASS and PASTURE.

Black, rich mould, requires but a moderate quantity of water: just sufficient to give action to the fertilising particles it contains. The watering here should be frequently repeated, rather than long continued.

It is a general rule, that sandy or gravelly soils require watering the most of any: because whatever moisture they receive, sinks through them too speedily. But it may be doubted, whether this very reason for watering them be not one of the greatest of objections against their being watered, at least so much as is generally directed: for the water not only passes rapidly through these soils, but it may carry down with it through the sand or gravel, the finer and richer particles of the shallow mould usually found upon such soils, and thereby rather impoverish their surface. It would therefore seem advisable, to let water in upon such soils only occasionally, to refresh the verdure, when their surface is too dry: and too give it a pretty quick current, that it may reach to a greater extent of surface: for if it runs slow, it sinks too fast.

It is a question whether pastures newly laid down to grafs, after having been arable land, ought to be watered at all during the first year. The judicious author of one of the ingenious dissertations in the Memoirs of the Berne Society consulted on this subject an intelligent farmer, who had experienced the effects of watering, and of not water-

ing, these new pastures, as some call them, and was answered, that they had yielded the greatest quantity of grafs the first year when they had been watered, but that the crops had always dwindled the succeeding years: whereas those that were left dry till autumn, and then only begun to be watered had made ample amends during the following years, for the scantiness of their produce in the first. This husbandman was therefore of opinion, that it is best not to water these meadows before the autumn; and he added a farther very sensible reason, namely, that as these new meadows still retain some portion of the manure laid upon the land the year before, when it was sowed with corn, the letting in of water upon them, while the mould is yet extremely loose and light, will be apt to carry off those rich remains of manure, which will otherwise incorporate with the soil, as it acquires more consistence.

A very wrong custom which prevails among our farmers, in general, with respect to low meadows, is, that of flowing them during the whole winter. The roots of all the sweetest kinds of grasses are thereby destroyed, and only such left as are natives of marshes, which are coarse and sour, and which no cattle will eat.

The method which Mr. Miller proposes for the management of these meadows, is never to flow them till the middle or latter end of March, excepting once or twice in the winter, when such floods happen, as bring down a great deal of soil from the upper lands; for then it will be of great service to let such water in upon the meadows, that the soil may settle there; but the sooner the wet is drained off after this is lodged, the greater will be the benefit done to the meadows. By letting on the water frequently, from the end of March to the middle of May, the growth of the grafs will be greatly assisted, and there will not then be any danger of destroying its roots.

River water, which is universally acknowledged to be the best for this purpose, cannot be so beneficial when the stream overflows its banks, and runs rapidly over the pastures, as when its course is slow; and still much less than when it stagnates. It therefore is adviseable to fence in every meadow liable to be thus overflowed, in such manner that it cannot be flooded, but at the owner's pleasure, by opening proper sluices. But as the produce of many meadows will not bear this expence, the proprietor, or farmer, should if possible, prevent the too hasty current of the water, by raising at their upper end, or wherever else it may be necessary, such fences as shall render the water which flows sidewise upon the meadow, rather a back, or standing water. Great advantages will arise therefrom. The finer mould will no longer be carried away by the strong current of the river, which, instead of robbing the soil, will then deposit a rich sediment, and thereby greatly fertilize the land.

The water of mineral springs should not by any means be brought upon pastures; because they are either destructive of grafs, or produce only a very harsh coarse kind of it.

We shall close this subject with the following remarks made by the judicious author of one of the before-mentioned dissertations in the Memoirs of the Berne Society, and which deserve the serious attention of every husbandman who would water his pastures with due care.

"Many people imagine, that the whole art of watering meadows consists in making good channels, and in opening and shutting the sluices at proper times. But this is not enough: for so long as the water flows in a meadow, the farmer should visit all his channels once or twice a day, with a shovel, hoe, or three-grained fork in his hand, and examine carefully whether any of them want cleansing or repairing. Sometimes he will find a channel choked with slime; in other places he will see the water spread too far, or not far enough; and in others again he will observe it not rise high enough to overflow its channel, so that the neighbouring ground is not watered at all. He will immediately endeavour to remedy these defects, according to the exigency of the case, whether by clearing away the muddy slime, heightening the banks of the channel, lowering them, giving a freer current to the water in some places, and checking its course in others, according to the nature of the soil: or by cutting new channels in some places, and laying sods or sluices across others, to divert the stream from such parts as are sufficiently moist, and turn it to others which want watering: for it very frequently happens that, even in the same meadow, though not a large one, there are very different soils, each of which requires the

the assistance of water, but in very different degrees. In short, the careful husbandman will not ever visit his pastures without noticing in them things which may be altered and amended."

The farmer who has improved his meadows according to the foregoing directions, may expect abundant recompence in plentiful crops of grass.

When grass is to be fed off, it should not be permitted to stand till it grows high, because the cattle will then trample under foot great part of it, which they afterwards will not eat. The prudent husbandman will also vary the kinds of cattle fed upon it. See the article HAY.

Meadows that are often mowed for hay, are thereby so much impoverished, that unless they are of an extraordinary rich soil, it is necessary to refresh them frequently with manure, which is commonly done by spreading the manure upon the land in the autumn or spring. M. de Chateaufieux invented a machine with three sharp coulters for cutting the land about 6 or 7 inches deep, that the manure laid upon it, might be washed into the incisions made by the coulters, which also cutting the old roots of the grass, many new roots were produced, and made a very great improvement, particularly, where the meadows were hide-bound, or over-run with moss; he called this instrument a cutting plough.

Mr. Wynn Baker added two coulters, and named it a *scarificator*, and not a plough, because, as he rightly observes, a plough is an instrument that raises and turns a furrow, but the *scarificator* does not; for it only makes parallel incisions in the surface, at about three or four inches distance one from another, but does not raise or turn the land.

This is a very useful instrument for the purpose of improving both meadows and pastures, which it does by cutting only, and without manure; but when the land is also manured at the same time, the improvement is very remarkable, encreasing the crops to a great degree, and also improving the quality of the grass; as has been experienced in several places in England and Ireland.

It is farther remarkable, and has been proved in practice, that if the land is first scarified, and then manured, the improvement is greater than scarifying the land after laying on the manure.

Dung is not so proper for this use, as compost beaten small; but ashes or dry powdered manure is best: for that is soon washed by rain into the traces made by the coulters.

The *scarificator* does not work steady in very stony land, the stones being apt to throw it out of its work.—In that sort of land, the spikey roller may be two or three times run over it; which if done when the land is moist with rain, the spikes will break the turf, and if also manured, will make a considerable improvement: though not so much as when scarified, because that goes deeper, and cuts the roots of the grass, by which they are multiplied.

It is an advantage, in this method of improvement, that a much less quantity of manure is necessary, than in the usual way, of spreading it all over the land without scarifying it.

MEADOW-FOX-TAIL GRASS, the *alopecurus pratensis*, Mr. Young, in his Annals of Agriculture, gives the following account of this grass, in a letter from his friend:

"In the month of June, 1786, I collected a small quantity of the seeds of the *alopecurus pratensis*, from a pasture of mine near St. Alban's, containing, by measure, seven pecks; with this, in March, 1787, I laid down a small field in this place, of three roods; the field had been a hop-ground, the soil excellent, and the seeds were sown (contrary to the usual method) without a crop of corn; with the grass seeds I sowed six pounds of the white or Dutch clover: in the course of three weeks the young grass made its appearance, and continued to grow with great vigour during the summer, and though, from the small quantity of the seed, it did not cover the ground till towards the end of autumn, yet I was able to mow it once, and the produce, inconsiderable as it was, proved excellent food to my horses; I cautiously rooted out the perennial weeds, and by the beginning of winter the ground was so completely overspread, as to wear the appearance of an old pasture. In the spring, 1788, the grass grew rapidly, and at so early a period as the first week in May, was in full ear; by the 14th of which month I might have mown it for hay; my object, however, was to collect the seed for a future, and more enlarged experiment, so that I suffered it to remain till the 27th, when the ears were reaped precisely after the manner of wheat, and carted home. The next

day the stubble (as I may call it), with the bottom of Dutch clover, was mown, and on the 3d of June I housed one ton of hay from the three roods; the seeds, on threshing, amounted to forty bushels. I now proceeded to lay down a field of seven acres (the soil a good earth, neither wet nor over dry) in the same manner as the former, and after the rate of four bushels per acre of the grass seeds, together with eight pounds per acre of the *trifolium repens*; this was effected on the 3d of July, 1788. The succeeding autumn proved moist, and favourable to vegetation, so that the grass and clover made so rapid a progress as to enable me to turn out, on the 8th of October, ten lean Scots, which remained constantly day and night, and ten horses at night only, for the space of three weeks. The great severity of last winter had not the smallest visible effect on the colours, and did not entirely check the vegetation of the grass; this degree of hardiness I must consider as a circumstance greatly in its favour, as other grasses seemed injured, especially the *poa trivialis* (rough stalked meadow grass), which appeared weak, discoloured, and in some places I observed that the blade had perished.

"From the unusual backwardness of the last spring, the grass was somewhat later than the preceding year, but with the clover was in perfect forwardness, early in June: observing a particular luxuriance in the latter plant, I determined to let the whole stand for a crop of its seed, being aware that, by so doing, I should leave time sufficient for the seeds of the grass to sow themselves, to the future benefit of the field; accordingly it was suffered to remain uncut till the 1st of August, at which time, the heads of the Dutch clover appearing perfectly ripe, the field was mown, and on the 6th of the same month I carted 11 tons of the most excellent hay that could be produced; the crop of clover seed will amount to 16 bushels. This field is now in the completest state, and leaves me every reasonable hope of its becoming a highly profitable pasture, preferable to what I might have acquired from the usual, but uncertain, method of laying down lands to grass, nor can I doubt that it will fully recompence the attention and perseverance I have bestowed on it.

"From these and other observations, made by me, on this grass, I am induced to make the following remarks:

"The *alopecurus pratensis* is likely to prove very useful to its cultivators, from its earliness, it being generally the second to flower of those grasses most esteemed for agricultural purposes, and, indeed I have not unfrequently remarked it to precede the *anthoxanthum odoratum*, which is usually the first.

"It is eaten, readily and with relish, by horses, cows, sheep, and swine.

"It produces a great burthen of most excellent hay, which, from its being so early in a fit state for mowing, leaves ample time for the ground to bring a plentiful after-crop to perfection.

"This circumstance, and its being considerably earlier than the *lolium perenne* (rye-grass), was the reason of my selecting it as a fit object of experiment.

"Though to a common observer, this grass, from the breadth and quantity of its foliage, might seem somewhat coarse, yet, on examination, it will be found by no means so as to prejudice the hay from it, or disgust the cattle when depasturing.

"The *alopecurus pratensis* is certainly subject to the depredations of a small maggot, which lodging itself in the seed vessel, destroys the seed; this has occasioned a surmise, that the grass in question could not be generally cultivated, but I presume I may, from the above experiments, venture to assert the mischief not to be so great as to exclude this useful grass from introduction on the most enlarged scale of agricultural practice.

"This grass delights mostly in soils which are inclinable to moisture, yet not so entirely but it will succeed perfectly on good uplands which are not absolutely acid.

"Upon the whole it may be reasonably concluded, that the culture of the *alopecurus pratensis*, would be no unworthy object of the farmer's attention; it is greatly superior to his *lolium perenne*, in being earlier ripe; it seems also more nutritious from the form and greater luxuriance of its foliage. Indeed its generally good qualities have been so strictly attended to by me for three years past, as to induce me fully to agree with the ingenious Dr. Pulteney, who says, that the *alopecurus pratensis* is amongst the most grateful of all grasses to cattle.

"I have sent, here with, 4 bushels of the seeds of the grass, grown

grown this year, of which I beg your acceptance, and if at any future time you should be led towards the Patrician Pile, close to which I live, I shall be made happy in shewing you the field in question, as well as any other attention in my power.

" Since writing the above, I find it in my power to present you with the inclosed small specimens of the seeds of the five other grasses; I have cultivated them for some time past in my garden, for amusement; they are all excellent, and are to be met with in many of the better sorts of pastures in Great Britain."

Mr. Young also inserts the following letter, in his *Annals of Agriculture*, vol. xvi. written by the same person.

" I took the liberty, some time ago, of troubling you with a few slight observations on the seeming propriety of attempting the particular selection, and separate culture, of the most useful sorts of our indigenous grasses; and at the same time, I entered into the detail of several experiments made by me, on the *alopecurus pratensis*, or meadow fox-tail grass, to the culture of which, on account of its peculiar earliness, and ample produce, I had given particular attention.

" These circumstances appear in No. 71. of your *Annals of Agriculture*.

" As more than a year and a half is now elapsed since the above communications, you may possibly not deem it altogether superfluous on my part, to resume the subject more at large; in order to lay before you the progressive success of my experiments and observations on this plant; which may serve to ascertain, with some degree of precision, how far the practical farmers (upon the supposition that by the industry of individuals, he is enabled to procure the pure seeds of the most useful grasses) may proceed to adopt the theoretical, yet natural system of Stillingfleet, with safety and effect.

" On referring to my preceding letter you will see, that my field laid down with the *alopecurus pratensis*, was mown on the 1st of August 1789, and that its produce was 11 ton of hay; the reason of its being mown so late is there fully stated, and the effects fully answered my expectations; for by the fully ripened seeds sowing themselves, the field improved in fulness of plant, whilst the sale of 16 bushels of the white clover seed produced 40l. The seed was very good, but a quantity raised by me last year was of so fine a quality, that my seedsmen informed me it was greatly superior to several cargoes just then arrived from Holland. Why are we to be almost entirely indebted to foreigners for a plant so generally indigenous with us? Several farmers in my neighbourhood have lately cultivated the *trifolium repens* as well as myself; and have remarked, that the wheats sown after it, wear a more promising appearance than those after the red clover, this is important, for if it becomes an established fact, it will be an additional inducement in favour of its culture, for the sake of instituting that change in the rotation of crops, so frequently insisted upon by many enlightened farmers.

" I shall now proceed to state to you the subsequent management and produce of this field.

" The lay was shut up on the 6th of August 1789, as soon as the above 11 tons of hay were carted off, in which state it remained until the 13th of October following, when nine large bullocks (purchased at Braintree and Woolpit fairs in the autumn of the preceding year, and which were at this time nearly fat) were turned into it, where they remained in the most plentiful after-feed until the 28th of that month; they were succeeded by five cows, which were also in the field 15 days, and four horses 11 nights only, and on the 27th of November the lay was cleared and finally shut up for the winter.

" In the spring 1790, the field was bush-harrowed and rolled; the grass had by this time acquired a greater strength of vegetation than in the former year, and assumed a very promising appearance at an early period, and being in high perfection in the second week in June, was mown on the 11th of that month; on the 17th of which the produce, amounting to 14 tons, was carted. The hay, both in flavour and colour, was of the most excellent quality; and the weather proving favourable, the whole was stacked without damage. Soon after this the field was dressed with a rich compost of farm-yard dung, rotten leaves, and some quantity of coal ashes, at the rate of 20 loads (of three horses to each) per acre, which being carefully and evenly spread, the lay was on the 26th of June shut up for the second crop.

" The grass made a rapid progress through the months of July and August, and on the 3d of September was mown, for the second time, and with the same success of weather

attending as on the first crop, seven tons and a half were carted; but here I must observe, it was not without reluctance that I permitted the field to be mown a second time, because, although the hay was well made, and as well got in, yet, even with these advantages, the inferior quality of rouen hay, at this season of the year, is well known to every farmer, and if the weather proves unfavourable during the making, though but for a very few hours, it would be damaged so as to become of little or no value. The hazard, therefore, attending this crop is great, whilst the produce at best can be deemed only of an inferior quality. On the other hand, the luxuriance of autumnal grass is the farmer's pride as well as profit, is of the greatest use to cattle, and best adapted to the purposes of pasturage. Nothing, therefore, could justify the above measure, but the satisfaction of ascertaining with accuracy the quantity of produce and the effects of a second crop on this particular grass; in respect to the former, the produce may fairly be deemed ample; as to the latter, the grass seemed to spring up after the second mowing with equal rapidity as after the first; indeed, this grass seems to me to possess a quality not common to many others, that of sustaining scarcely any check from the wound of the scythe.

" On the 11th of September, 1790, the field was again shut up, in expectation of the eventual advantage to result from the after-feed, which might yet arise before the winter. In this we were not entirely disappointed, for on the 5th of November eight Scots (purchased October 3d at Braintree) were turned in and remained fourteen days, which with eight horses six nights, and four horses eleven nights, conclude the produce of this field to the 2d of December last, on which day it was finally cleared from the stock.

" Concerning the merits of this grass, I am well convinced it will be found to answer every reasonable expectation from it, on soils adapted to its growth, either as hay or pasture; cattle relish the former entirely, and the bare state of the field on the 3d of December last, clearly shewed the avidity with which it had been cropped. In my experiments I have purposely omitted stating a few days during which sheep were occasionally turned into the lay, because the time was but short; but they depastured as freely as the larger cattle, and I have had sufficient proofs upon another pasture formed by me of this grass, that it is highly grateful to them.

" In forming this lay, my wish was to have sown it with a mixture of grass seeds, such as I was sure were suitable to the soil; but the absolute impracticability of procuring them pure, induced me to give up all thoughts of so desirable a combination, and to content myself with the seeds of this grass which I had separately cultivated. I trust, however, the time will arrive when it will be possible for the farmer to procure the seeds of the best grasses in quantities sufficient to enable him to form his combination of them upon just principles; first, by adapting the grasses to the soil intended to be sown; secondly, by selecting, as much as may be, such grasses as produce the greatest quantity of hay or pasture, ripen nearly at the same time, and which possess the greatest degree of perennity. By these means, the land will yield the greatest possible produce of the grasses, will establish themselves so as to extirpate others of a lesser degree of durability than themselves; for it may, I presume, be asserted, that a plant introduced on land of a nature to encourage its growth, will flourish in it, in proportion to its degree of perennity, whereby it is endowed with powers of establishing itself fully, and at the same time of extirpating all neighbourhood annuals, biennials, as well as such perennials as are of less degree than itself; thus it has appeared to me in practice, and this may serve to answer an objection made to the theory of Stillingfleet, that the natural grasses, or such as are the spontaneous produce of the soil, will in time overpower and destroy those imported, and thus defeat the labour and hopes of the cultivator.

" The *alopecurus pratensis* appears to me, from experience, to be intended by nature for moist situations, and though it will succeed well in good upland soils, that are not absolutely arid or bound, yet it will be found greatly more productive in the former situations: but to attempt the culture of this grass on mountainous places or on dry sands would be to no purpose.

" A gentleman, highly conversant in agricultural subjects, has suggested to me that it will be scarcely possible for this field to continue to produce so large a crop as that of 1789, and that perhaps one third of this great crop must be laid to the score of fresh soil; for that it is observable, that when grasses or any other plant have been long continued in one spot, they cease to be equally productive as when first sown or

or planted: with this idea I shall readily concur, and candour must induce me to suspend any final opinion on this subject, until a course of years shall enable me to speak with perfect conviction. Perhaps in no science is it so difficult to form experiments with certainty and effect as in agriculture; a combination of circumstances seems to step in between the cultivator and his experiment: and though he be strictly accurate in his report, a difference of soil, situation, and most of all, of seasons, will often prevent the establishment of his experiments into general principles.

"This however, far from deterring, should stimulate the industrious and practical agriculturist to persevere in his remarks, with the laudable hope that a due course of time, and strict attention, united to a frequent repetition of his experiments, may give a degree of stability to them. By this he will enjoy the satisfaction of having contributed something in his day, to the improvement of a science, at once delightful to himself and highly beneficial to the public at large.

I have lately cultivated another grass, the *festuca pratensis*, or meadow fescue grass, with some success; it is much relished by cattle, and makes excellent hay: it is somewhat later than the *alopecurus pratensis*, but possesses qualities little inferior to that grass. If it is agreeable to you, I will trouble you with some remarks upon it at a future period."

MEADOWS. See WATERING MEADOWS.

MELCERIDES, in *Horses*, tumours so called, from their resemblance to an honey-comb.

They attack the joints and send forth a gluey matter like honey.

The way to cure them, is to burn them with red hot irons, in order to bring away all the matter, and to heal the ulcers with wax melted and hogs-grease, and to wash them with cold, but rather with sea-water, if it can be got. Some recommend the burning them with brass-plates.

MELILOT, a plant of the trefoil kind, and grows in such abundance among the corn in many parts of England, particularly in Cambridgeshire, as to be a most troublesome weed; for it is hardly possible to separate it from the corn in reaping, so that they are housed together, and the seeds of the melilot, which ripen about the same time as the corn, are threshed out with it; after which, they being likewise heavy, it is very difficult to separate them. If but a few of these seeds are ground with the corn, they will spoil the flour; for the bread, or whatever else is made with it, will have a strong taste and smell like melilot plaster. The roots of this plant are strong and woody, and from them spring out several stalks, which rise from two to four feet high, according to the goodness of the land. These stalks branch out, and are garnished with trifoliate leaves, having oval sawed lobes of a deep green colour. The flowers are produced in long slender spikes, which spring from the wings of the stalks. They are of a bright yellow, shaped like the other butterfly flowers, and are succeeded by naked seeds, which ripen in August.

MELLIT, a distemper in a horse, being a dry scab growing upon the heels of his fore-feet, which may be cured after the following manner:

Take common honey, half a pint; black soap a quarter of a pound: mingle them well together, adding four or five spoonfuls of vinegar, and the same quantity of allum, finely powdered, soaked in a hen's egg, with two spoonfuls of fine flour. Let all be well mixed together, clip away the hair from the part affected, and apply it to the sore, after the manner of a plaster, and let it remain five days.

Then take it off, and having washed all the leg, foot, and sore, with broth of powdered beef, rope up his legs with thumbands of soft hay, wetted in the same liquor, and it will effect a cure.

Whenever you dress the sore, do not omit the pulling off the scab, or any crusty substance that may be upon the sore, and also to wash it clean.

MESTIN-CORN, wheat and rye mixed together.

MET, a strike, or four pecks.

METEYARD, or METERWARD, a staff of a certain length for taking measures.

MICE. See VERMIN.

MIDDING, a dunghill.

MIDGE, a gnat.

MILDEW, a distemper very destructive to corn.

"This distemper, says M. Duhamel, attacks the blades and stems of corn, which it covers with a powder of the colour of rust of iron, when at the height of their vegetation. This substance does not adhere strongly to the blades; for I have seen the hair of white spaniels full of this powder, after they have run through a field attacked with this disease. It is likewise known, that if the infected wheat is washed by a plentiful rain, the rust disappears almost entirely, and the grain suffers little from it. The French give it the name of rust, from the colour of the powder, and it seems to be the same distemper which the Roman writers call *rubigo*.

"The cause of this distemper is usually imputed to dry, gloomy weather, happening while the corn is at the height of its vegetation; and in effect I have many times observed, that when a hot sun has succeeded such dry, hazy weather, corn was rusted within a few days after.

"This distemper is not common in clear, dry, hot years: but when the spring is wet, the finest fields of wheat run great hazard of being destroyed by the mildew, which generally appears upon the breaking out of the sun in the morning, after close and sultry weather, during which there has not been any dew. The rusty powder then gathers upon the blades in such quantities as to cover the earth two feet around. M. de Chateauvieux cut off the mildewed blades, and found the trial answer: the same plants produced new blades, and throve much better than those on which this operation had not been performed: but this cannot be done except when the corn is very young.

"This distemper is very fatal; for the finest wheat is suddenly brought almost to nothing, when it is entirely attacked with it.

"If it attacks the plants while they are young, and before their stems begin to rise, the mischief is sometimes not very great, provided there comes on a season favourable to their farther growth. In this case, they are only weakened, as if they had been fed or mowed. They shoot out anew, and produce ears: though their straw is shorter, and those ears are smaller, than they would otherwise have been. But if both blades and stalks are mildewed at the same time, the farther growth of the plant is stopt, and the grain gets scarce any more nourishment; so that the crop is exceedingly diminished.

"This grievous distemper well deserves the serious attention of every inquirer into nature, who interests himself in the progress of agriculture; and I cannot too strongly exhort all such to endeavour to investigate its causes and remedies.

"Several authors have, very improperly, confounded this distemper with others to which corn is subject. M. Tillet imputes it to a sharpness in the air in dry, cloudy weather, which breaks the vessels interwoven with the substance of the blades and stem, and makes them discharge a thick oily juice, which, drying by degrees, is turned into that rusty powder. In effect, if we examine with a microscope, or only with a good magnifying-glass, plants of wheat, whose stems and leaves are covered with rust, we shall see distinctly small crevices in the places where this powder lies, and shall discern, from space to space, in the membrane of the plant, openings through which it seems probable that the juices, afterwards converted into this rusty powder, issues, and over which one may perceive some slight fragments of the membrane imperfectly covering those cracks and openings.

"In support of this opinion, M. Tillet quotes a memoir of M. de Rencéaume, published in the Transactions of the Academy of Sciences, on the extravasation of the nutritive juice of the walnut trees in Dauphiny: of the manna of Calabria, which is not a dew, but the extravasated juice of the leaves of a kind of ash; and what M. Muschenbroek relates in his Physical Essays of thick and oily juices which issue out at the excretory vessels of leaves, and stop there in the consistence of honey.

"However this may be, the rust of corn is the consequence of a distemper of which the first cause is not yet sufficiently known. It is a mistake to think, that the rust and mealy powder which may be seen on many plants are a collection of eggs laid there by insects, and that this is a source of other innumerable insects very fatal to vegetables. By admitting the extravasation of the nutritive juices, as the cause of these distempers, we shall conceive that the rust of corn, the honey-dew, the mealy-dew, and all the unctuous substances which are found upon gramineous

plants, depend on the quality of the juice concentrated in the plants, upon the outside of which it manifests itself by evaporation, and is converted sometimes into an impalpable powder, and sometimes into that thick substance which is red on garden-beans, of a rusty colour on all kinds of corn, greenish on the plumb-tree, yellowish on the ash, white on the larch-tree, &c.

"These observations and reflections still leave undoubtedly much room to wish for farther information.

They will, however, greatly help to point out the path to a careful observer, and ought to excite philosophers to exert themselves in a matter of so great importance to the public. We confess that we have tried to produce the same effects as the dry, hazy weather, which occasions the rust, by applying to the leaves of many plants, acid and corrosive liquors, to others alkaline or spirituous, and frequently such clammy glutinous substances as might stop the perspiration without hurting the texture of the plants: but none of these trials have produced any thing like rust. However, who can tell how far experiments may lead the judicious and attentive? Some little circumstances which may have escaped us, might perhaps, if duly remarked, have led us to the object of our search. The public welfare calls on all attentive observers to exert themselves on this very interesting subject.

"Count Ginanni, in a memoir printed in the *Journal Economique*, for October 1761, treats expressly of this distemper, and says, he has observed, with the help of a microscope, small worms lodged between the two membranes of the blades.

"If we had any certain knowledge of the causes of the rust, we should probably be enabled the more easily to find preservatives against it: but in the mean time it will be right to collect every observation made by lovers of agriculture; because they will certainly afford useful lights at one time or other.

"M. de Chateaufvieux observed, in the autumns of 1753 and 1754, that when the corn was rusted, the second crop of hay was so likewise. The grass turned from a fine green, to the ugly rusty colour of the corn: it was covered with the same kind of powder, and its quantity diminished sensibly every day; and as the whole of a field of corn is not usually affected at the same time, so this distemper extended only to some parts of the meadow.

"The cause of this distemper is undoubtedly the same in corn and in grass; but its effect is not exactly similar. It may destroy annual plants, such as corn, entirely; but in perennials, like grass, it destroys only the leaves or blades. May not the preservation of these last be owing to the taking off of those leaves or blades, when they are cut for hay? But this is only conjecture; for I own that I have not yet made any observation on this head.

"As the straw of smutty, mildewed, or rusted corn, and by the same rule, grass, in a similar condition, may possibly give diseases to cattle fed with it; it were to be wished, for the public good, that a parcel of fodder, the most infected with either of these distempers, should be set apart for the food of a certain number of beasts. If cows or oxen, for example, remain sound and healthy, after having been fed with this growth for two or three months, we may afterwards give it them with confidence and safety: but if, on the contrary, they are visibly disordered by it, the remedy is easy and at hand, by feeding them with good wholesome hay, which will carry off the disease then known to proceed from the bad quality of the food."

The air in England seldom is so dry as to exhale all the moisture of the glutinous exudations, and thereby convert them into the rusty powder above described. The extravasation of the sap seems to account for this distemper of plants in a much more rational manner, than the thick clammy dews which some of our authors speak of, as falling in close weather, stopping the perspiration of vegetables, and hindering their juices from ascending to nourish the flowers, &c.

Mr. Miller takes the true cause of the mildew's appearing most upon plants which are exposed to the east, to proceed from a dry temperature in the air when the wind blows from that point; in which case it stops the pores of plants, and prevents their perspiration, whereby their juices are concentered upon the surface of their leaves; and that concretion being of a sweetish nature, insects are incited thereto. Those insects, finding their proper nutriment, deposit their eggs, and multiply so fast as to cover the

whole surfaces of plants, and, by corroding their vessels, prevent the motions of the sap. He thinks it very probable, that the excrements of these insects may enter the vessels of plants; and, by mixing with their juices, may spread the infection all over them: for it is observable, that whenever a tree has been greatly infected by this mildew, it seldom recovers in two or three years, and many times never is entirely clear from it after. But he by no means allows these insects to be the first cause of this distemper, as some have mistakenly imagined.

It is observable, that mildews and blights frequently attack only one sort of corn, or fruit, and leave the other species unhurt.

Count Ginanni distinguishes two principal kinds of mildew, one of which spots the blades and stems of corn, and dries upon them, without ever producing any powder, but penetrates through their outward covering, and entirely dries them up. This is generally of a pale colour, either reddish, yellowish, purplish, or blackish; and sometimes a variegated mixture of many colours. The other speedily covers the plant with a moist and thickish substance, which afterwards becomes dry, and turns into a powder of one or other of the above-mentioned colours, but most commonly reddish or yellowish. This, says he, always fades, corrodes, and separates the outer skin from the plant. The former extends to every species of corn; but the latter is almost peculiar to wheat in the blade; though it is sometimes seen upon oats and barley. Some may perhaps reckon, as a third species of mildew, a yellowish substance, or powder, sometimes seen under the membrane of the blades of corn, where it raises blisters, makes many little holes and cracks, and corrodes the fibres; and perhaps they may not be wrong in accounting it such.

He is confident that this distemper is the *rubigo* of the Latins.

"For the vegetation of seeds," continues count Ginanni, "after they have been properly deposited in the earth, for their fecundity, their sprouting, and the increase and well-doing of the plants produced by them, it is necessary that the action of the fluid which pervades them be duly regulated: for that fluid is operated on in them by the same causes which affect the liquor in a thermometer and barometer, or influence the hygrometer; so that whenever its due course is obstructed or weakened, or its quantity too much increased or diminished, or its quality injured in any manner whatever, a distemper will ensue. This fluid is subject to two laws of motion; the one, simply as a fluid, which consists in an intestine agitation of its minutest particles; and the other, as a fluid whose progress is through the various ducts of the plant. By the first of these motions it assimilates to itself all the homogeneous particles, and expels the heterogeneous; and by the second it penetrates into the various parts where those functions are to be performed. When both these motions proceed naturally, equally, and justly, the secretions are duly made, and every part of the plant continues sound and healthy: but when that harmony is interrupted, the fluid degenerates from its natural state, and the secretion becomes vitiated and depraved.

"Now, if the several distempers to which plants are subject are owing to the various ways in which the regular action of this fluid may be hurt; and no one distemper can, in my opinion, happen to corn, which will not fall under one or other of these circumstances, we ought to search after and endeavour to discover them, in order to be thereby enabled to prevent, or to cure them, that mankind may be the less exposed to the injuries resulting therefrom. But as the knowledge of these particular things depends on an adequate conception of those which are universal; and as the universal causes of distempers are external or internal, and the distempers themselves seem particularly to depend on the constitution of the air, or an alteration of food, or on both; so when we have discovered the genus of the cause, it will not be very difficult afterwards to find out the species, and the efficient cause. So many and various have been my researches, observations, and experiments, and such the lights which they have afforded me, that, if the love of truth did not oblige me to be dissident of myself, and if I was not thoroughly persuaded, with that great philosopher and mathematician Galileo, that we cannot in general understand how Nature acts, because she makes use of means frequently beyond the reach of our comprehension, I should, perhaps, flatter myself with thoughts of having discovered the origin of

of some of the distempers to which corn is subject whilst in the blade."

He then gives his opinion of mildews, which is, that they come on very early in the morning, and cover the corn almost instantaneously, after a cold night, which has been preceded by a hot day; and that the sap or moisture which then issues out of the plant, is gradually exhaled, and forms the rusty powder which characterises this distemper.

After trying in vain all the boasted remedies of the ancients (highly commended by several modern writers) such as burning of straw and weeds in a serene night, when not a breath of air is stirring, or the wind, if any does blow, comes only from the west, sticking up branches of laurel &c. sprinkling the corn with tobacco, and with pepper; and strewing among it, as Dr. Hales advises, woollen rags steeped in a strong solution of salt of tartar, or sea-salt, or in good white wine vinegar, and afterwards well dried; even from which last he cannot say that he has found much benefit; the method long ago directed in this case by Mr. Worlidge, of making two men go at a proper distance from each other in the furrows, holding a cord stretched straight between them, and carried so as to shake off the dew from the tops of the corn, before the heat of the sun has thickened it, succeeded best of all; to which he adds, as an excellent preservative, keeping the ground perfectly free from weeds, and stirring the earth frequently between the plants. I ought not to omit here Mr. Worlidge's farther observation, that "the sowing of wheat early has been esteemed, and doubtless is, the best remedy against mildews; for by this means the corn will be well filled in the ear before those dews fall, and the increase will consequently be the greater. For curiosity sake, wheat was sowed in all the months of the year: that sown in July produced such an increase as is almost incredible. In France, they generally sow before Michaelmas.

"Bearded wheat is not so subject to mildews as the other, its awns keeping the dew from the ear."

MILKING. Mr. Young, in his *Annals of Agriculture*, gives the following account of milking:

"Having taken several large tea-cups, exactly of the same size, one of these tea-cups was filled at the beginning of the cow-milking, and the others at regular intervals, till the last, which was filled with the dregs of the stroakings: these were each weighed; the weight of each cup being settled, so as to ascertain that the quantity of milk in each was precisely the same, and from a great number of experiments, frequently repeated, with many different cows, the result was, in all cases, thus:

"The quantity of cream obtained from the first drawn cup, was, in every case, much smaller than from that which was last drawn; and those between, afforded less or more, as they were nearer the beginning or the end. It is unnecessary here to specify these intermediate proportions; but it is proper the reader should be informed, that the quantity of cream obtained from the last drawn cup, from some cows, exceeded that from the first, in the proportion of sixteen to one; in other cows, however, and in particular circumstances, the disproportion was not quite so great; but in no case did I find it fall short of the rate of eight to one. Probably, upon an average of a great many cows, it might be found to run at ten or twelve to one.

"The difference in the quality of the cream, however, obtained from these two cups, was much greater than the difference in the quantity. In the first cup the cream was a thin tough film, thinner, and perhaps whiter, than the paper on which I write; in the last, the cream was of a thick butyrous consistence, and of a glowing richness of colour, that no other kind of cream is ever found to possess. See *DAIRY and Cows*.

MILKNESS, a dairy. See *DAIRY*.

MILLET, the name of a plant, which grows naturally in India, from whence it was first imported into Europe, is greatly cultivated in Italy, Spain, and the southern parts of France, for the food of men as well as for that of poultry: and we also raise it in several places in England; though we have our annual supply of this grain from the East-Indies, which makes some people erroneously call it East-India wheat.

It delights in a light sandy soil, prepared in the same manner as for maize; and in such land it branches out into many stalks, sometimes thirty or forty, not unlike reeds either in their shape or leaves, of which there is one

at each joint. The top of each stalk is terminated by a large, loose panicle, which hangs on one side, with a chaffy flower, which is succeeded by a small round seed, about the bigness of turnip or cabbage-seed, of a yellowish white colour in one sort, and of a dark red, inclining to black, in another. The small millet, and the large, a distinction which some writers make, are only varieties of the same sort. It is likewise said to thrive extremely well in strong land: but will not do in stony ground, or where the bottom is either chalk or clay.

Mr. Miller directs sowing this grain in the beginning of April, which may be very right in this country; that it may be ripe in August: but in warmer climates, the general rule is to sow it either between the middle and the end of May, or at Midsummer. The former is reaped at the end of September, and the latter about the end of October.

The seed is sowed in furrows, very thin, and covered with the plough or rake. The largest sort should be sowed thinnest, because it branches most. When the plants are about a month old, the ground should be stirred round them with a hand-hoe, as well to lay fresh earth to their roots, for they require a great deal of nourishment, as to clear them from weeds, of which they will afterwards prevent any great increase, by over-topping them. At the same time, the millet should be thinned wherever it grows too close, so as to leave, in general, about six inches between each plant. The husbandman has nothing more to do to this grain till harvest, excepting that, when it begins to ripen, he must take great care to protect it from birds, which would otherwise soon devour it. If preserved from them, the returns are very great; for it is not easily hurt by drought or rain, nor is it subject to blight. Frequent showers of rain are of great service to it whilst growing.

When the millet is ripe, its panicles are cut off near the uppermost joint of the stalk, with a knife, and put into baskets or sacks, in which they are carried home, where they are then laid up in heaps, covered over with cloths, and after remaining in that situation five or six days, are spread upon the barn floor, threshed out with a flail, and cleansed like other grain. Great care must be taken to dry it well in the sun, before it is laid up in the granary: for it would soon spoil if the least moisture were left in it; this being of all grains the most difficult to keep, unless it be thoroughly dry; and, on the other hand, none keeps longer or better, after it has been well dried. It is not liable to the weevil: and though it should be turned from time to time in the granary, yet if that happens now and then to be neglected, it still keeps perfectly well.

It has been a constant observation, that the late sown millet, I mean so late as Midsummer, had always had the greatest number of abortive grains; that its panicles are smaller than those of the same grain sowed earlier; and that the crop was less plentiful.

The small white millet, which is by far the most delicate, and of which excellent puddings, &c. are made, is the sort chiefly cultivated in this country. The red, which is much larger and coarser, is not used here, except, perhaps, for pigeons, poultry, and swine, for which last it should be ground to meal: but the peasants about Bourdeaux, where a great deal of it is raised in the poor, light lands near that city, make of it a reddish, heavy, ill-tasted bread, difficult to digest. The culture of this sort, which is Mr. Miller's *forgrum*, is, in all respects, the same as that of the white; excepting that, as it grows much larger, the plants require more room.

Millet, either green, or after its grain is threshed out, is very good fodder for cattle, for which use it may be sowed thicker than for a crop of grain. Its many roots, large size, and quick growth, are said to render it a great impoverisher of the earth; for which reason some people pull up the roots, and plough the ground immediately, as soon as the crop is reaped: but others, more judicious, plough in the stubble and roots, which rot, and greatly enrich the soil: and indeed all other succulent plants, instead of being such robbers as is commonly supposed, return to the earth, by the inspiration of their leaves, and perspiration of their roots, even while they grow, perhaps as much as they borrow from it: for how should it be possible for them to pierce into the very driest and hardest ground, as we frequently see they do, unless they perspire moisture through their roots? As this plant requires a great

great deal of nourishment, it would probably thrive best in the horse-hoeing husbandry.

The following account of the culture and amazing produce of the African millet, was sent by the ingenious Mr. Burton, to the editors of the *Museum Rusticum*.

"I cannot help mentioning to you, for the sake of your practical readers, the African millet, *sorgum, millium nigrum*, the culture of which is strongly recommended by M. Tschiffeli, who has written a paper on the subject, published in the *Transactions of the Berne Society*. There is something so very extraordinary in this paper, that I am sure you will think a short abstract of it worthy to be inserted in your work.

"Mons. Tschiffeli observes, that this millet is a plant which merits the husbandman's utmost attention, and that for the following reasons: 1. It thrives in all sorts of soils. 2. It neither requires much dung, nor a great deal of tillage. 3. It is not subject to the depredations of birds, which are very fond of panic and common millet. 4. It yields very large returns. 5. Lastly, it does not exhaust the land in proportion to the largeness of the crops.

"He farther says, that the seed of this sort of millet comes originally from Africa, where it supplies the inhabitants with food; but that they are mistaken who thence conclude it will thrive only in hot countries: for Providence has endowed it with such excellent qualities, that it may, with success, be cultivated in countries much colder than Switzerland.

The first seed of it M. Tschiffeli received was from Mr. Engel, magistrate of Eschalens, who procured it from Pomerania, it being sent to him by the celebrated doctor Schreber, in the spring of the year 1760. M. Tschiffeli had from him about a spoonful.

"In the month of May of the same year, he sowed it on a gravelly soil, hard and stony, very much exposed to the north wind, and which the year before had borne some very indifferent bere. In the month of February preceding, some human ordure had been laid on this land: and in May the clods were all broken before the seed was spread: having so small a quantity of seed, he took care to spread it very thin; and to this does he ascribe the stalks running to the height of eight feet or more. The ears were above ten inches long; and if a shower of hail had not fallen on it, the spoonful would probably have produced him at least a peck. This accident occasioned the loss of half his seed: he had, however, enough left to divide with his friends in Switzerland, as well as elsewhere.

"In the month of May, 1761, he sowed about a quart of seed, or near a pound, on some land, from which he had first pared off the turf, and afterwards burnt it. The space on which the seed was sown might be about twenty paces long, and ten broad.

"Some time before harvest, M. Tschiffeli perceived he should have allotted three times as much ground for that quantity of seed. The stalks, which were very close, were interwoven one with the other, like the hairs of a brush. They were scarcely five feet in height, and the ears also were much shorter than the preceding year: this, however, did not prevent his reaping about seven pecks, or above fifty for one. In the year 1762, he sowed about four pounds of seed, or about half a peck, on some pretty good land, being in quantity about thirty square rods or perches. The year before, the same land bore potatoes; and as he had laid on no fresh manure for the millet, and had neglected to plough it before the winter (for it was only turned over with a spade before sowing) he imagined he had not sown the seed too thick; but in this he was greatly mistaken; the millet came up almost as thick as the year before, and as he had not the courage to thin it, which would have been right, the stalks and ears were shorter than the first year.

"Notwithstanding this, he was enabled to reap twenty bushels, being six hundred and forty pounds; of course, a return of a hundred and sixty for one.

"There can then be no reason to doubt, but that land of a moderate quality, sown thin, and properly prepared, will produce, one year with another, one hundred bushels of millet per acre; for our husbandman got as much in proportion, though his land was but slightly tilled, and he manifestly sowed his seed too thick. This is certainly a most wonderful increase, in what light soever we behold it.

"What grain is there which in the open field will yield a return of one hundred and fifty for one, and which, at the same time, will sell so well? for in price it is on a foot-

ing with wheat. It is true, it yields a heavy, crumbly, and indifferent bread; but if it is made into pottage, it is excellent, very nourishing, and of exquisite flavour. Not only M. Tschiffeli's servants and workmen were very fond of millet thus prepared, but he himself prefers it to the best rice, which will not grow in Switzerland, and comes at a much higher price.

"The millers in Switzerland, whose reputation is not of the best, return a good third of a bushel of millet-meal for every bushel sent to them, after deducting toll, bran, waste, &c. Now this ingenious writer knows by experience, that such a quantity, when made into pottage with milk, will serve at least fifty men for a meal. Surely they cannot be fed at a cheaper rate. In times of scarcity millet must be of great use, as with potatoes the poor might live comfortably.

"An acre of land requires, at most, but ten pounds of seed; and M. Tschiffeli says he can, from his own experience, venture to assert, that millet does not impoverish land in proportion to its produce. The land he sowed in 1760 and 1761, yielded the following year, fine plants of Dutch clover, and rye-grass in as great plenty, with respect to the crops, as the neighbouring land."

MILL-HOLMS, watery places about mill-dams.

MISLEN, the same with maslin, or maslin-corn. See MASLIN-CORN.

MIST, a meteor consisting of gross vapours floating near the surface of the earth.

The bluish mist, which we sometimes see on our fields and pastures in a morning, though often innocent, yet has been in some places found to be the actual cause of murrain, and other fatal diseases among the horned cattle.

Dr. Winklar gives, in the *Philosophical Transactions*, an account of a murrain affecting the cattle in Italy and other places, which was evidently seen to spread itself over the countries in the form of a blue mist. Wherever this was perceived, the cattle were sure to come home sick; they appeared dull and heavy, and refused their food; and many of them would die in four and twenty hours. Upon dissection there were found large and corrupted spleens, splaculous and corroded tongues; and in some places those people who were not careful of themselves, in their management of the cattle, were infected and died as fast themselves. The principal cause of this disease seemed to be the exhalation of some unwholesome steams from the earth; and it was observable that there had been three earthquakes in Italy the year before it happened. The method of cure which succeeded best, was this: as soon as any beast appeared to be sick, they examined the tongue, and, if aphæ, or little blisters, were found on it, they scraped it with a silver instrument made with sharp teeth at the sides, till it bled in all those parts where the aphæ were; the blood was then wiped away with a cloth, and the whole tongue washed several times with vinegar and salt. After this the following medicine was given internally:

Take of foot, brimstone, gunpowder, and salt, of each equal parts; mix these in as much water as will make them thin enough to be swallowed, and let a spoonful be given for a dose three or four times a day.

The cattle which were in health had this medicine given them, as well as the sick; and the consequence was, that very few died in Switzerland, while almost all died in other places.

It was very remarkable that the contagion, on this occasion, seemed to travel slowly and regularly on; it came at the rate of about two German miles in twenty-four hours: this it kept regularly to, during the whole time of its raging, and never appeared in very distant places at the same time.

The whole surface of the earth emitting these effluvia, no cattle escaped them in the course of their way; but those which were kept within doors at rack and manger, fell ill at the same time, and in the same manner with those in open fields. Dr. Stare was of opinion, that it was owing to certain insects which could not fly faster than at the rate of two German miles a day; and that they travelled regularly, and spread the mischief where they passed; but there wanted some judicious persons, versed in these observations, to have examined both the state of the air, and the beasts, on this occasion. *Philos. Transactions*, Numb. 145.

MIXEN, a dung-hill.

MIZZY,

MIZZY, a bog, a quagmire.

MOAR-LOVRE, a term used to express a peculiar distemperature of corn, generally comprehended under the common term of a blight. In this case the earth sinks away from the roots of the corn, and leaves the plant standing in great part above ground with naked roots; these being too weak to support the stalks, the plants fall, and the ears become light. This is a distemperature peculiar to corn growing on light and loose lands. *Tull's Horse-hoeing Husbandry*.

The remedy is this: turn a shallow furrow against the rows, when they are strong enough to bear it, and the mould is fine and dry; the motion of the stalks with the wind will draw in this loose powder, and it will spread itself equally among all the rows, settle about the roots, and cover them.

MOLE, a small animal too well known to the husbandman, from the mischief it does in the fields, by loosening of the earth, and destroying the roots of corn, grass, and other vegetables.

The common method of destroying them is by traps, made in the following manner:

Take a small board, about three inches and a half broad, and five inches long: on one side thereof raise two small round hoops or arches, one at each end, like the two hoops or bails of a carrier's waggon, capacious enough for a mole to creep through easily: in the middle of the board make a hole about the bigness of a goose-quill, and have in readiness to put into it a stick about two inches and a half long, fitted at one end to the hole, and a little forked at the other. Cut also a hazel or other stick, about a yard, or a yard and a half long, which will rise with pretty strong elasticity, when it is stuck into the ground; and to the end of this stick fasten a very strong noose of horse-hair, made so as to slip easily. Have likewise in readiness four small hooked sticks: then go to the furrow or passage of the mole, and after you have opened it, fit in the little board with the bended hoops downward, so that when the moles passes that way, it may go directly through the two semicircular hoops. But before you fix the board in this manner, put the hair string through the hole in the middle of it; place the noose in a circular form, so as to make it answer to the two hoops; put the small stick before-mentioned gently into the hole in the middle of the board, so as just to stop the knot of the hair spring, without entering so far as absolutely to tighten it. Then fasten the board down with four hooked sticks, and cover it with earth. When the mole, passing in its furrow, comes into this trap, it will displace the small stick that hangs perpendicularly downward, the knot will then be drawn through the hole, and the noose instantly straightened by the rising of the end of the hazel stick to which it is fastened, which will catch the mole round the neck.

Others, watching their motions in the morning and evening, which are their usual times of stirring, dig them out in a moment with a spaddle: and about March, which is their time of breeding, numbers of their young ones may be destroyed by turning up their nests, which are generally in the greatest hills; and the old ones who come to seek their young will presently be taken.

Some commend the pot-trap, which is a deep earthen vessel set in the ground with the brim even with the bottom of the mole tracks. The season for using this is when the moles couple, which is about the beginning of March, or perhaps somewhat earlier.

M. Worlidge says, they may be driven from the gardens, meadows, and other places where one would not choose to dig, by fuming their holes with brimstone, garlic, or other unfavourable things: and that the putting a dead mole into a common haunt, will make them absolutely forsake it: to which Mr. Mortimer adds, but only upon report, that white hellebore and the roots of palmar-christi, dried, powdered, and sifted through a fine sieve, then mixed with barley-meal and eggs, and worked into a paste with wine and milk, will kill them, if laid in little pellets under their hills.

The writers of the *Memoirs of the Society of Agriculture at Angers*, recommend hazel-nuts boiled in an infusion of hellebore, as a sure method of destroying moles. Two or three of these nuts are to be laid under each mole hill, and the creatures, by being fond of that fruit, will be poisoned by eating them.

The way to remove mole-hills and ant-hills, which are not only disagreeable to the sight, but detrimental to the

pasture, and a great hindrance to the mowing of the grass, especially where they are numerous, is particularly in regard to the latter, either to divide the turf which grows over them, into three parts, with a spade, or other instrument, then to pare it off each way, to dig out the middle or core of the hills, to spread this mould over the other ground, to leave the holes open all the winter, that the ants may be killed, or lay the turf down again in the spring, and to roll those spots after the reinflated turfs are settled, and their grass has taken fresh roots; or, which is a more expeditious method, to scoop them out at once, with what Mr. Bradley calls a scoloped mole-hill plough, made in the following manner:

From *a* to *a* (fig. 1. Plate XX.) is an iron plate, about five inches over, and above an inch thick at the back, *b b* is the scoloped spade, or tongue of the plough, and about a foot over at the widest part. This, from the sharp point, grows thicker by degrees, till it comes to the back, which should be a full inch thick. The iron must be well hardened, and very sharp at the edges. *c c* is the paring plate, which should be very sharp on the fore edge, and, with the scoloped spade, should be four feet long from *a* to *a*. *d d* are iron sockets, in which are fixed the plough handles, or stils, *e e*. At *a a* are foot-links to set the harness on, for one horse, or two horses lengthwise, to draw by.

When this plough is used, the point of the scoloped spade must be set to the bottom of the hill, by raising the plough stils, so that it may go into the ground; and when the hill is near cut through, the point should be raised up again, by weighing a little on the stils.

The hollow left by this plough will receive the rain as it falls, and this will drown the remaining ants.

After the mole and ant-hills, and other inequalities have been thus taken off, the best way is to carry them to a corner of the field, there to break them well to pieces, and mix them with a considerable portion of lime, or other manure suited to the soil, which will effectually destroy every remains of the ants, and convert the whole to good manure, which may then be profitably spread all over the surface of the ground. The spots on which the mole, or ant-hills stood, should be loosened with a spade, then mixed with lime or other manure, and afterwards be laid down with clean grass seeds.

This method is the most adviseable of any, because a fine grass will be raised in those places, instead of the coarse benty growth which occupied them before.

MOLES in the Fields, may be destroyed by taking a head or two of garlick, onion, or leek, and put into their holes, and they will run out as if frightened, and you may with a spear or dog take them.

Or, pounded hellebore, white or black, with wheat flour, the white of an egg, milk and sweet wine or metheglin, make it into a paste, and put pellets as big as a small nut into their holes, they eat it with pleasure, and it will kill them.

Blith, in his *Book of Husbandry*, says, if you have the conveniency to let water over your ground, it will destroy the moles as far as it goes.

The juice of wild cucumber, or the dregs of oil, poured into their holes, effectually kills them. Or having made a strong lye of water and copperas, early in the morning pierce holes in all the mole-hills with a large stick, and pour this water into the holes in the evening, and it will destroy them.

Make a paste of the powder of the bark of dogs-cole, mixed with rye, barley, or wheat-flour, and wine and milk; put small bits of this into their holes, and they will feed on it till they die. Marking-stone, mixed with wild cucumber-juice, will kill them, if poured into their holes. Some persons place traps at the mouths of their holes; and sometimes they are destroyed by cats and tame weasels.

By the sides of banks, in cart-ruts, in March and April, when the ground is soft, and they burrow but a small depth into the earth, having observed new-made hills, tread them down softly; and then at her customary hours of working, (which in spring-time is generally about six, eight, and eleven in the morning, and three, four, and seven, in the afternoon) she will raise up the earth in the trenches: you must then listen and watch carefully, and you will see or hear her move the earth in the trench. Then fix the broad end of your staff across the holes behind her, and place your foot before her, thus stopping up the way, both behind and before; and then take her up with your spattle.

About sun-rising moles generally go abroad : in moist weather they go out both morning and afternoon ; but in dry, hot weather, seldom but in the morning : they work under hedges, bushes, and trees, in frosty weather. In winter, and in wet seasons, they lie chiefly under the roots of trees, in hedges or banks, and go out every morning to feed, returning in about two hours : when the weather is dry, they go two or three hundred yards. Having remarked where they have been, make trenches, and chop down, with the broad end of your staff, the earth which the mole hath raised, or passed through, and tread it down with your foot lightly in trenches : make trenches in the most convenient places : if this be near their holes, it is best to take them going out, or returning. The most proper places for making trenches are by the sides of hedges, or near the banks, and roots of trees.

It has been said, that if, in gendering time, a bitch mole is drawn or led along the ground with a string, the bucks will follow, so that they may be caught, by a pot placed in the ground for that purpose.

In places you would not dig nor break much, the fuming their holes with brimstone, garlick, or other unfavourable things, drives them away ; and if you put a dead mole into a common haunt, it will make them absolutely forsake it.

Or, take a mole-spear or staff, and where you see them cast, go lightly ; but not on the side betwixt them and the wind, lest they perceive you ; and at the first or second putting up of the earth, strike them with your mole-staff downright, and mark which way the earth falls most : if she casts towards the left hand, strike somewhat on the right hand, and so on the contrary to the casting up of the plain ground, strike down, and there let it remain : then take out the tongue in the staff, and with the spattle or flat edge dig round about your grain to the end thereof, to see if you have killed her ; and if you have missed her, leave open the hole, and step aside a little, and perhaps she will come to stop the hole again, for they love but very little air, and then strike again ; but if you miss her, pour into her hole two gallons of water, and that will make her come out for fear of drowning ; mind them going out of a morning to feed, or come home when fed, and you may take a great many.

Mr. Marshall, in his *Rural Economy of Yorkshire*, says, that "a man whose examinations are seldom superficial, is clearly of opinion, that moles are useful to the farmer. And under this idea he has not had a mole killed upon his farm during the last twenty years. He believes them to be useful in draining the soil ; in communicating air to the roots of plants ; in raising fresh mould upon grass-land ; and in killing worms ; which, he conceives, feed upon the roots of grass and corn.

"That moles are useful to cold, strong-textured land, and to grass-land in general, is probably a fact ; and this may account for the opinion under notice, which was formed on soil of that description ; or on grass-land of a more loamy nature.

"But admitting the moles are useful upon cold, stony, grass-land, it does not follow that they likewise are useful on light, thin-soiled, arable land. Their mischiefs are, here, too obvious to be overlooked."

MOLTEN-GREASE, a fat or oily discharge with the dung, and arises from a colliquation, or melting down of the fat of the horse's body, by violent exercise in very hot weather.

It is always attended with a fever, heat, restlessness, starting, and tremblings, great inward sickness, shortness of breath, and sometimes with the symptoms of a pleurisy. His dung will be extremely greasy, and he will fall into a scouring ; his blood will have a thick skin of fat over it when cold, of a white or yellow hue, but chiefly the latter ; the congealed part, or sediment, is commonly a mixture of size and grease, which makes it so extremely slippery, that it will not adhere to the fingers, and the small portion of serum feels also slippery and clammy. The horse soon loses his flesh and fat, which probably is dissolved and absorbed into the blood ; and those that survive this shock commonly grow hide-bound for a time, their legs swelling both before and behind, and continue in this state till the blood and juices are rectified ; and if this is not done effectually, the sore, or some obstinate furfeit, generally follows, very difficult to remove.

In the first place, bleed plentifully, and repeat it two or

three days successively in smaller quantities ; two or three rowels should also be immediately put in, and cooling emollient glysters daily thrown up, to abate the fever, and drain off the greasy matter from the intestines. By the mouth give plenty of warm water, or gruel, with cream of tartar, or nitre, to dilute and attenuate the blood ; which in this case is greatly disposed to run into grumes, and endanger a total stagnation.

When the fever is quite gone off, and the horse has recovered his appetite, gentle aloetic purges should be given once a week, for a month or six weeks, in order to bring down the swelled legs ; but if the purgative ingredient does not exceed half an ounce, or six drams of fine aloes, it only opens the belly gently ; and, with the other medicines joined with it, passes into the blood, acts as an alterative, and operates both by urine and perspiration : as will appear by the horse's staling plentifully ; and the kindly feel of his skin. To this end give the following, which, repeated for some time, will entirely remove this disorder :

Take of succotrine aloes six drams ; of gum-guaiacum powdered, half an ounce ; of diaphoretic antimony, and powder of myrrh, of each two drams : make into a ball with syrup of buckthorn.

Or it may be prepared with an ounce of aloes, six drams of diapente, and a spoonful of oil of amber.

These will seldom take a horse from his business above two or three days in a week ; neither will he lose his flesh or appetite with them, which cannot be obtained by any other method of purging and gives this greatly the preference in many cases.

Two ounces of nitre mixed up into a ball with honey, and a dram of camphire, will also be found an excellent medicine for this purpose, as it will powerfully attenuate the blood, and promote the due secretions ; to which end it should be given every day for a fortnight, or three weeks. *Bartlett's Farriery*, p. 168.

MOLTER, the toll of a mill.

MOON-EYES ; a horse is said to have moon-eyes, when the weakness of his eyes increases or decreases, according to the course of the moon ; so that in the wane of the moon his eyes are muddy and troubled, and at new moon they clear up ; but still he is in danger of losing his eye-sight quite.

MOOR, a very fine black mould, sometimes found under a pretty thick sward of grass, but more frequently under moss, or straggling plants of heath.

It differs from peat, in that it does not stick together, nor has the fibrous roots, or bituminous viscous quality of this last. Peat, when dry, becomes hard and firm : this falls into powder. It cannot be better described, than by comparing it to that substance which is found in hollow, rotten willows, and other trees of that kind ; which gives room to think that it arises from rotten plants. It is of a spongy nature, and ready to imbibe moisture, which adds considerably to its weight. There is generally underneath it, as under most earths of this kind, a bed of clay, or some substance impervious to water : so that the particles of bodies decayed on their surface, not being admitted into the soil, remain upon that surface, dry there, and increase its thickness, according to the continuance of the cause.

If this kind of soil is collected in a place where running water, in rainy seasons, brings with it clay, or other fat soils, from the neighbouring grounds, it then acquires a greater degree of cohesion, hardens when dry, and resembles the cleansing of ponds more than the former.

The most considerable soil of this kind is the sort called peat. This is usually full of roots of weeds, and even of trunks and branches of trees and other plants. It always contains a bituminous oil, which renders it very inflammable when dry ; at which time it also becomes very hard, though it is quite soft when in the mine, if we may be allowed to give that name to the bed in which it lies ; for there it is easily cut in the form of bricks, as we see it when used for fuel.

"The whole mass and body of this soil, says Mr. Maxwell, is a dunghill, made up of rotten timber, grass, weeds, and often mud washed from the higher grounds about it, by the land-floods ; than which there are few richer composts : only by age, and its cold situation in water,

water, pent in about it by the neighbouring rising grounds, its salts are weakened, and its spirits become languid. The same will happen to the richest dunghill that can be made of any composition whatever, if too long kept. It will even become such as not to be distinguished by the eye, from ordinary moss; nor will it be more useful, as dung, except either in proportion to the shorter time it has been kept, or the better situation of the place where it has stood. I believe the qualities of mossy grounds differ very little from one another in any other respect, than with regard to the better or worse quality of the mud which makes a part of their composition. They are more or less spongy, in proportion as this rich mud fills up the cavities of the component vegetables, which are preserved from putrefaction by the acid in the water. The less spongy, and the more rotten the moss is, the fitter it is for the vegetation of any thing planted in, or sown on it."

The first thing to be done, in order to the improvement of moor, is to divide them into proper inclosures; not only to secure their future produce, but also to be a means of procuring rich earth to cover the otherwise insipid useless mould on the surface, and give root to the plants which may afterwards be cultivated in them. Then, as the natural produce of this earth is of no value, its surface should be pared off, in order to be burnt: but as this subject, of burning earth, has been before fully treated of, we shall only observe here, that the husbandman should be very careful not to make the clods too dry, or light his fires in too dry a season, lest they should extend farther and deeper than was intended.

If the depth of the moorish earth be not very considerable, the surrounding ditches, which make the inclosure, will afford the rich strong soil, which should be spread about three or four inches thick all over the surface. When the clods are burnt, their ashes should be mixed with this new soil. If no proper earth can be got from the ditches, sand or gravel may be used with success, as was practised by the ancients. Gravel is singularly beneficial to such lands; as has been shewn under the article Bog.

The Berne Society, who recommended this method of improvement as founded on repeated experience, very properly observe, that the good effects of the sand and gravel will be considerably increased by a moderate mixture of dung, and that, especially if the ground be intended for ploughing, this covering should be at least a hand's breadth in thickness. Dung alone would undoubtedly be extremely efficacious on all such soils, in which it is remarked to be of longer service than in any other; but the farmer can seldom spare a sufficient quantity of it to go far enough unmixed, nor indeed for mixing. In this case, other ingredients must be resorted to; though the sand, or gravel, will generally do great things without any mixture. Well preserved ashes will be of excellent service, and so will the rubbish of old buildings, or any other similar substance, when mixed with the sand or gravel, even of the coarser kind, and incorporated with this naturally rich earth, which, were its real value known, and the proper method of treating it rightly understood, might claim a preference before any other soil. Loam is still better than either sand or gravel. This should be brought on before the fires are lighted to burn the surface of the moss, and should remain in heaps till it can be equally mixed with the ashes. Lime, where it can be had, will also contribute to the meliorating of mossy grounds. The moorish earth, thus covered, is fitted for various kinds of crops.

Mr. King, who observed that the places and bogs in Ireland, where a little earth had chanced to fall as the peasants were carrying it to mend the ways across them, became a green soil, covered with a fine Scotch grass, does not doubt but that the same expence as sands or gravels land, would bring a dried bog even to be arable; and as to the common opinion that gravelling is bad for grass, the contrary, he says, is apparent; especially in bogs. Another method of reducing barren, boggy land, in Ireland, is by laying upon it a little dung or straw, and covering this with shells.

A strong proof of the propriety of covering moss with earth, results from a fact which happened to Mr. Graeme, near Stirling. Two years after this gentleman had earth his moss, which he had not yet sowed, it was as full of natural white clover, and other grass, as any field generally is in twice that time.

In the province of Groningen, they pare off the upper

surface of the soil, which is a light, loose earth, and lay it by till they have dug out the peat underneath, when they mix it with the sand which lies under the peat, and sow it with rye and hay-seed the first year; after which they let it run to grass, and have amazingly fine crops. In Sweden, a drained bog was remarkably improved by a peasant who burnt upon it a parcel of useless wood and lime-stones; and another converted his drained bog into a fine meadow, by covering it with lime and tanner's-bark.

Mr. Elliot, after draining a very remarkable swamp, sowed it with grass-seed such as red clover, spear-grass, fowl-meadow grass, and herd-grass; none of which came up so well as the red clover, which he found to be the boldest and most hardy. Though this came up well, yet, where the sward was strong, what with the toughness of the ground, and the over-topping growth of the wild natural grass, it made but slow progress till the fall of the year, and then it mended considerably. The other sorts of grass came up but poorly, the land being, as Mr. Elliot judges, too new and tough for them. In September he ploughed up a piece of this ground, where he had not sowed any grass. It ploughed very tough, and the cattle mired in some places; but he kept them as much as possible upon the grass; notwithstanding which there was a necessity of leaving many baulks. About a month after, he ordered these baulks, to be hoed up, and was agreeably surprised to find how easily this was done. He found the meadow rotted and mellowed more in one month in the fall, than it had been the whole summer; but thinks the ploughing would have been performed with much greater ease, if it had been deferred till a month later. In July he sowed a little piece with turneps, which came up, but did not grow well till the ground began to rot in the fall of the year, when they throve perfectly, and were good and sweet, instead of being rank, as he expected.

This gentleman found by experience, that such drained land must have one summer to ferment and rot, so as to become proper soil, before it will be fit for the grain or every sort of grass. "If, says he, I had sowed red clover instead of the other sorts of grass, I had saved five pounds in seed. Clover out-did my expectation, and the other sorts fell short of it. If others save where I lost, and mend wherein I was mistaken, it answers my design in writing.

"By a little experience which we have had of these drained lands, we find they will produce Indian corn, sixty or seventy bushels to an acre, and flax. If life and health be continued, I design to try liquorice-roots, barley, Cape-Breton wheat, cotton, indigo-seed, wood for dyeing, and the water-melon. But what I have principally in view is hemp. New-England doth not, I suppose, expend less than several hundred thousand pounds worth of foreign hemp yearly. If we can rise more than to supply our own occasions, we may send it home. It is not a mere conjecture, that the drained lands will produce hemp. I am informed by my worthy friend Benjamin Franklin, esq. of Philadelphia, that they raise hemp there upon their drained lands.

"Hemp requires such very strong land to produce it, that it would consume all our dung to raise it in any great quantities; so that we should not be able to raise bread-corn: therefore, how inviting soever the trade is, and how great soever the encouragements have been, both from home and by our own government, we have not as yet engaged in that affair. We have now a promising prospect of success in these drained lands: what may be the issue, time and experience must determine. A meadow of drained land, which could be laid under water, and this drawn off at pleasure, would probably be of great value. I have heard that a man in the Jerseys hath such a meadow, which though only half an acre in extent, yields him as much hemp yearly as sells for fifty pounds.—York money: but this seems incredible."

Whatever advantages are reaped from hemp, may also be received from flax, if rightly managed, upon mossy grounds. Some improvers in Scotland have already tried it with success, and, though a new attempt, doubt not its answering well in that kind of soil. The most approved method of cultivating and dressing each of these singularly beneficial plants, are given under the articles HEMP and FLAX.

"It is common in swamps, continues Mr. Elliot, to find the moss two or three feet deep. At first, I was perplexed how to get rid of it, and somewhat doubtful whether the land

land would be worth any thing, if this surface was removed. When the water was drawn off by ditches, the moss grew so dry, that in a hot summer season it would burn quite down to the ground. To burn this, or any other trash you would consume upon land, set fire to it when the weather is clear, the sun hot, and a strong southerly wind blows, which makes fire rage more fiercely, and do much more execution than a northerly or westerly wind. In a northerly wind the air is thin and light, so that the fire is not strongly compressed: the moist heavy south wind prevents the dissipation of the fire, and renders it more compact. Thus we see a smith swob and wet his coals, by which means the heat is greatly increased. Whether this reasoning be just or not, the fact is certain, and that is the chief concern of the farmer.

"Deep swamps are preferable to those which are shallow: for experience shews, that a deep soil bears extreme drought better than any other land, in the hot season. The cold drought in the spring will hurt such land, so that the first crop of grafs will be very great; but the second crop will be extraordinary good.

"The red clover in my drained land above-mentioned, looked in the cold drought at the latter end of the spring, as if it would not come to any thing: but it recovered a good colour, and grew up well, when hot weather came on, though the drought continued. This is such an advantage as will always recommend a soil eight or ten feet deep.

"Our ditching and draining dry only the top of the ground, not more than three feet deep in the hot and dry season; I suppose that the moisture from the mud and water underneath is drawn by the force of the sun, so that the roots of the grafs are furnished with sufficient moisture to bring forward the vast burden they frequently bear. But this is not to be expected till the land be concocted, changed, and altered by the sun and air: for at first, soon after it is drained, it is pinched with the drought more than any other land.

"Those swamps which are thick overgrown with moss, prove as good as any other drained land, when they are so far dried by draining, that the moss will rot, or burn off. I mention this, because it is best that the farmer may work as free from discouragement as possible.

"Our drained land, though in all other respects well adapted for producing Indian corn, is of so loose a texture, that the plants become an easy prey to the crows and other birds, which, if not prevented, will pull up a great part of them, and destroy the crop. To guard against this great discouragement in all such land,

"Take the roots of swamp hellebore (known in different places by the several names of skunk-cabbage, tickle-weed, bear-root) and boil them in so much water as to keep them covered an inch deep: by two hours boiling, the liquor will be of sufficient strength: strain it off; put your corn into it while the liquor is warm, and let it steep twenty hours. It will then be fit for planting.

"This is found to be an effectual security. The Rev. Mr. Todd observes, that after meeting with much trouble and loss, by having his corn repeatedly pulled up, he planted his ground with corn steeped in this liquor; but not having enough of that, he ordered the planting to be finished with unsteeped corn. The event was, that the birds pulled up but two or three hills of the soaked corn, but left not one in ten of those which were planted with unsoaked corn. He planted anew, with steeped corn, the hills where the plants had been thus 'pulled up, except a few of them in the middle of the field, which were planted a second time with unsteeped corn, upon a supposition that the birds would not find them out: but the result was as before: all the unsoaked was pulled up, and the hills planted with the steeped corn were spared.

"Upon the whole," says Mr. Todd, "I think this experiment a full proof that corn so prepared, when planted, is secured from the birds; the knowledge of which may be of great service to the husbandmen, as the preparation is cheap and easy, and our swamps seem to be the best land we have for Indian corn. My little swamp this year yielded after the rate of above ninety bushels to the acre, and was easier and cheaper tilled than the same quantity of upland." See the article Bog.

MORES, or *Mours*, hills.

MORGAN, the same with May-weed. See the article MAY-WEED.

MOSS, a name given to moory or boggy grounds, in many parts of England. These sorts of land consist of a turfy surface, below which is a black, moist, spongy earth, which being dug up with spades, almost in the form of bricks, and dried, is what they call peat, and used as fuel in several parts.

The shortest method of all for the improvement of moss, if the ground be designed only for grafs, and its situation be such as admits of it, is this: first drain the moss, and if there be heath upon it, burn that off, and make the surface even. Then make a dam at the lowest part, and a sluice, and work the water upon it through the winter. The mud which comes with the land-flood will bring a fine sward upon it in two or three years, and be afterwards a yearly manure; so that it will bear annual cutting, and, besides, be good pasture for cattle, after the sward is become strong enough to bear them.

Mr. Græne found that the improvement of moss may be endangered by draining it too much; for his crops were best where the surface of the water in the surrounding ditches was not above three feet lower than the level of the moss. It will, undoubtedly, be a vast advantage to an improved moss, if the farmer is able to flood it at proper times, by means of a sluice in the lowest part of the surrounding ditch, as mentioned before. This will greatly promote the growth of plants; but should be used with the caution of not letting the water remain too long at a time upon the ground, because, though there will be no danger of its re-converting the soil into a bog so long as there are channels to carry it off, it will be apt to chill, and thereby hurt the plants. See the article Bog, and Moor.

Moss on Trees, is a distemper of very bad consequence to their increase, and much damages the fruit of the trees of our orchards.

The present remedy is the scraping it off from the body and large branches, by means of a kind of wooden knife, that will not hurt the bark; or with a piece of rough hair-cloth, which does very well after a soaking rain. But the most effectual cure is, the taking away the cause. This is to be done by draining off all the superfluous moisture from about the roots of the trees, and may be greatly guarded against in the first planting of the trees, by not setting them too deep.

If trees stand too thick in a cold ground, they will always be covered with moss; and the best way to remedy the fault is to thin them. When the young branches of trees are covered with a long and shaggy moss, it will utterly ruin them; and there is no way to prevent it, but to cut off the branches near the trunk, and even to take off the head of the tree, if necessary, for it will sprout again; and if the cause be in the mean time removed by thinning the plantation, or draining the land, the young shoots will continue clear after this.

If the trees are covered with moss, in consequence of the ground's being too dry, as this will happen from either extreme in the soil, then the proper remedy is, the laying mud from the bottom of a pond or river, pretty thick about the root, opening the ground to some distance and depth to let it in; this will not only cool it, and prevent its giving growth to any great quantity of moss, but it will also prevent the other great mischief which fruit-trees are liable to in dry grounds, which is, the falling off of the fruit too early. Mortimer's Husbandry.

False MOTH, an insect which proceeds from a small caterpillar, the body of which is smooth and whitish. It has sixteen legs, does not lodge in the grains of corn, but contrives to fasten several of them together with a web which it spins, and with which it makes itself a dwelling-place, or sheath, in which the caterpillar of the false moth usually abides, is generally in the middle of the little heap of grains which it has collected for its food, but which distinguishes it from the caterpillar of the true moth: it can quit this sheath at any time, to eat the grains around it, one after another. It generally attacks several grains at once, and always without order, eating sometimes of one, and sometimes of another; so that several are gnawn, when not one is wholly consumed. When these insects are very numerous in a granary, all the grains upon the surface of the corn are linked together by a web, so as to form a crust, which is sometimes three inches thick. This caterpillar

pillar turns into chrysalis, or aurelia, in a grain which it has hollowed, or in the sheath of its web, and issues from thence, in the month of June, in the form of a butterfly. When a heap of corn is stirred, in which there are many caterpillars of the species of this false moth, those insects crawl up the walls; but they soon return to the heap, and, by the very next day, cover it all over with a new web.

In its state of moth, it is grey, has six legs, and is frequently seen in vast numbers fluttering about the eaves of the windows of granaries, in the spring and summer, when the weather is very hot. The females lay their eggs upon the heaps of wheat, and these eggs produce the caterpillars, or corn worms, as some call them, which feed on the grain, and envelop it with their silky web, so as to form over the whole surface a crust that is sometimes three or four inches thick. This entirely spoils the corn within that depth, besides communicating a bad smell to all the rest. These worms, or rather caterpillars, for they have sixteen legs, are smooth, whitish, and seldom exceed a quarter, or at most the third part of an inch, when at their full growth. Breaking of their webs avail but little, for they are woven again by the next day: for which reason some have been of opinion, that it is best to let them enjoy undisturbed the surface of the corn of which they have taken possession. But it should be considered, that three inches are a sixth part, and four inches upwards of a fifth, of any quantity of corn spread eighteen inches deep, which is the medium thickness at which it is laid; and that, independent of the bad smell with which the rest is tainted, this is a very considerable object, though it extend no farther. When this crust is broken, most of the grains which compose it are found to be either gnawn in their inside, or full of live worms, or of aureliæ, according to the season; or one sees only the empty sheaths of the caterpillars, if the aureliæ have been transformed into moths.

It is said, that strewing the corn with powdered lime, so as to form a crust over it, will preserve it from the ravages of these insects: but as the surface would still be spoiled, and as that surface may be a considerable part of the small provision of wheat allotted for a family only, M. Duhamel did not try this expedient. Covering it with hay, which he did try, answered no end whatever.

These observations, and the reflections consequent thereon, made him suspect that this insect, as it delights in none but very warm places, would not be able to live in the cold air of his ventilating granaries.

Accordingly, in the winter of the year 1746, he collected all the wormy crusts which these caterpillars had formed in his common granaries, where they were very thick, the moths having been extremely numerous the preceding summer. These crusts were broken and screened; and what grain could be got from them, which undoubtedly was impregnated with the eggs of the moths, was put into one of his granaries of preservation, which contained seventy-five cubic feet, and was ventilated from time to time during all the winter.

Towards the end of May, when the vent-holes at the top of this granary were opened, a prodigious number of moths flew out, which shewed that they did not like their situation.

When the wheat was thought to have been ventilated sufficiently, the holes were shut close, and nothing more was done to it for a month: for as this corn (which had not been stove-dried) was old and dry enough, it was but seldom ventilated.

In June 1747, this granary was emptied: all the moths and worms were dead, and there remained only a thin crust, not above the twelfth part of an inch thick, on the top of the corn, which had so far lost the bad smell it had when put into the granary, that it sold for the current market price.

Not satisfied with this single method, M. Duhamel tried the effect of the stove upon another parcel of wheat known to be full of these worms. A heat from 45 to 50 degrees of Reaumur's thermometer (from 115 to 124 of Fahrenheit's) killed them all. This corn was then laid up in a common granary, where it remained two years without being attacked by any of these moths; and even in the third, but very few of them appeared.

These experiments remove all doubt of the possibility of destroying the corn-moth, or worm, without hurting the grain, which would otherwise be spoiled by it; and as that grain generally is wheat, which the insect prefers to any

other, this discovery is of great importance to the husbandman as, well as to the public.

MOULD, a loose kind of earth, every where obvious on the surface of the ground, called by some, mother earth, and by others loam.

The goodness of a mould for the purposes of agriculture and gardening, &c. may be known, according to Mr. Miller, by the sight, smell, and touch. 1. Those moulds that are of a bright chestnut or hazely colour, are counted the best: of this colour are the best loams, and also the best natural earth; and this will be the better yet, if it cut like butter, and does not stick obstinately, but is short, tolerably light, breaking into small clods, is sweet, will be tempered without crusting or chopping in dry weather, or turning to mortar in wet. Next to that the dark grey and russet moulds are accounted the best: but the light and dark-coloured the worst, such as is usually found on common heathy ground: the clear tawney is by no means to be approved; but that of the yellowish red colour is the worst of all: this is commonly found in wild and waste parts of the country, and for the most part produces nothing but goss, furze, and fern, according as their bottoms are more or less of a light and sandy, or of a spewey gravel, or clayey nature. 2. All lands that are good and wholesome, will, after rain, or breaking up by the spade, emit a good smell. 3. By the touch we may discover whether it consists of substances entirely arenaceous, or clammy; or, as it is expressed by Mr. Evelyn, whether it be tender, fatty, deterfive, or slippery; or more harsh, gritty, porous, or friable.

Mr. Marshall, in his Rural Economy of Norfolk, in a treatise on *mould*, says, "Besides what come under the idea of marles and clays, a variety of other earths are industriously sought after by the Norfolk husbandmen, for the purpose of bottoming their farm-yards and dung-hills; with a view to catch the drainage of the dung. The dung and the mould are afterwards turned up and mixed together; by which means the mould becomes saturated with juices communicated to it by the dung: and it is a common observation, that the mould thus prepared lies longer in the ground, and is a more permanent manure than the dung itself."

"This is not improbable; for crude unmixed dung, buried in lumps, and dissolved in the soil, by heavy rains, is liable, no doubt, to be carried away, in part, below the vegetative stratum; especially of a light soil: therefore, to arrest and fix it, before it be carried upon the land, seems to be, in the management of such a soil at least, highly judicious."

"This piece of good management is talked about in most countries, and practised perhaps by some few individuals: but, in Norfolk, a light land country, it is the universal practice."

"I mean, to bottom dung-heaps with a stratum of mould. It is not equally universal to turn over and mix the dung and mould together; but this is frequently done by good husbandmen. It is not, however, in every case, eligible. A dung heap, formed in the spring, for turneps, would, in a dry season, be injured by such treatment."

"The principal source of this mould, provincially manure, is the shovellings of ditches; which, in this country, are found to contain in themselves a singularly fertilizing property. This rich mould is not composed of the sediment of the washing of the adjoining inclosures; many of the ditches perhaps never having, from the time of making to the time of scouring, admitted a current of water; but consists altogether of dead weeds, leaves of the hedge, and the mouldering of the bank and the sides of the ditch."

MOULDINESS, a term applied to bodies which corrupt in the air, from some hidden principle of humidity therein; and whose corruption shews itself by a certain white down, or lanugo, on their surface, which, viewed through a microscope, appear like a kind of meadow, out of which arises herbs and flowers, some only in the bud, others full blown, and others decayed, each having its root, stalk, and other parts.

MOUND, a bank or fence of earth. *See the article BANK.*

MOW, the pile or collection of corn in the straw, placed in a bay of a barn. *See the article BARN.*

MOW-BURNT, over-heated in the mow for want of being dry.

MOWING, the art of cutting down corn, grass, &c. with a scythe.

M. de L'Isle lately introduced the mowing of wheat. The method is this; the scythe he uses is at least six

inches shorter in the blade than the common scythe, and instead of a cradle has two twigs of osier put semicircular-wise into holes made in the handle of the scythe, near the blade, in such a manner, that one semicircle intersects the other: this method is frequently practised by the men who mow our meadows, as they think a cradle unnecessary and cumbersome, unless the scythe is to carry over a very large and very heavy sward.

In mowing barley, or oats, the corn is always on the right-hand of the workman: but by M. de D'Isle's method of mowing wheat, the corn is at his left-hand: he mows it inward, bearing the corn he cuts on his scythe, till it comes to that which is standing, against which it gently leans. After every mower follows a gatherer, which may be a lad of twelve or fourteen years of age, or a woman. The gatherer keeps within five or six feet of the mower, and being provided either with a hook or stick about two feet long, gathers up the corn, makes it into a gavel, and lays it gently on the ground: this must be done with spirit, as another mower immediately follows: for to every mower there is a particular gatherer.

To do this work properly, the mower should form but one track with his feet, advancing in a posture nearly as if he was going to fence, one foot chafing the other. In this manner the standing corn is mowed; but the workman must take care to have the wind at his left, as it bears the corn towards the scythe, and causes it to be cut nearer the ground. If the wind is behind the mower, it is no great inconvenience: it only occasions the scattering of a few ears; and the cut of corn, which should lean against the standing corn, is sometimes thrown down; which makes the work go on slower, and increase the gleanings. The wind in front is very bad; the corn cannot be cut close, and there is a great loss: but the wind on the right-hand is worst of all; the stubble is left long, and such a quantity of gleanings, that one would imagine no crop had been taken off. When wheat is bent, the workman takes the corn as it presents itself to him, which has the same effect as if the wind was at his left-side. When wheat is laid, it is more troublesome to the gatherer, because the cut corn is apt to be mixed with that which is standing; but a good mower takes the advantage of the wind, and cuts it against the way it is laid. No particular directions can be given for corn that is lodged and entangled, unless it is to take it as it is inclined, as if the wind was in the back of the mower.

This method of mowing of wheat was tried in Northamptonshire, and the following account of it sent to the editors of the *Museum Rusticum*.

"A gentleman, a foreigner, says this writer, came down here to a neighbour of mine, in order to put us into a method of going about this work.

"Many trials were made in the presence of myself, and a great number of others: the scythes did their work well; they cut the corn within two inches of the ground; and though our workmen were of course a little awkward, scarcely any ears were scattered; but the greatest advantage is, that a man with one of these scythes can cut down at least double the quantity of wheat in the day he can with a sickle or hook.

"The chief objections made to the introduction of this method were, that the stubble is left too short, and on that account is not fit for thatching; that the weeds are cut with the corn, and will be apt to mould or heat, and the seeds to mix with the corn in threshing; and that the poor are deprived of their gleanings, as none of the corn is scattered.

"But these objections must soon fall to the ground, when we reflect that, by mowing, the straw is much longer, and certainly straw is much better for thatching than stubble.

"As to the weeds being cut with the corn, it is of no consequence; for they are easily shaken out of the bottoms of the sheaves, after drying a day or two; and the sheaves may be safely left to dry, if they are laid in the following manner:

"Suppose three tobacco pipes to represent three sheaves, the bowls to be the feet of the sheaves, and the small part the ears: lay one of these on the ground; then take another, and lay the bowl of it under the small end of the first; take afterwards a third, and disposing them in form of a triangle, lay the bowl of the third under the small end of the second, and the bowl of the first under the small end

of the third; by disposing them in this form, the ears are always kept from the ground, and will endure a great deal of wet without damage.

"As to the seeds of the weeds being threshed, and mixing with the corn, this may easily be avoided; for the wheat, by this method of mowing it, is so regularly disposed in the sheaf, that the sheaves need only be threshed on the ear, without being unbound.

"The objection that the poor would be deprived of their gleanings, is a mere farce: their time might be much better employed; and by the same parity of reason, the more corn the farmer left for them in the field, the more justice he would do them; and this few would venture to assert, as custom might in time extend it to half the crop: besides, as by this new method, a great deal more corn will be inned, it will of course be cheaper the year round, and easier purchased by the poor.

"The foreign gentleman was of great use to us; he is intelligent and communicative, and we all of us acknowledge ourselves much obliged to him.

"Many in this county purpose making more extensive trials of it next harvest, and there is no doubt but that in the space of a few years it will be brought into constant use.

"A short certificate of the advantages resulting from the practice of this method, was some time ago drawn up; it was presently signed by a number of gentlemen, farmers, gardeners, labourers, &c. and transmitted to Dr. Templeman, secretary to the Society of Arts in London, to be, if necessary, published for the benefit of the kingdom. This new method will doubtless be introduced to the knowledge of the English world with a better grace, coming under the sanction and recommendation of so respectable and useful a Society."

The authors are happy, that, as members of the society, they have an opportunity of conveying to the readers of this Dictionary a perfect idea of the form of the scythes lately tried in Northamptonshire; for this purpose they have annexed a plate engraved from a drawing taken from the three scythes now deposited in the Society's machine-room, for the inspection of the curious. The parts are represented separate, that they might be more distinct: the dimensions and proportions follow. Plate XX. fig. 7. is the handle, or mounting of the largest scythe; the length of it from *a* to *c* is eight feet, from *a* to *b* five feet, from *b* to *c* three feet: at *c* is the part whereon the blade is fixed, *d* shews the two bends which serve instead of a cradle. Fig. 3. is the blade to this scythe; from the heel *a*, to the point *b*, measures three feet, and it is two inches and a half broad; when the scythe is mounted, from the point to the blade *b*, to the end of the long handle *a*, measures an angle of seven feet. Fig. 4. is the blade of another scythe, the length and breadth the same as the last blade. Fig. 5. is the handle to this second scythe; from *a* to *d*, it measures three feet ten inches, from *a* to *b*, two feet, and from *b* to *c*, one foot seven inches; the blade is fixed at *a*, and when the scythe is mounted, the angle from the point of the scythe-blade to the end of the handle, measures three feet nine inches. Fig. 6. is the blade of the smallest scythe; from *a* to *b*, it measures one foot nine inches, and is two inches and an half broad. Fig. 7. is the handle or mounting to this last scythe; at *a* the blade is fixed; from *a* to *b*, is one foot five inches and an half; the angle from *b* to *c*, four inches and an half; from *c* to *d*, five inches; from *d* to *e*, three inches and three quarters. Fig. 8. is the gathering-hook; the length of its handle, from *a* to *b*, is three feet nine inches; the hook from *b* to *c*, is ten inches long. See HARVESTING.

MUCK, dung, or straw that lies rotting. See DUNG.

MUD, the sediment at the bottom of rivers, ponds, ditches, &c. See the article DUNG.

MUGWORTH, a very troublesome weed; for its roots creep far under the surface of the ground, so as soon to overspread a large space, if they are not stopped; and its seeds, being light, and easily carried to a distance by the wind, will produce numbers of new plants the next spring. It has plain cut leaves, ending in many parts, woolly underneath, and single spikes of pale yellow oval flowers, which blow in June.

MULBERRY, the name of a tree, of which there are several species, but two only are generally cultivated, called the black and white mulberry.

The black mulberry grows naturally in Persia, from whence

whence it was first brought to the southern parts of Europe; but is now become common in every part of Europe, where the winters are not very severe: for in the northern parts of Sweden, these trees will not live in the open air; and in several parts of Germany they are planted against walls, and treated in the same way as peach and other tender fruits are here.

These trees are generally of both sexes, having male-flowers or katkins, on the same tree with the fruit; but it often happens, that some of the trees which are raised from seeds, have only male flowers, and produce no fruit; so that those who plant these trees for their fruit, should never make choice of such as have been propagated by seeds, unless they have seen them produce fruit in the nursery. It is also the surest way to mark such trees as are fruitful in the nursery at the time when their fruit is upon them, because those trees which are propagated by layers, are sometimes of the male sort.

The old mulberry trees are not only more fruitful than the young, but their fruit are much larger and better flavoured; so that where there are any of these old trees, it is the best way to propagate from them, and to make choice of those branches which are most fruitful. The usual method of propagating these trees, is by laying down their branches, which, will take root in one year, and are then separated from the old trees; but as the most fruitful branches are often so far from the ground as not to be layed, unless by raising of boxes or baskets of earth upon supports for this purpose; so the better way is to propagate them by cuttings, which if rightly chosen and skilfully managed, will take root very well; and in this method there will be no difficulty in having them from trees at a distance, and from the most fruitful branches. These cuttings should be the shoots of the former year, with one joint of the two-years wood to their bottom; the cuttings should not be shortened, but planted their full length, leaving two or three buds above ground. The best season for planting them is in March, after the danger of hard frost is over; they should be planted in light rich earth, pressing the ground pretty close about them; and if they are covered with glasses, it will forward their putting out roots; but where there is no such conveniency, the ground about them should be covered with moss, to prevent its drying; and where this is carefully done, the cutting will require but little water, and will succeed much better than with having much wet. If the cuttings succeed well, and make good shoots, they may be transplanted the following spring into a nursery, where they should be regularly trained to stems, by fixing down stakes to each, to which the principal shoots should be fastened; and most of the lateral branches should be closely pruned off, leaving only two or three of the weakest to detain the sap, for the augmentation of the stem; for when they are quite divested of the side shoots, the sap is mounted to the top, so that the heads of the trees grow too fast for the stems, and become too weighty for their support. In about four years growth in the nursery, they will be fit to transplant, where they are to remain; for these trees are transplanted with greater safety while young than when they are of a large size.

The white mulberry is commonly cultivated for its leaves to feed silk-worms, in France, Italy, &c. though the Persians always make use of the common black mulberry for that purpose; and it is said that the worms fed with those of the black produce much better silk than those fed with the white; but it is to be observed, that the leaves of the black sort should never be given to the worms, after they have eaten for some time of the white, lest the worms should burst, which is often the case when they are thus treated.

The trees which are designed to feed silk-worms should never be suffered to grow tall, but rather kept in a sort of hedge; and instead of pulling off the leaves singly, they should be sheared off, together with their young branches, which is much sooner done, and not so injurious to the tree.

This white sort may be propagated either from the seeds or layers, as the black mulberry, and is equally hardy; but the most expeditious method of raising these trees in quantity, is from the seeds, which may be procured in plenty from the south of France and Italy. The best way to sow these seeds, in England, is to make a moderate hot bed, which should be arched over with hoops, and covered with mats; upon this bed the seeds should be sown in the middle of March, and covered over with light

earth about a quarter of an inch deep: in very dry weather, the bed must be frequently watered, and in the heat of the day shaded with mats, and also covered in the nights when they are cold. With this management the plants will come up in five or six weeks, and as they are tender when they first appear, so they must be guarded against frosty mornings, which often happen in May. During the summer they must be kept clean from weeds, which is all the culture they require: but there must be care taken of them the first winter, especially to cover them in autumn, when the frosts come, which will kill the tender plants to the ground, if they are not protected; the following March, these plants should be transplanted into the nursery, to get strength, where they may remain two or three years, and then should be removed where they are to continue.

MULE, a mongrel kind of quadruped, usually generated between an ass and a mare, and sometimes between a horse and a she-ass.

The mule is a sort of a monster, of a middle nature between its parents, and therefore incapable of propagating its species; so careful is nature to avoid filling the worlds with monsters. Mules are chiefly used in countries where there are rocky and stony roads, as about the Alps, Pyrenees, &c. Great numbers of them are kept in these places; they are usually black, strong, well limbed, and large, being mostly bred out of the fine Spanish mares.

In Spain there is great encouragement for breeding and training mules to every kind of business: in Portugal they are estimated at a high price, and are not a little valued in the southern parts of France.

I own, says a writer in the *Museum Rusticum*, I have often been astonished (the useful nature of this creature considered) that we do not more encourage the breed in England. This inattention may perhaps proceed from mules being thought naturally more vicious than horses: I doubt the fact; yet be it as it will, they are, to my knowledge, equally capable of being made useful, docile, and gentle.

I assert not this merely from opinion, having had many years experience of what may be done in this way.

During the course of the war, in which his royal highness the duke of Cumberland commanded the army of the allies in Flanders, the empress queen made him a present of above fifty fine mules to carry his baggage: these mules at the end of that war, were brought to England, at which time I had an opportunity of seeing and admiring them. They were, I think, the finest and largest I ever before beheld; and one, nearly white, particularly attracted my attention, being almost sixteen hands high.

This circumstance of seeing his highness's string of mules, it was first induced me to think of breeding them, in which I have since had uncommon success.

I had many encouragements to make the attempt: my fortune was such as could not be hurt by the experiment; my park was extensive, and very proper for the purpose; and I had many servants, who had so little to do, as to have leisure time enough to obey my orders in this matter.

My great difficulty at first setting out was to procure a he ass or two to cover my mares; for I found none were to be got of any size bred in England.

It is true, I met with some Spanish asses; but they were sluggish, and not likely to get mettled colts: besides, I could not buy two of them, of any size and shape, under seven hundred pounds, which I thought too much money to throw away, if I could by any other means get my end easily answered.

Sensible that perseverance does much in all things, I bought a strong-boned, fine-shaped he ass, and two she-asses of a large size, considering they were bred in England, determined to try if I could not by a little care and attention mend the breed, before I attempted to get any mules.

These cost me only four pounds, and my two she-asses soon afterwards dropped a foal each.

I continued to breed from them several years; but it is the manner in which I managed the ass-colts, that the great success I have lately had in breeding mules must be ascribed.

I took care that the she-asses should be well fed, and be kept in order, both before they dropped their foals, and afterwards whilst they suckled.

As soon as the colts were weaned, I had them as carefully

fully attended and fed as if they had been got by Childers or Babram: every winter they stood under cover, defended from the injuries of the weather, and were regularly fed, cleaned, and littered, the door of the stable being always left open two or three hours in the middle of the day, for them to exercise themselves as they thought proper, which they seldom failed to do, if the weather was fine, to some purpose; returning, without compulsion, when the hour of feeding approached.

In this manner I always managed them till they were three years old, when I permitted my stone colts to cover, and my females to breed.

You would indeed be surprised to see how much, by this plain and simple management, my breed of asses is improved: for I have now in my stables several he-asses, which I keep as stallions, that are, I believe, as large, and as well shaped, as any that were ever heretofore bred in these islands.

I shall now proceed to describe to you the manner in which I breed my mules. For this purpose I chuse mares that are of a very large breed, such as are sometimes used to draw the brewers drays in London.

My next care is that they are young, full of life, large barrelled, but small limbed, with a moderate sized head, and a good forehead. At the proper season my mares are covered by my ass-stallions, and they seldom miss. During the time the mares are in foal, I take care to have them fed with nourishing fodder, such as I imagine will most contribute to the size of the foal.

My expectations, after this management, are generally answered, for in due season my mares drop foals, which I could often sell for ten, and sometimes for twenty guineas a piece at three months old; and their future value is more in proportion increased afterwards.

I always house my mule colts the first winter; otherwise the hard frosts, and sharp, cold, long nights, would stint them in their growth, besides making them unshapely and rough.

From the time of their being dropped, I cause them often to be handled, to make them gentle: this prevents their hurting themselves by skittishness, and sudden frights; they are besides much easier broke at the proper age, and become docile and wonderfully harmless, having nothing of that viciousness which is so commonly complained of in these animals.

I have them for the most part broke at three years old, but never permit them to do much work till four; they are thus secure from being hurt by hard labour, till they have acquired strength enough to bear it without injury.

I have now several mules which I constantly employ in various kinds of labour; two, which are indeed very fine, I ride myself after my harriers; two more I keep for my huntsman, and one for my whipper-in: these are black, sorrel, and grey.

I have also four fine mules, but stronger and heavier than those above-mentioned, which I drive occasionally in a four-wheel chaise, besides several others less valuable, used for ploughing and carting.

Some of my neighbours smile at my taste; yet they cannot at the same time help acknowledging, that they are cheaper animals, when bred at home, as has been my practice, than horses.

Perhaps some of your readers, from the hints above thrown out, may be inclined to try the experiment: if so I would caution them against some errors I at first setting out fell into.

I thought at first I could not keep my colts too well during the winter months: accordingly I ordered that they should have the sweetest hay, which I had before ordered to be reserved for my cows, and as many oats as they could eat.

This way of feeding them, it is true, made them very fat; but it was far from being an advantage to them; for I afterwards found by experience, that it was not only incurring a much larger expence than was any ways necessary, but also made them wonderfully nice and delicate in their appetites ever after, and also by increasing their weight of flesh, made them more subject to strains and hurts in their morning gambols.

Finding this to be the case, I altered my method entirely, and contented myself with giving them food enough to prevent their losing flesh, and keep up their growth, without palling their appetites with delicacies, or making them over fat: as to the rest, I took the same care of defending

them from the injuries of the weather as ever, by allowing them stable room, and good litter to sleep on, besides causing them every day to be well rubbed down with a hard whisp of straw by an active groom, whose peculiar province it was to attend them; and this was scarcely ever omitted, particularly in cold, raw, wet weather, when they were least inclined to exercise themselves in the park. *Museum Rusticum*, vol. II. p. 162.

MULCH, straw half rotten.

MULLOCK, dirt, or rubbish.

MULLEIN, the name of a biennial plant, which perishes soon after it has perfected its seed. The leaves spread on the ground, are nine or ten inches long, and six broad, very woolly, of a yellowish white colour, and very little footstalk. The stem rises four or five feet high, and the upper part of it is garnished with yellow flowers, which sit very close, and form a thick spike. These flowers have an agreeable odour, appear in July, and the seeds ripen in autumn.

This plant commonly grows by the sides of highways, and on banks: but if it once gets into the fields in a warm exposure, and is suffered to seed there, it will soon overrun the whole ground. It may be easily destroyed by cutting off the stem, when it is in flower.

MURE, the cake of apples, grapes, &c. left in the press, after extracting the juice.

MURRAIN, or *Gargle*, a contagious disease among cattle.

The most remarkable murrain is that mentioned in the Philosophical Transactions, which spread through Switzerland, Germany, into Poland, &c.

The contagion seemed to propagate itself in form of a blue mist, which fell on the grass where the cattle grazed, when whole herds, forbearing their food, almost died away in twenty-four hours. Upon dissection were found large corrupted spleens, sphacelous and corroded tongues, &c. And even the persons who managed them were infected, and died like the beasts.

Some imagined it had its rise from noxious vapours thrown out of the earth, in three earthquakes perceived in the neighbourhood of the place where it began; though Dr. Slare thinks it rather owing to swarms of volatile insects.

The antidote for the sound, and medicine for the sick, was equal parts of foot, gunpowder, brimstone, and salt, with as much water as would wash it down: a spoonful was the dose.

The common signs of this disease are a hanging down of the head, gum at the eyes, as big as your finger, growing weakly, staggering, the head swelling very much, the breath short, the heart beating, with rattling in the throat; and if you put your hand into the creature's mouth, and find his breath very hot, and his tongue shining, the distemper is very strong.

As soon as you find any of your cattle infected, take a pretty large quantity of blood from them immediately, and give them a drench. Maddar root is highly commended for this distemper.

MUSHROOM, a genus of imperfect plants, composed of a pedicle crowned with a broad head, convex and smooth at the top; and hollow, foliated, lamellated, or pitted underneath.

It is of the utmost importance to distinguish the right eatable sort, from several noxious kinds that have been productive of even fatal accidents: the true sort appears at first with a roundish head, not unlike a button. The outside of this head is then very white, as is likewise the stalk on which it grows; but its under part, when it is taken off that stalk, from which it separates pretty easily, is of a livid flesh colour. Its flesh is also very white within. If this sort remains undisturbed, its head will spread to a considerable size, and open at the bottom, so as to form an almost flat surface, the under part of which will then be changed to a dark colour.

Most of the writers upon gardening have spoken so confusedly, not to say, of most of them, so unintelligibly, of the means of propagating this plant; that excepting the authors of the *Maison Rustique*, and Mr. P. Miller, one is sometimes puzzled to guess at their meaning. The account which this last has given in his Dictionary, is the most practical, being the method of the gardeners near London, who raise annually great quantities of mushrooms for sale. The substance of it is to the following effect:

The spawn of mushrooms, from which only they are pro-

propagated, looks like a white mouldiness shooting out in long strings. It is frequently found among the dung of old hot-beds, or in old dung-hills, especially when much litter has been mixed with these last, or the wet has not penetrated so as to rot it; or it may be procured by mixing some long stable dung, which has not been thrown up in a heap to ferment, with strong earth; and then laying this mixture under cover, where it cannot be wet, and where the air may be excluded from it as much as possible; for, the more effectually it is kept from air, the sooner the spawn will be produced. It will generally appear in about two months, if the heap has not been laid so close together as to heat (for that will destroy the spawn) and especially if it has been well covered with old thatch, or litter which has lain so long abroad as to have lost the power of fermenting. These are expedients by which the spawn of mushrooms may be procured at almost any time, by those who have not already had mushroom-beds in their gardens, and therefore cannot collect it from their remains: for there are but two months of the year in which it can be gathered from downs or pastures. These are August and September; when plenty of mushrooms spring up naturally in many of those places. To propagate them from thence, the ground should be opened about their roots, and such earth as is there found full of small white knobs, which are the offsets, or young mushrooms should be attentively gathered up, with as much care as can be, not to break the lumps or the earth about them. This seed, or rather this spawn (for if mushrooms have seeds, they are imperceptible to the eye) should be kept very dry till it is used: for the drier it is, the better it will take to the bed, as has been remarkably experienced by Mr. Miller, who declares, that he never saw these plants produced so soon, or in so great quantity, as from a percal of their spawn which had lain near the oven of a stove for upwards of four months, and was become so dry, that he despaired of its success.

The beds for mushrooms should be made of dung plentifully intermixed with litter, but not thrown in a heap to ferment. The best dung for this purpose is that which has lain spread abroad for a month, or longer. Their breadth should be about two feet and a half at bottom, their length proportioned to the desired quantity of mushrooms, and they should be made on dry ground, by spreading upon it, first a layer of dung about a foot thick, and upon this about four inches deep of strong earth; then a couch of dung, about ten inches thick, and upon that another layer of earth, contracting the surface of the bed all the way up, till it terminates like the ridge of a house. This may be done with three layers of dung, and as many of earth. When it is finished, it should be covered with litter, or old thatch, as well to prevent its drying, as to keep out wet, and after it has remained eight or ten days in this situation, it will be of a proper temperature to receive the spawn, for which its warmth should be but moderate. The thatch, or litter, should then be taken off, the sides of the bed should be smoothed, and a covering of light rich earth, by no means wet, should be laid all over it, about an inch thick. Upon this the spawn should be placed, by laying its lumps about two or three inches asunder, in such manner as to prevent their slipping down, and then the whole should be covered gently with about half an inch thick of the same light earth as was used before. The covering of litter should then be replaced over the bed, so thick as to secure it from wet, and to prevent its drying. If these beds are made in the spring or autumn, when the weather is temperate, the mushrooms will frequently come up in a month's time: but those which are made in summer, when the season is hot, or in winter, when it is cold, will not produce them so soon. Sometimes too it happens that neither of these beds, but most particularly those made in the summer or winter, yield any mushrooms before the end of five or six months; and that they then produce uncommon quantities, and continue in perfection for a long time.

The great art in managing of these beds is, to keep

them constantly in a due degree of moisture, and, above all, not to suffer them ever to receive too much wet; for that would inevitably destroy the spawn of the mushrooms. During the summer, they may be uncovered, to admit gentle showers of rain to them at proper times; and if the weather continues dry for a long while together, it will be right to water them gently now and then, but by no means to overdo it. During the winter, they must be kept as dry as possible, and closely covered, lest the cold air of the season should injure them. It will even be right in frosty or very cold weather, to lay over them a covering of dry litter, for it must not incline to ferment, and upon that some warm litter shaken from out of a heap of dung: This covering should also be renewed as often as it is found to decay, and, if the cold grows more severe, its thickness should be increased.

The mushrooms thus produced have a finer flavour than any that are gathered in the fields; and if the above directions are observed, they may be had in plenty during the whole year: for each single bed will continue good for several months, and yield great quantities if the spawn takes kindly.

When these beds are destroyed, the spawn for a fresh supply should be taken from them, and laid up in a dry place till the proper season for using it, which should not be sooner than five or six weeks, in order that it may have time to dry well, before it is put into the new bed; for otherwise there will be some danger of its succeeding.

MUST, new wine, or wort, before it is fermented.

MUSTARD is an annual plant raised from its seed only. The white mustard, as it is commonly called, is the sort chiefly cultivated in gardens, for a fallad herb in the winter and spring. The seeds of this are sown very thick in drills; either upon a border warmly situated, or if the weather be very cold, upon a gentle hot-bed, in the same manner as cresses and other small fallading, and in about ten days or a fortnight after the time of sowing, the plants will be fit for use; for when they are large and have rough leaves, they are too strong to be mixed with fallads.

The best way to save the seeds of this plant, is to sow a spot of ground with it in the spring, to thin the plants when they have about four leaves, and at the same time to hoe down the weeds, as is practised for turneps. This hoeing is to be repeated in about a month after, and the plants are then to be left about eight or nine inches asunder, which will be a sufficient space for the growth of this species. If these hoeings are well performed, in dry weather, they will keep the ground clean till the mustard seeds are ripe. The stalks of this plant, which are branched and hairy, will then be about two feet high, and the ripening of its seed is indicated by the pods changing to a brown colour; immediately after which they should be cut down, dried upon cloths, for two or three days, and then threshed out for use.

The larger sorts of mustard, the seeds of which are used chiefly for sauce, are to be treated in the same manner; excepting that, as they grow much larger, a proportionably greater space must be left between their plants: and as their seeds will not ripen so soon as those of the smaller kind, three hoeings, or rather good deep stirrings, of the ground may be requisite for them. One of these large sorts, which is the common mustard, grows naturally in many parts of England; but is cultivated in the fields for its seeds, of which the sauce called mustard is made; and another sort, which naturally grows in our arable lands, and is also cultivated for use, produces the seeds which are commonly sold under the appellation of Durham mustard-seeds. The stalks of the last sort seldom rise above two feet high; but those of the former generally run up to the height of four or five feet.

Mr. Young, in his *Annals of Agriculture*, vol. II. says, "that mustard seed sometimes turns out prodigiously profitable, that is, three or four, and even five quarters, at 4/ a quarter. But it is hazardous, and has a very great evil of rising afterwards in successive crops, and is hardly ever completely eradicated."

N.

NAIL, or *Naile*, the weight of eight pounds.

NAPE, or *Neap*, a piece of wood with two or three with which they support the fore part of a loaded wain.

NASTURTIIUM. See the article **CRESS**.

NAVEL-GALL, is a bruise on the back of a horse, or pinch of a saddle behind, which if left alone long will be hard to cure.

The hurt obtains this name, because it is over-against the naval. The cure :

Take oil of bay, oil of costus, fox-grease, oil of favin of each an ounce ; a handful of great garden worms ; scour them with salt and white wine, and put all the ingredients together into an earthen pipkin ; stop or cover it very close, and boil them well ; then add an ounce and a half of fallad oil ; set it upon the fire again, and boil it till it becomes a perfect ointment, which strain into a gallipot : warm it when you use it, and so dress the sores with lints or hards dipt in it.

If the place be only swelled, and the skin not broken, then rub it with your hand, or a rag dipped in brandy, and it will take it down.

NAVE of a Wheel, is that short thick piece in the center of the wheel, which receives the end of the axle-tree, and in which the ends of the spokes are fixed ; it is bound at each end with hoops, called the nave bands ; it has likewise in each end of the hole, through which the end of the axle-tree goes, a ring of iron called the wisher, which saves the hole of the nave from wearing too big.

NEAT ; black cattle, oxen.

NECK of a horse, should be lean, and but little flesh upon it ; and to be well shaped, it should, at its going from the withers, rise with a slope upwards, diminishing by degrees toward the head.

In mares, it is a good quality to have their necks somewhat gross, and charged with flesh, because their necks are generally too fine and slender.

Deer necks, cock-thropled, are those, in which the flesh that should be next the mane, is set below, and next the throat, which renders the neck ill-shaped and ugly.

A well-shaped neck contributes very much to the making him light or heavy of the hand, according as it is fine or coarse.

NETTLE, the name of a weed well known, and which may be easily destroyed by cutting the roots, before the plant has perfected its seed.

NEWING, yeast, or barm.

NICKING, the name of an operation often performed on the tails of saddle-horses, and by which means they carry them in a more beautiful manner.

Before we describe the operation of nicking, it may be necessary to enquire how the effect of it (the elevation of the tail) is brought about ; and in order to know this, and judge with propriety of the operation, we must consider the tail as elevated or lifted up by one set of muscles, and depressed or pulled down by another.

It is somewhat remarkable, that Snape, Saunier, and Gibson, who are in general pretty exact in their anatomical descriptions, should omit, in their account of the muscles of a horse, to describe those of the tail ; for which reason, as a proper opportunity has not offered, to supply this omission by making a compleat dissection with that accuracy we could have wished, it is hoped the subsequent imperfect description will be excused, as it was taken only from a tail that was dissected after docking.

Here we observed, that the muscles which elevate the tail, are more numerous, large, and strong, than those that depress it ; that they are closely connected to the bones of the tail by fleshy fibres, and terminate in strong tendons at the extremity ; that the muscles of the latter soon form into tendinous expansions, and besides three large tendons,

which are inserted into the latter bones of the tail, there are several other small tendons, which run laterally, whose use most probably is to move the tail sideways : the arteries are four in number, and run sometimes above the bones of the tail, consequently easily avoided by a dextrous hand, as they cannot readily be wounded by the knife, in dividing the tendons necessary to be cut in this operation.

The art of nicking horses then chiefly consists in a transverse division of these depressing tendons of the tail, and such a position afterwards as will keep their extremities from coming again into contact ; so that an intervening callus fills up the vacuity : by these means an additional power is given to the antagonist muscles, viz. the elevators ; the counteraction of the depressors being manifestly abated by the division of the tendons, and the intervention of the callus.

The usual method of supporting the tail by a pulley and weight, is liable to many exceptions, the extremities of the divided tendons not being by that method kept sufficiently asunder ; the situation of the tail being rather inclined to a perpendicular than a curved direction : this position too is liable to many variations, from the different movements of the horse, and is the reason that the tail frequently inclines to one side, as the nick may heal up faster on one side than the other ; the disagreeable situation the horse must stand in, with a weight consequently hanging to his tail, is another material objection, besides the necessity of removing it when the horse is exercised, or taken out to water.

To remedy these inconveniences, and perfect this operation, a very ingenious gentleman, who had thoroughly considered it, has been so kind as to favour us with a draught and description of a machine he contrived for that purpose, which has frequently been practised with the expected success, and indeed at first view appears in every respect calculated to correct all the defects in the old one : as we doubted not its reception being perfectly agreeable to the public, we have ordered a plate to be engraved, which, with the annexed description, will, we hope, make it very familiar and intelligible to every capacity.

In regard to the operation, it is worth notice, that the extremities of the tendons, which jut out in the operation, need not here be cut off, as is customarily done ; the number of the incisions must be in proportion to the length of the tail, but three in general are sufficient. The most approved method of dressing at first, is with powdered rosin, and spirit of wine, applying a soft dossil of lint or tow, dipped in the same, between each nick, and lapping the tail up with a linen cloth and broad fillet ; which the next morning should be cut open down the back part of the tail, and the morning after be gently taken off : when it will be proper to plat the hairs, in order to keep them clean, and to set the tail, as will be directed in the plate and references.

Every two or three days, the tail should be let down, and the upper part next the rump bathed with hot vinegar, and if it begins to crack, and the hair comes off, a little tincture of myrrh will soon put a stop to it. To obviate any threatening symptoms that may arise in regard to the wounds, have recourse to the remedies used in docking.

After six or eight days, it will be proper to let the horse stand without the machine for a few hours, and then be rode about in order to observe how he carries his tail ; by which means you will the better judge how to fasten it down, whether to confine it closer, or give it more scope : after the wounds are healed up, it may be necessary to keep the tail suspended, till the callus is confirmed, at least for some hours in the day, though a greater liberty may now be allowed it.

Thus this machine answers every intention, is far preferable to the pulley, as it keeps the tendons properly separated, and the tail in a certain position ; so that the wounds heal up uniformly, without any risk of its inclining to one side ; the

the horse also is more at ease, having no weight constantly pulling and teasing him, and may be taken out to water or exercise without any inconveniency, or disturbance.

Directions for the Application of the Nicking Machine; and Explanation of the Plates.

When the hair of the tail is properly platted, and tied with a knot or two at the end, the pad, &c. as described in Plate XX. fig. 9. must be put on, and the machine, as in fig. 10. buckled to them, letting the part G in the machine lie over the part of the tail that joins to the horse's rump; then let an assistant, standing on the side rail of the brake, or any other conveniency that may place him above the horse, raise the horse's tail very gently till the knot of the tail gets so far beyond the strings L L in fig. 10. that it may be tied down; which being done, the tail may be let down lower, or taken up higher at pleasure. It is to be observed, that the ligature is not made on the tail itself, but on the platted hair, at the extremity of the stump.

The machine, fig. 10. must be made of a piece of tough wood about a foot long, viz. from A to B, and about nineteen inches broad from C to D, and seven or eight inches thick. The under part must be hollowed, so as to let in the horse's rump, and that the wings C D may rest on his buttocks. To receive the tail a groove must be cut from G to H, about three inches wide, and three deep at G, lessening gradually both in height and breadth to H. Holes must be made at certain distances in the groove, as at H, for the string, and a nick cut to receive the billet from the strap K. Two buckles fixed to the machine as at I I.

The pad, &c. are sufficiently described in fig. 9. and its references: the wood must be sloped off from E to C and A, and so on the other side, to lighten the machine, and hallowed at B, G, and F.

Fig. 9. represents a horse, with his tail in the frame or machine. A is a pad, to which is fastened a circingle B, C C two side straps, one on each side the horse, fastened to the circingle, to keep the machine from going to either side; D, a breast-plate to prevent the pad, &c. slipping back. E, a strap fixed to the pad, and buckling to the machine to keep the tail on the stretch at pleasure. F, the string tied on the hair, to confine the tail down to the machine.

Fig. 10. from A to B is twelve inches; from C to D, measured with a string drawn over E F, is nineteen inches. From the top of the groove at E to the bottom G, is three inches. From E to F, the widest part of the groove, three inches, gradually narrowing as the tail lessens to its extremity. The dots about H are holes in the groove, through which a piece of tape or pack-thread must be put, according to the length of the dock, and the distance of the knot to tie the tail down behind the knot. I I, the buckles to receive a strap from the circingle on each side, as described in fig. 9. which keeps the machine from turning to either side. K, the strap with a billet and buckle, which comes along the back from the pad, and is fastened to the machine, through a nick cut just above H. L L, the strings to tie down the tail. B, G, F, the hollow to let in the rump.

Fig. 11. represents the horse with the machine on, standing directly before you, where the depth of it is shewn, being three inches.

C D, the extremities of the wings. E F, the upper part. *Bartlet's Farriery, p. 325.*

NIGHT-FALL; the beginning of night.

NIGHT-MARE. A malady incident to horses as well as the human species, proceeding from the melancholy blood oppressing the heart: it will cause the horse to sweat more in the night than in the day, and thereby deprive him of his rest.

You may discover it by observing him in the morning, whether he sweats on the flanks, neck, and short ribs, which are sure indications of it.

For the cure:

Take a pint of fallad oil, a quarter of a pound of sugar-candy, put into them a handful of salt, mix them well together, warm them blood-warm, and give it the horse two mornings.

NINE-PIN COLLARS. See COLLARS.

NIPPERS, are four teeth in the fore-part of a horse's

mouth, two in the upper and two in the lower jaw: a horse puts them forth between the second and third years.

NOPE, a bull-finch, or red-tail, a small singing bird, well known.

NURSERY. Mr. Young, in his *Annals of Agriculture* Vol. III. inserts the following information, (by the Rev. Mr. Swayne. Mr. William Boucher, of Edinburgh, in his preface to his *Treatise on Forest Trees*, has the following observations: "It has been an almost universally received opinion, that trees ought to be raised in the nursery on a poorer soil than that to which they are afterwards to be transported for good, and it has been directed by many, otherwise the most respectable authors. I must acknowledge this doctrine has a very specious appearance at first view. I adhered to it early in life, and it is so seemingly consistent with nature, that I am not surprised it has been generally adopted by young planters: at the same time, I cannot account for those who have had much practice and long experience not exposing the errors of it.

"In the following lines, I have given some examples, from frequently repeated experiments, of the ill effects I have felt by planting young and tender seedlings in the poorest soils, and the greater success attending those that were well-grown, on the same, or in similar situations. The consequences of raising plants on poor hungry land, are no less fatal than planting the seedlings in such, and should as much as possible be avoided. I have mentioned, in the culture of many trees, the necessity of promoting their vigorous growth at first, in order to their becoming stately and handsome; nor can this be effected by any other means than being early nursed in generous soil, for whatever future purpose they are meant, or to whatever situations they are destined, and that, if they are but barely supported from infancy on meagre ground, they will never afterwards become strong, though removed to that which is rich and feeding." In chapter 40, p. 252, of the *Treatise*, he says, "I have sown the seeds of forest trees on the poorest ground, planted seedlings, and strong well-nursed trees, from five to ten feet high, on the same ground, and at the same time, where the old well cultivated plants have frequently made goodly trees, when the seedlings have perished, and from the sterility and coldness of the soil, the seeds have not so much as vegetated. In short, the roots of seedlings are not so well fitted as larger plants to draw sufficient nourishment from crude, rank, and uncultivated soils: and as I have truly found what is here said, in many instances to be the case, I am obliged to believe that the general practice of planting seedlings in poor, and large trees in good, land, should be quite reversed."

Mr. Anderson, of Monkhill, Aberdeenshire, in his very ingenious and scientific *Essays on Agriculture and Rural Affairs*, sect. 6, p. 24. vol. 1. 2d edit. says: "Almost all writers on agriculture advise the farmer to be very careful to make choice of such plants only as have been raised in a nursery of a poor soil; and always to reject such as have been reared in a richer soil than that in which he is to plant them: because, say they, a plant which has been reared in a barren soil has been inured, from its infancy, to live hardily, and will advance with a great degree of luxuriance, if it is planted in one that is better: whereas a plant that has been nursed in a fertile soil, and has suddenly rushed up to a great size, like an animal that has been pampered with high feeding, and swelled up with fat, will languish and pine away, if transplanted to a more indigent soil.

"It would be no difficult matter to shew the fallacy of this mode of reasoning, and to point out many errors which have crept into almost all sciences, from pursuing such fanciful analogies between objects, in their own natures so different, as in this example. But as this would be in some measure foreign to my aim in this essay, I shall content myself with observing, that it could seldom be attended with worse consequences than in the present case, as it leads to a conclusion directly the reverse of what is warranted by experience. For I have found, from reiterated experiments, that a strong and vigorous plant, that has grown up quickly, and arrived at a considerable magnitude in a very short time, never fails to grow better after transplanting; than another of the same size that is older and more stunted in its growth, whether the soil in which they are planted, be rich or poor: so that instead of recommending a poor hungry soil for a nursery, I would, in all cases, wish to set apart for this purpose, the richest and most fertile spot that could be found; and in the choice of plants, would always prefer the youngest

youngest and most healthy, to such as were older, if of an equal size. I speak here from experience, and therefore do it without the smallest doubt or hesitation, being certain that future observations will confirm the justness of these remarks."

"In page 8, of the same Number of these Annals, Monf. Mournon, in his directions concerning the cultivation of carrots, observes, after sowing the seed, that the field should then be harrowed and rolled smooth." Query, should not the roller precede the harrow? In the garden-culture of these roots it is the constant practice, and recommended by the most approved writers on gardening, after sowing to tread the ground, and then to rake in the seed. I was long averse to this method, as thinking the ground

ought to be left in as light and open a state as possible, that the roots might have the more room to swell, till a constant failure in my crops impelled me to try the common method, the consequent success of which has obliged me to continue the practice.

"Notwithstanding M. Mournon's advice to roll often, after the plants are come up, with a view to prevent the too great luxuriance of the greens, has rather an unphilosophical appearance (as you observe), yet I myself often remarked, that those plants which have uncommonly large tops, have always the worst roots." See ORCHARDS, and PLANTING.

NUSHED, starved in bringing up.

O.

OAK, a tree well known, and one of the principal materials in building ships, &c. being strong in all positions.

All the sorts of oaks are propagated from acorns, which should be sown as soon as possible after they are ripe; for if they are kept too long out of the ground, they seldom grow.

The manner of sowing these acorns, if designed for a small plantation, or to be removed, is, to prepare some beds of fresh earth, neither too strong and heavy, nor too light and dry; in these beds you should place the acorns in rows one foot asunder, and about two inches distance in the rows, covering them about two inches thick with the same fresh earth; observing to leave none of them uncovered, to entice the vermin, which may in a short time destroy all the seeds.

In the spring, when the plants begin to appear, you must carefully clear them from weeds; and if the season proves dry, you should refresh them now and then with a little water, which will greatly promote their growth. In these beds the plants should remain until the following autumn, observing constantly to keep them clear from weeds; at which time you should prepare a spot of good fresh earth, in size proportionable to the quantity of plants, which should be trenched and levelled: then towards the middle or latter end of October, you should carefully take up the plants, so as not to injure their roots, and plant them out in rows three feet asunder, and eighteen inches distance plant from plant; observing never to suffer the plants to abide long out of the ground, because their roots would dry, and endanger the growth of the plants.

When they are planted, you should lay a little mulch upon the surface of the ground, near the roots, to prevent the earth from drying too fast: and if the season should prove very dry, you should give them a little water to settle the earth to their roots.

When the plants have taken root in this nursery, they will require a little more care than to keep them clear from weeds, and dig the ground between the rows every spring; in doing of which, you should cut off such roots as extend very far from the trunk of the trees, which will render them better for transplanting again: you should also prune off such side-branches as extend themselves very far, and would retard the upright shoot; but you should by no means cut off all the small lateral branches, some of which are absolutely necessary to be left on, to detain the sap for the augmentation of the trunk; for I have often observed, where trees have been thus closely pruned, that their heads have overgrown their bodies, so that they have bent downward and become crooked.

When these trees have remained in the nursery three or four years, they will then be large enough to transplant to the places where they are to remain; for it is not proper to let them grow very large before they are planted out; because they are very hazardous trees to remove when old, or after they have taken deep root.

The season for this work is, as I said before, in the autumn; at which time, if they are carefully taken up, there will be little danger of their succeeding. When they are

planted, the surface of the ground should be mulched about their roots, to prevent its drying too fast; and if the season is very dry, they should be watered, to settle the earth to their roots, which may be repeated two or three times in very dry weather; but you must carefully avoid giving them too much water, which is very injurious to these trees, when newly removed.

You should also stake them, to prevent their being shaken and disturbed by the winds, which would retard their rooting. In transplanting of these trees, you should by no means cut their heads, which is too much practised: all that should be done, must be only to cut off any bruised or ill-placed branches, which should be taken off close to the place where they are produced: but there can be no greater injury done to these trees than to shorten their shoots; for when the leading bud, which is absolutely necessary to draw and attract the nourishment, is taken off, the branch often decays entirely, or, at least, down to the next vigorous bud.

The trees, thus raised and managed, will, if planted in a proper soil, grow to a considerable magnitude, and are very proper for a wilderness in large gardens, or to plant in clumps in parks, &c. but if they are designed for timber, it is much the better method to sow the acorns in the places where they are to remain; in order to which, you should provide yourself in autumn with a sufficient quantity of acorns, which should be always taken from straight, upright, vigorous growing trees; these should be gathered from under the trees as soon as may be after they are fallen, and, if possible, in a dry time, laying them thin in some open room to dry; after which they may be put in dry sand, and preserved in a dry place until the end of November, when you should prepare the ground for planting them.

The directions here given are designed only for small plantations in a garden or park, which are only for pleasure; but where these trees are cultivated with a view to profit, the acorns should be sown where the trees are designed to grow; for those which are transplanted will never grow to the size of those which stand where they are sown, nor will they last near so long sound: for in some places, where these trees have been transplanted with the greatest care, and they have grown very fast for several years after, yet they are now decaying, when those which remain in the place where they come up from the acorns are still very thriving, and have not the least sign of decay: therefore, whoever designs to cultivate these trees for timber, should never think of transplanting them, but sow the acorns on the same ground where they are to grow; for the timber of all those trees which are transplanted, is not near so valuable as that of the trees from acorns. I shall therefore add some plain directions for the sowing of acorns, and managing of the young trees, during their minority, until they are out of danger, and require no farther care.

The first thing to be done is that of fencing the ground very well, to keep out cattle, hares, and rabbits; for if either of these can get into the ground, they will soon destroy all the young trees. Indeed, they will in a few years

years grow to be out of danger from the hares and rabbits; but it will be many years before they will be past injury from cattle, if they are permitted to get into the plantation; therefore, durable fences should be put round the ground. If, in the beginning, a pale-fence is made about the land, which may be close at the bottom, and open above; and within the pale a quick-hedge planted, this will become a good fence, by the time the pale decays, against all sorts of cattle; and when the trees will have got above the reach of hares and rabbits, so that they cannot injure them; for the bark of the trees will be too hard for them to gnaw.

After the ground is well fenced, it should be prepared, by ploughing of it three or four times, and, after each ploughing, to harrow it well, to break the clods, and cleanse the ground from couch, and the roots of all bad weeds. Indeed, if the ground is green sward, it will be better to have one crop of beans, pease, or turneps, off the ground, before the acorns are sown, provided these crops are well hoed to stir the surface, and destroy the weeds: for if this is observed, the crop will mend and improve the land for sowing; but in this case the ground should be ploughed as soon as possible, when the crop is taken off, to prepare it for acorns; which should be sown as soon as may be after the acorns are ripe: for although these may be preserved in sand for some time, yet they will be apt to sprout; and, if so, the shoots are in danger of being broken and spoiled; therefore we would advise the sowing early, which is certainly the best method.

In making choice of the acorns, all those should be preferred which are taken from the largest and most thriving trees; and those of pollard trees should always be rejected, though the latter are generally the most productive of acorns; but those of the large trees commonly produce the strongest and most thriving plants.

The season for sowing of the acorns being come, and the ground having been ploughed, and levelled smooth, the next work is to sow the acorns; which must be done by drawing of drills across the ground, at about four feet asunder, and two inches deep; into which the acorns should be scattered, at two inches distance. These drills may be drawn either with a drill-plough, or by hand, with an hoe; but the former is the most expeditious method; therefore in large plantations should be preferred. In the drawing of the drills, if the land has any slope to one side, these should be made the same way as the ground slopes, that there may be no stoppage of the wet by the rows of plants crossing the hanging of the land. This should be particularly observed in all wet ground, or where the wet is subject to lie in the winter. When the acorns are sown, the drills should be carefully filled in, so as to cover the acorns securely; for if any of them are exposed, they will entice the birds and mice; and if either of these once attack them, they will make great havoc with them.

The reason of my directing the drills to be made at this distance, is for the more convenient stirring of the ground between the rows, to keep the young plants clean from weeds: for if this is not carefully done, it cannot be expected that the young plants should make much progress; and yet this is generally neglected by many who pretend to be great planters, who are often at a large expence to plant, but seldom regard them after: so that the young plants have the difficulty to encounter the weeds, which frequently are four or five times the height of the plants, and not only shade and draw them, but also exhaust all the goodness of the ground, and consequently starve the plants: therefore, whoever hopes to have success in their plantations, should determine to be at the expence of keeping them clean for eight or ten years after sowing, by which time the plants will have obtained strength enough to keep down the weeds: the neglecting of this has occasioned so many young plantations to miscarry as are frequently met with in divers parts of England.

About the end of March, or beginning of April, the young plants will appear above ground; but before this, if the ground should produce many young weeds, it will be good husbandry to scuffle the surface over with Dutch hoes, in a dry time, either the latter end of March, or the beginning of April, to destroy the weeds, whereby the ground will be kept clean, until all the plants are come up so far as to be plainly discerned; by which time it may be proper to hoe the ground over again; for by doing it early, while the weeds are small, a man will perform more of this work in one day than he can in three or four when the

weeds are grown large: besides, there will be great hazard of cutting off or injuring the young plants, when they are hid by the weeds; and small weeds, being cut, are soon dried up by the sun; but large weeds often take fresh root, and grow again, especially if rain should fall soon after, and then the weeds will grow faster for being stirred; therefore it is not only the best method, but also the cheapest husbandry, to begin cleaning early in the spring, and to repeat it as often as the weeds are produced.

The first summer, while the plants are young, it will be the best way to perform these hoeings by hand; but afterwards it may be done with the hoe-plough; for as the rows are four feet asunder, there will be room enough for this plough to work; and as this will stir and loosen the ground, it will be of great service to the plants; but there will require a little hand labour where the plough is used, in order to destroy the weeds, which will come up in the rows between the plants; for these will be out of the reach of the plough, and, if they are not destroyed, they will soon overgrow and tear down the young plants.

After the plants have grown two years, it will be proper to draw out some of them, where they grow too close; but in the doing of this, great care should be had not to injure the roots of those left; for as the plants which are drawn out are only fit for plantations designed for pleasure, so these should not be so much regarded in their being removed, as to sacrifice any of those which are designed to remain. In the thinning of these plantations, the plants may, at the first time, be left about one foot asunder, which will give them room enough to grow two or three years longer; by which time it may be easy to judge which are likely to make the best trees. Therefore these may be then fixed on, as standards, to remain; though it will be proper to have a greater number at this time marked than can be permitted to grow, because some of them may not answer the expectation; and, as it will be improper to thin these trees too much at one time, so the leaving double the number intended at the second thinning will not be amiss. Therefore, if they are then left at about four feet distance in the rows, they will have room enough to grow three or four years longer; by which time, if the plants have made good progress, their roots will have spread over the ground; therefore it will be proper to take up every other tree in the rows. But, by this, I do not mean to be exact in the removing, but to make choice of the best plants to stand, which ever rows they may be in, or if they should not be exactly at the distance here assigned: all that is designed here, is, to lay down general rules, which should be as nearly complied with as the plants will permit: therefore every person should be guided by the growth of the trees in the performance of this work.

When the plants have been reduced to the distance of about eight feet they will not require any more thinning. But in two or three years time, those which are not to remain will be fit to cut down, to make stools for underwood; and those which are to remain, will have made such progress as to become a shelter to each other; for this is what should principally be attended to, whenever the trees are thinned; therefore, in all such places which are much exposed to the wind, the trees should be thinned with great caution, and by slow degrees; for if the air is let too much at once into the plantation, it will give a sudden check to the trees, and greatly retard their growth; but, in sheltered situations, there need not be so great caution used as in those places; the plants will not be in so much danger of suffering.

The distance which I should chuse to allow to those trees which are designed to remain for timber, is, from twenty-five to above thirty feet, which will not be too near, where the trees thrive well; in which case their heads will spread, so as to meet in about thirty, or thirty-five years: nor will this distance be too great, so as to impede the upright growth of the trees. This distance is intended that the trees should enjoy the whole benefit of the soil. Therefore, after one crop of the underwood, or, at the most, two crops are cut, I would advise the stubbing up the stools, that the ground may be entirely clear, for the advantage of the growing timber, which is what should be principally regarded: but, in general, most people have more regard for the immediate profit of the underwood than the future good of the timber, and, frequently, by so doing, spoil both: for, if the underwood is left after the trees have spread so far as that their heads meet, the underwood will not be of

much worth ; and yet by their stools being left, they will draw away a great share of nourishment from the timber-trees, and retard them in their progress.

The soil in which oak makes the greatest progress, is a deep rich loam, in which the trees grow to the largest size ; and the timber of those trees which grow upon this land, is generally more pliable than that which grows on a shallower or drier ground ; but the wood of the latter is much more compact and hard. Indeed there are few soils in England in which the oak will not grow, provided there is proper care taken in their cultivation ; though this tree will not thrive equally in all soils : but yet it might be cultivated to a national advantage upon many large wastes in many parts of England, as also to the great profit of the estates where these tracts of land now lie uncultivated, and produce nothing to the owner. And, should the present temper of destroying the timber of England continue in practice some years longer, in the same degree which it has for some years past, and as little care be taken to raise a supply, this country, which has been so long esteemed for its naval strength, may be obliged to seek for timber abroad, or be content with such a naval strength as the poor remains of some frugal estates may have left growing : for as to the large forests, from whence the navy has been so long supplied, a few years will put an end to the timber there ; and how can it be otherwise, when the persons to whose care these are committed, reap an advantage from the destruction of the timber ? *Miller's Gard. Dict.* See TIMBER.

Mr. Marshall, in his Rural Economy of Norfolk, vol. II. says, that "oaks are observed to grow best, and make the finest plants and the most beautiful trees, when they are raised undisturbed from the acorn. The oak having naturally a strong tap-root, it is almost certain death to remove a large plant which has not been transplanted or tapped whilst young : nevertheless, if the tap-root has been properly taken off from the seedling plant, it may afterwards be removed at pleasure, with safety.

"Oaks may be tapped by taking up the plants and taking off the tap-root with a knife, or it may be done as they stand, with a tapping iron, or even a common spade ground to an edge. This, being introduced at a proper depth beneath the surface of the ground, cuts off the tap-root ; leaving the principal part of the lateral horizontal fibres undisturbed. When the plants have got large (four or five years old for instance), this is perhaps the safest way of treating them ; for the lateral shoots in this case receive no check whatever, but continue to throw up a regular supply of sap to the plant : whereas, by taking them up and removing them into a fresh situation, they are several days before they begin to work ; in which time the plant may receive irrecoverable injury.

"A seed-bed of oaklings, five years old, I treated in this manner : in March and April I tapped them all with common spades, ground sharp ; pruned such as were in any degree straight ; and headed down the rest near the ground, to throw out straight shoots to be trained.

"Not a plant I see is dead.

"Had there been more of them cut down the effect would have been still better.

"A striking instance of success in transplanting large oaks for standards occurs on Gunton Common. Scarcely a plant, of some thousands, has miscarried, and very few which do not flourish.

"A person who had some share in the business of this plantation, tells me, that it was the employment of two men and a couple of horses, almost all the first summer after they were planted, to water them ; not by a pailful, but by a hoghead, at once ; which served for the summer.

"This was a rational method ; a pailful only tantalises and baulks the plant ; whereas a hoghead deposited at its root affords a natural and regular supply, to be drawn up leisurely by the sun during the course of the summer."

Mr. Marshall, also observes, that "upon some estates it is the practice to put in, when a new hedge is planted, a holly at every rod, and an oak-plant at every two or three rods, among the white-thorn layer. This is an excellent practice, provided the young oaks be trained to a proper height before they be suffered to form their heads. For, in this case, they will become a valuable source of timber, without injuring, in any material degree, the inclosures they grow between. It is the roots of the ash and elm, and the tops of low pollards, and tall overgrown hedge-woods, which are injurious to the farmer. A timber-oak, of fifteen to twenty feet stem, does very little if any injury either to the crop, or the hedge growing under it.

"But if, on the contrary, the oaklings, thus planted, be suffered to rise with more than one stem, as stubwood, or, rising singly (which is seldom the case in a young hedge), they be permitted to form their heads at eight or ten feet high, with flat wide-spreading tops, they lose their intended value, and become nuisances, not only to the adjoining inclosures, but to the hedge in which they grow. Eligible, therefore, as it is to plant young oaks among hedgewood, the advantage to be obtained from it rests wholly on the after-management."

Mr. Young, in his Annals of Agriculture, vol. I. says, that "oaks are of slow growth, but if you put them at proper distances amongst the quick growing trees, they will sometimes be drawn up beyond your expectations, and let me caution you to watch them, and to cut out such trees as crowd upon them, by transplanting them every third year in a nursery ; they may be put out from six to ten feet high.

"Land that will let at from 12s. to 18s. per acre, for any given time, pays better than with wood, if you calculate the compound interest on the annual rent ; but who is there that is so careful as to make it, or that can make it on very small sums ? I consider the appropriating of 50 acres out of every thousand, as laying by a small part of the income of an estate, that will not be missed, at compound interest, as an accumulating fund, that frequently comes in very seasonable to stop a large gap.

"I have now, of my grandfather's sowing, about 26 acres of as fine young oak timber as can be seen, which may be worth, in 25 or 30 years, 4000l. I have likewise, of my father's sowing, 20 acres to succeed them. My ancestors have done so much : I have only added about ten acres to the fund, chiefly of Scotch fir, on a poor soil, where other trees have been tried, and failed ; the thinning of these woods likewise pay a fair rent, after a time. I made a purchase, upon which were 14 acres of wood-land ; there are 400 oak trees upon it, that, in 30 years from the time of purchase, will sell for as much as the estate cost me, 1000l.

"If you could find situations adapted to the tree, popular pays beyond any other ; but they require a deep loamy soil by the side of a stream. My father felled two in the year 1760, of 45 years growth ; they sawed to 2200 feet of inch boards, which would now be worth 16s. 4d. per hundred ; deduct 2s. 4d. for sawing, remains nett profit 15l. 8s. In 1761, my father planted a clean shoot of poplars, about ten feet long, which girthed, in December 1770, four feet four inches, and in October 1775, five feet five inches, and at this time, is, at three feet from the ground, six feet seven inches ; within two yards of it stands another of the same age, that measures five feet five inches and a half, and, I think, in the end, will be a larger tree ; they are at least 60 feet high. Poplars should never be shredded up.

"A gentleman that farms, and keeps a waggon team, should have 120 or 130 acres of land."

The Cowthorp oak, the largest in England, is 36 feet, 6 inches circumference, 5 feet from the ground. The oak in Holt-forest, near Bentley, at 7 feet 34 in circumference. The Fairtop oak seemingly found in 1754 ; and the earl of Thanet's, in Whinfield park, Westmoreland, 31 feet 9 inches. The handsomest in England, is in the earl of Powis's park, by Ludlow, which, in 1757, was 16 feet 3 inches ; but straight and clear for 60 feet. The Dunbarton ash 16 feet 9 inches. A Wych elm at Bradley, in Suffolk, 26 feet 3 inches. Lord Ducie's chestnut, at Totworth, in Gloucestershire, at 6 feet, was 46 feet 6 inches in 1759, it is above 1100 years old. It was called the great chestnut in King John's time ; Mr. Marsham calculates, that it was 540 years old when he came to the throne, and was 11 yards in circumference. See BATH MEMOIRS, vol. I p. 76.

OAK-BARK. See the article BARK and TAN.

OATS, the name of a well known species of grain, and of which Mr. Miller reckons four sorts, cultivated in England, viz. the white, the black, the brown, or red, and the naked oat, in which, though supposed to be only accidental varieties, he has never observed any alteration where they have been cultivated separately for many years. Their principal difference is in the colour of their grain.

The white sort, which is most common about London, makes the whitest meal, and is chiefly cultivated where the inhabitants live much upon oat-cakes. The black oat is more cultivated in the northern parts of England, and is esteemed a very hearty food for horses. Red oats are much cultivated in Derbyshire, Staffordshire, and Cheshire, but are

are seldom seen in any of the counties near London; though, as they are a very hardy sort, and yield a good increase, they will be well worth propagating, especially in all strong lands. The straw of these oats is of a brownish red colour, as is also the grain, which is very full and heavy, and esteemed the better food for horses than either of the other sorts. The naked oat is least common in the southern parts of England; but in the northern counties, in Scotland, and in Wales, it is pretty much cultivated, and is particularly esteemed, because its grain threshes clean out of the husk, and need not be carried to the mill, to be made into oat-meal or grist.

As oats are very hardy and will thrive in almost any soil, they have been a great improvement to many estates in the northern parts of this kingdom, where, though sown even so late as April, and in stiff ground, they have ripened early, and yielded a good crop. However, February or March, according as the season proves early or late, is a more common and better time for sowing this corn, of which it may always be right to sow the largest grain sort earliest.

Oats are often sown after a crop of wheat, rye, or barley; in which practice the common method is to turn in the stubble, with one ploughing, about the beginning of February, and sow the seed with a broad-cast at twice, harrowing it in, once after the sowing, and five or six times after the second, observing to draw the harrow once or twice across the furrows, to break the clods and cover the seeds: but at the other times to harrow in the same direction as the furrows, lest the stubble should be raised on the surface. But it would be much better husbandry to plough in the stubble in autumn, that it may rot in winter, and to give the land another ploughing, and a good harrowing just before the oats are sown. This will render the ground finer, and fitter to receive the grain, the increased produce of which will amply repay the extraordinary expence of tillage. M. Duhamel, after observing that every farmer knows, though but few practise it, that all crops of spring-corn are greatly bettered by this method, instances the example of M. d'Elu, one of his correspondents, who having given three ploughings to some of his oat-lands, had in 1759, a year remarkably dry, and unfavourable to spring-corn, a plentiful crop of oats, which held up well till they were perfectly ripe, and yielded excellent grain.

Another thing, which I must also insist on, is, that if farmers were to follow the directions before given, in regard to the changing of crops, by which means oats, which impoverish the ground, would always succeed some one of the meliorating crops, the return would be much more plentiful than in the common way, because the earth would be in a much looser state.

When oats, as it frequently happens, are sown upon lay, or on ground newly broken up, after only one ploughing, which is given in January, when the earth is moist, to turn down the sward; the harrowing must be in the same directions as the furrows, or but very little across, for fear of raising the turf. But this again is bad husbandry: for the ground would be brought to a much better tilth for other grain, as a preparation, for which this sowing is chiefly intended, by giving the sward time to rot before the oats are sown; because the roots of the grass will prevent those of the corn from striking downward.

Black oats delight in a moister soil than the white sort, and, being a hardier plant, may be sown a month earlier. The white, which prefer a dry land, and will do well on gravel and sand, are the best of all corn for ground subject to quick-grass or weeds, because it may be ploughed later for them, and they rise sooner, and top the weeds better than black oats. The weather cannot be too dry when white oats are sown; though the ground may then be moister for them than barley will endure; because this last, having a thinner coat, is soon killed by imbibing the wet, which may perhaps burst many of its vessels; whereas, white oats, being protected by a double husk, better resist the entering of the moisture. Mr. Lisle, who makes these remarks, adds, that according to the best of his observations, white oats require a rich feeding soil; because their haulm, or straw, running to a great largeness, cannot be supported without good juices and moisture; that white chalky ground, though in never so good heart, will be unfruitful with white oats; and that a mixed mould, between white earth and red clay, of which there is a great deal in the hilly parts of Hampshire, is not feeding enough for them. The red and the white clays, when in good

heart, carry moisture enough, and are very fit for this grain.

The common allowance of seed oats is four bushels to an acre; but Mr. Miller rightly thinks three bushels more than enough: and the usual produce is about twenty-five bushels from an acre; though he observes, that he has sometimes known more than thirty bushels reaped from that extent of ground; and we can say with truth, from an accurate account now in our possession, that a gentleman who is indeed an excellent husbandman, has had, for a continuance, forty-eight bushels of oats from off each acre of his land sown with that grain. I do not mean forty-eight bushels of naked oats; for the produce of that sort is the least of any in bulk, because its grains are small and lie very close together; but they make up in value for what is wanting in measure. White oats always produce a greater increase than black oats. Mr. Lisle threshed a stack of twenty-eight loads of the former, and found it yield more grain than a stack of thirty-eight loads of the latter: and farmers in general account an ordinary crop of white oats as good as a middling crop of black oats. This last sort is also most liable to blight, especially if a hot summer follow a dry, cold spring, and the grain has been sown on lay ground. Their culture is alike; and the manner of mowing and ordering them at harvest exactly the same. Only it is to be observed, that white oats are apt to shed most as they lie; and black oats as they stand.

In the year 1709, Mr. Lisle sowed, in the beginning of May, in some of his wheaten ground, where the corn had been killed in the preceding hard winter, rath-ripe barley in one part, and short grained white oats, which he distinguishes by the name of white Poland oats in another. Both grains were sown on the same day, in an equally fertile, moist, and well-tilled ground. He made no doubt but that the Poland oat would be first ripe, and was therefore surprised to see the rath-ripe barley spring up soonest, by four or five days: but reflecting on the nature of each grain, he soon concluded the reason to be, that the oat having a double hull, and being consequently better guarded from moisture; could not imbibe the vegetable water so soon as the barley; but that, the texture of the flour of the oats, and the infolded fibres of the inclosed plant being softer, it would consequently grow faster. From hence he infers, that, to secure the growing of Poland oats without rain, they must be committed to the earth before it becomes so dry as is proper for the sowing of barley, not only because the oats require more moisture to make them grow, but also because they lie so many days longer on the ground, before they come up, than the barley does.

When oats are about four inches high, intelligent husbandmen run a wooden roller over them, after a shower of rain has softened the clods, by the breaking of which, in this manner, fresh earth is laid to the roots of the plants; their tillering is considerably increased, if they have not been sown too thick, and the surface of the field is smoothed; so that the mowers, at harvest, are able to cut close to the ground, as it is very fit they should, because oats seldom grow high. Both oats and barley should be carefully weeded.

Oats are ripe when the straw turns yellow, the grain becomes hard, and the chaff begins to open and shew the seed. When mowed, they are generally let lie some time for the dew and the rain to plump them, and make them thresh well, and, if weedy, to kill the weeds; but if rain wet them much, they should be carried off as soon as they can be got tolerably dry again, or they will shed; for oats may be inned the wettest of any corn, if the weeds among them be but dead. Even in very rainy harvests, when other grain is spoiled, this will receive little or no damage, the surface of its straw and ears being so smooth and compact as to turn off water, and of so dry a nature, that, though housed wet, they will not heat in the mow, or become mouldy, as other grain usually do. This is a vast advantage in northern climates, where the harvest is generally late, and the autumn wet.

M. Duhamel is strongly of opinion, that farmers, especially those who keep many cattle, would find their account in housing their oats directly, without letting them lie out after they are cut, as is the common way, that rain and dews may moisten, and consequently swell their grain. He earnestly advises husbandmen to try the experiment upon a part of their crop; "because," says he, "the fodder will by this means certainly be much better for cattle, and much less grain will be lost in the field. It may be objected, that these oats will be difficult to thresh; to which

which I answer, that if this be the only inconvenience, the superior quality of the fodder, and the saving of a quantity of grain, which would otherwise be shed, will probably more than pay the extraordinary wages of the thresher.

"But allowing that the oats thus housed cannot be threshed quite clean, and that some grain will necessarily remain in the ears, I say that this will not be lost to the farmer; for he is obliged to give his cattle unthreshed oats, and they will easily find the grains remaining in the straw, which will not perhaps exceed the quantity that would have been dropped in the field: and even granting, though it will not happen, that the greatest part of the grain be left in the ear, still it will not be lost in the hands of an intelligent farmer; for what should hinder him from giving it to his horses? Supposing that four sheaves yield a bushel of oats, he need only give his horses those sheaves instead of a bushel of corn. They will certainly be longer in feeding upon four sheaves, than upon a bushel of cleared oats; and at the same time they will eat some straw with corn, which will supply the place of other fodder, and probably prove a more healthy food." This method may be particularly beneficial to such as live in very hot countries, or in very dry seasons.

Mr. Lisle, refuting the opinion of those who think that oats cut green will ripen while they lie in swarth, says, "If by ripening be meant shrinking, drying, or withering, I must allow the position; but if the countryman will have it, that the greenish oat, cut a fortnight or ten days, or be it but a week, before it is ripe, will proceed in its vegetable increase, and swell as well as harden by lying in swarth, I must deny it. This year (1707), I made a full experiment of this matter; for when the spring corn was sown, the ground being generally dry, half the oats and barley came not up till the latter end of May, when rain came, whereby in most places half the crop was edge-grown. The forward oats being then in danger of shedding, we were forced to cut down the greenish corn with the ripe, when otherwise we should have waited ten days longer. I let them lie in swarth about a week, and, when I carted them, I found the hull of the greenish oat had got a riper colour, and the pith was hardened, but pitifully lean and shrunk; so that though this is to be done on necessity, yet it ought not to be practised with such indifference as is usual among farmers. Note, the pith of these green oats was well past the milk, and came to a floury substance."

The same gentleman adds, that oats are the worst of all grain to keep, because of the great moisture in them, and their consequent aptness to heat when laid in a heap; and that when the heat has been such as to spoil them for growing, their hulls look as red as a fox.

The meal of oats makes tolerably good bread, and is the common food of the country people in the North. In some places beer is made with this grain: in Russia, in particular, the poorer sort make with it a drink, which they call *quas*; but its principal use is for the food of horses, for which purpose it is reckoned very wholesome, being sweet and of an opening nature: but it must not be given them before it has sweated in the mow, or been otherwise dried, lest it should prove too laxative.

The very long drought of the summer 1762, shewed another very profitable use of oats on such occasions; and probably it will answer equally well in the winter. Some milk-men near London boiled oat-meal in the water which they give their cows to drink, and found that the expence was abundantly repaid, by the additional quantity of milk which these cows yielded more than those which had not this mash.

Mr. Marshall, in his Rural Economy of the Midland Counties, says, "this year (1785, September 9), I grew ten or twelve acres of oats, on a foul wheat stubble, once ploughed, by way of bringing it into course, for fallow next year.

"About two acres (a cool moist part of the piece) were sown the 7th of April; the whole being ploughed in March. But the remainder of the piece I suffered to lie unsown, for two reasons; the dryness of the soil, and the backwardness of the season: the fallow did not blow before the 16th of April; nor did the grossberry foliate, before that time.

"Nevertheless, I finished sowing the 18th April: not more to save appearances, than to endeavour to hit the middle way between the season and the sun: for, although I am clearly of opinion, that the latter ought not to be wholly attended to, yet it is more than probable, that it

should not be wholly disregarded; because, when the season is backward, it is generally rapid; and although oats, for instance, may be sown with the fallow, yet, before they have had time to prepare for a state of vegetation, and to struggle through the soil, the hawthorn may (as it did this year), have foliated; and it is, probably, the emergence of the plant, not the deposit of the seed, which ought to keep pace with the vegetation of trees.

"All the oats in the country (Mr. ———'s perhaps only excepted) were sown before the fallow blowed: in general, between the 1st and the 15th April.

"Those which were sown early, and immediately after the plow, before the frost had taken the surface, came away, at once, and looked beautifully: while those of No. 17, sown by the fallow, came up in patches, and made a very poor appearance.

"The plants, however, which rose, were strong, and of a good colour, with the ribbon broad; and, when the panicles pushed out of the hose, they proved to be unusually well corned; so that, before harvest, they put on the appearance, notwithstanding the season and the state of the soil, of a tolerably full crop: while those, which had been sown early, and looked so beautifully in the spring, dwindled away daily: becoming weak, short, thin, and scrawly; and, when they were mown, afforded no swath. Neither Mr. —, nor Mr. —, I apprehend, had a load an acre, notwithstanding the soil was evenly occupied; while in No. 17, where not half the seed vegetated at the time of sowing, and where, in many places, not half the soil was occupied, there was from a load to a load and a half an acre. Had the whole of the seed vegetated at the time of sowing (and that it did not vegetate then, was not owing to the lateness but the dryness of the season), there would, in all probability, have been, notwithstanding the droughtiness of the summer, and the condition of the soil, between two or three loads of well-corned oats an acre.

"The patch sown first, though peculiarly moist and cool, and fully furnished with plants, bore no greater burden, and much less luxuriant plants, than the part sown last; though of a drier nature and not half covered.

"Therefore, this year's experience, with oats, has strengthened my opinion of the propriety of sowing by the seasons, rather than by the sun.

"However, for the reason mentioned, it may be prudent in an early season to follow in a late one, to precede, the progress of spring.

"It may nevertheless be proper to remember, that this caution is drawn from reason, and not from the experience of this year: for the oats, sown two days after the ploughing of the fallow, were evidently stronger, more healthy plants, than those sown three days before the circumstance took place.

"It is observable, however, that the part sown first, was first ripe; and that the time of ripening, throughout the country, corresponded, in this case, with the time of sowing.

"Many oats, in different parts of the district, have this year been sheaved: namely, mown outward, gathered from the swaths, bound, and shucked; in order to be cut, with greater propriety, into chaf, or cut-meat, for horses, &c. &c. this year of scarcity of hay. Sheaf corn lies straighter in the cutting box, and is of course less liable to be cut at a double, than loose corn.

"The common price has been five shillings an acre, for mowing, binding, shucking, and raking.

"I had about three acres harvested in this way; partly for the purpose of cutting, and, in part, to secure the fodder, and to put it, as much as possible, out of harm's-way, this hazardous harvest. The rest, getting ripe too fast for the few hands I had in employ, I harvested in swarth.

"The whole received a considerable quantity of wet; and those which were exposed in swarth, were of course considerably hurt. The corn discoloured, and the straw withered; while those in the sheaves were little, or not at all, worse for the weather. The superior quality of the straw of those which were sheaved is, this extremely scarce year for fodder, worth ten times the extra labour. Indeed, if turning, cocking, extra trouble in carrying and ricking, the extra shedding, and the raking after the carriage, be taken into the calculation, the saving would perhaps be found on the side of the sheaves.

"Of this, at least, there is no doubt, that in a catching harvest,

harvest, the sheaving of oats, if hands can be got, is incomparably better management, than exposing them in swarth. For if mown oats be carefully gathered, and somewhat loosely tied in small sheaves, carefully set up, and securely covered, there is scarcely any harvest untoward enough to hurt them.

"In the harvesting of oats, the primary objects to be attended to, are the colour of the grain, and the sweetness of the fodder. Clean threshing is a secondary consideration; for, if a few light grains be left in the straw of oats, the fodder is the better, and the sample more slightly.

"Hence" oats should be harvested, as much as may be, in the shade; and, of course, in covered thucks, rather than in swarths, or in single sheaves. See YORK. ECON.

"But, in harvesting wheat, different principles take the lead. The colour is not an object; while threshing clean is of the first importance: for the grains which are left in the straw of wheat are not only lost, but the thatch is injured by them.

"Hence wheat cannot be exposed too much to the weather, provided it is not injured by sprouting: nor oats be dried too much in the shade, provided they will thresh without very extraordinary labour.

"A penny or two-pence a quarter, in the price of threshing oats, is inconsiderable, compared with sweet fodder and a bright sample.

"Oats in thucks, well covered, are nearly as safe in the field as in the rick-yard: and it matters not much whether they remain there a week, a month, or a longer time; provided, in the end, they be carried perfectly dry."

In his Gloucester Economy, Mr. Marshall observes, that "the wild oat, a plant unknown in many parts of the island, is here, as well as in Yorkshire, a most troublesome weed of corn. In general appearance, this plant resembles exactly the cultivated oat: in stem, blade, panicle, chaff, and kernel, they are the same plant; and, in colour, their seeds are subject to the same varieties: namely black, red, white. But, examined botanically, the wild oat differs, in three notable particulars, from *avena sativa*; which is described by Linnæus, as having "calyxes two-seeded; seeds polished; one awned;" whereas, the calices of the wild oat are two or three-seeded; the seeds covered with long soft hair; and all of them awned. Nevertheless, in one instance, I found the lower seeds of the panicle nearly smooth: this, added to the circumstance of the Poland oat (a highly cultivated variety) growing in calices one-seeded, and without any awn, renders it much more than probable, that the various sorts of cultivated oats are no more than cultivated varieties of the wild oat.

"Be that as it may, the wild oat appears to be as confirmed a native of this island, as any other arable weed which grows in it; and is, perhaps of all, the most difficult to be extirpated. It will lie a century in the soil, without losing its vegetative quality. Ground, which has lain in a state of grass, time immemorial, both in this country and in Yorkshire, has, on being broken up, produced it in abundance. It is also endowed with the same instinctive choice of seasons, and state of the soil, as other seeds of weeds appear to have. This renders it, what it is considered, a difficult weed to be overcome: for, ripening before any crop, it sheds its seed on the soil, where it probably finds safety from the birds in the roughness of its coat. Fallowing, hoeing, and, where it is practicable, giving a final hand-weeding, after it shoots its panicle, are the only means of extirpation."

The following Letter from Mr. Lamb, on the best Method of cultivating black Oats, and recommending more frequent Ploughings than any usually afforded them, will, we are persuaded, be acceptable to our Readers.

"Gentlemen,

"Having been for many years a practical farmer in the eastern part of the county of Essex, you will not, I hope, think me impertinent in troubling you on the culture of black oats, which I have very often to great advantage sown.

"Most of my neighbours prefer the white Poland oat, which may, I own, in some circumstances of soil and situation, be best. I prefer the black oats, because they are hardiest, for which reason they suit best with my convenience; for, as a considerable tract of the farm I occupy is light land, I am under a sort of necessity of sowing this

soil early, or, if a dry summer followed, I should have no return at harvest.

"Few people allow more than one ploughing for a crop of oats; but such as follow this practice are very wrong-headed; for they may assure themselves, that no crop pays better for ploughing than oats; and it is on this account that I generally give my land designed for oats three tilths; whence, I am morally certain, arises the largeness of my crops, for I have seldom under five, oftener six, and very frequently seven quarters from an acre, throughout a field.

"Your readers will not be surprised at my having such good crops, when I observe, that I almost every year sow some oats on a fallow that has been well dunged; and this I aver to be good husbandry, as it abates the rankness of the soil, kills many of the weeds, and prepares the land in an excellent manner for a succeeding crop of sweet wheat; but I must observe, that I always clear my land of the stiff oat-stubble before I attempt to plough for the wheat.

"I have already said that I sow black oats early on my light land: by early, I mean as early as the first week of February, by which time I have generally an opportunity of getting the land in proper order, for a light soil is soon wet, and soon dry.

"Let me mention once more to your readers, that it is on a light soil, which is apt to burn a crop, that I sow my black oats so early as the beginning of February; for should any of them attempt to sow them so early in a moist, cold, stiff soil, and a hard frost should follow, the young blade would, in all probability, be killed.

"I must also remark, that when I sow oats thus early, it is generally under furrow; yet I sometimes sow them broad-cast, and plough them in.

"The quantity of seed I for the most part use is about three bushels, which I find to be enough; nay, I have sometimes from only two bushels had a good crop; but then I have been particularly careful and attentive to the goodness of the seed, without which precaution I should not, unless the season had been very favourable indeed, have succeeded.

"I have found it a very good way to sow first half my quantity of seed under furrow, and afterwards, sowing the remainder broad-cast, harrow it in; and this is often my practice when I sow the latter end of February, or the beginning of March.

"When I sow oats after wheat, which however is not very frequently, I turn up the stubble as soon as I conveniently can after harvest, and leave it rough through the winter. The first fine weather after Christmas, I lay it down smooth with the harrows, and immediately give it a cross ploughing.

"As soon as February comes in, if it is not a hard frost, I make the land as fine as I possibly can by the harrows, raising a fine loose mould to the surface, which is to be the bed for the oats to lie in; for I sow my oats directly under furrow; after which I pass a moderate sized roller over the field, and then give a slight scratch with a pair of light harrows.

"This husbandry generally produces me a crop I have no reason to complain of.

"My chief reason for troubling you with this letter is, to endeavour to persuade my brother farmers that they do not, in general, allow their oats a sufficient number of ploughings; one being the stated quantity.

"If they would plough twice for this crop, they would receive more than twenty shillings an acre for their trouble; but if they would consult their own interests, and allow three ploughings, it would often make fifty pounds difference to them in a field of twenty acres: this they will, perhaps, think wonderful; but it is no less true.

"The black oats require particularly to be sown early, especially if the farmer wishes to have them of a fine glossy ebony colour, and that the crop should corn well; for if they are sown late, and wet weather follows soon after sowing, they will be apt to run all to straw; and if it be dry weather, and the soil gravelly, it is a chance but they are burnt up.

"I have found by experience, that black oats will yield a very large crop after turneps; and this I believe is simply owing to their being sown in a fine tilth; for the mould cannot but be reduced to very small particles, if a crop of turneps has been well husbanded, especially if it is in a light soil.

East of Chelmsford,
Essex.

I am, &c.

J. LAMB.

S U

Wild

Wild OATS, a species of oats difficult to be extirpated, where they have once taken possession; for ripening before harvest, and scattering their seed round them, they will remain in the ground till it is ploughed up again, though it be for a whole year, some say four or five years, and will then come up with the corn. The surest way to destroy them is to lay the ground down to clover, and to mow the oats and clover together before the oats are ripe.

OIL-CAKE. See **FLAX SEED.**

OILS, the beards, or prickles of barley, &c.

OLLET, fuel of any kind.

OMY, mellow; spoken of land.

OPE-LAND, ground that is loose or open, from its being ploughed up every year.

ORCHARD. Mr. Marshall, in his *Rural Economy of Gloucester and Herefordshire*, gives the following information, under the heads *Orchard* and *Fruit Liquor*:

"The cultivation of fruit trees, for the sole purpose of liquor, is peculiar to the western provinces. The southern counties, when the London markets are overstocked with fruit, make a sort of liquor from the surplus: but the eastern, the northern, and the Midland counties, may be said to be as much unacquainted with the business of a liquor-orchard, as they are with that of a vineyard. Even Staffordshire, which is divided from the cyder country by a narrow ridge of hill only, has not, generally speaking, a barrel of cyder made within it.

"Herefordshire has ever borne the name of the first cyder county: Gloucestershire, however, claims a preference in the two most celebrated fruit-liquors the district affords. Worcestershire and Monmouthshire have their claims of excellency. May-hill may be considered as the center of this division of the cyder country.

"Devonshire and its environing counties form another division; which, though upon the whole much inferior to this, produces one species of liquor (the coccagee cyder) which is in high estimation.

"Fruit-liquor is here an object of rural economy: and, though inferior to most other of its objects, was a secondary inducement to my visiting the district. In 1783, however, I was unfortunate: it was not a general fruit year. But this year (1788), has made up for the disappointment. There are men who will this year make a hundred hogsheads, that, in 1783, did not wet the press.

"But the management of orchards and their produce, though it enters into the practice of almost every occupier of land, is far from being properly understood. The primary object of farmers, in general, has been that of supplying their own immoderate consumption. The markets for sale liquor has hitherto been confined. In a plentiful year it has barely paid for the slavery of making it. But the late extension of canals, and other inland navigations, and most especially one which is now extended between the Severn and the Thames, together with the present facility of land-carriage, have already extended, and will in all probability still farther extend, the market for fruit-liquor; and there may be, henceforward, some encouragement for the manufacturing of sale-liquor; the right management of which is a mystery which few men are versed in, and which I have found somewhat difficult to fathom.

"I have, however, been the more diligent in my application to this subject, as it is an art which has never been duly investigated. The entire subject having never undergone an analytic examination, no man can be said to have had a view of it, sufficiently comprehensive, to raise every part to the requisite degree of perfection. The cydermen (the buyers of sale liquor), are far advanced in the ordering of the liquor, but are unacquainted with the management of orchards; while the occupiers of orchards are, mostly, as unacquainted with the proper management of the fruit they grow. A general view of the whole art cannot, therefore, fail of having its use; even in the cyder countries.

"In the orchards of this district, we find the apple, the pear, and the cherry. The last, however, is only found near towns, and in young orchards: and although it is probable that a liquor of some richness and flavor might be made, from a well-chosen variety of this species of fruit, I do not find that any attempt has been made, in this district, to produce from it a vinous liquor. Therefore, the apple and the pear, only, are here entitled to examination.

"Nature has furnished us with only one sort of each of

these species of fruit: namely, the common crab of the woods and hedges; and the wild pear, which is pretty common in the hedges of the district.

"Linnaeus, who knew all nature, takes no notice of the apple. He, as well as other botanists, considers it as a production of art: the various sorts, with which our orchards abound, being considered as no other than cultivated varieties of the *pyrus malus*, or crab; while all the rich and highly-flavoured pears, of which gardeners speak so learnedly, are considered as no other than artificial productions from the *pyrus communis*, or common wild pear.

"But we require not the assistance of botanic knowledge to convince us, that the numerous sorts of fruit, which are cultivated by orchardmen and gardeners, are not natural species.

"The huffcap, and the sack, are pears which have been usually grafted: and besides these and a variety of others, great numbers of kernel fruits are found among the pear-trees, as well as among the apple-trees, of this district.

"The production of orchard fruit, for the purpose of liquor, now requires to be examined in detail, agreeably to the subdivisions of the subject enumerated at the head of this article. But in giving this general view of the proper management of orchards, the practice of this division of the cyder country (so far as at least as it has come to my knowledge) will be found, in many particulars, improper to be held up as a pattern. The method of procedure, in this case, must therefore be, to select the best instances of the practice of these districts, and make up the deficiency from my own practical knowledge of the subject of planting; in order to endeavour to render this article, what I wish it to be, general and practical.

"Through the kingdom in general, we see apple-trees in no other situation, than in small inclosures or yards adjoining to a house or garden; having been planted, perhaps, without much regard either to soil or aspect: locality, alone, having determined the site.

"But in this district, locality, with respect to the homestead, appears to have had little weight in determining the situations of orchards: which we frequently see scattered about in every part of a township; perhaps half a mile from any habitation.

"In situations where orchard fruit is scarce, and where a considerable market for them is within reach, such orchards might be hazardous. But in this country, fruit is of little value, until it be converted into liquor: a change which thieves, petty thieves, at least, have not an opportunity of effecting with sufficient secrecy. Cottagers have no mills. The stolen fruit must be carried to a neighbour's mill to be ground. The neighbour knows each man's fruit, and the quantity he grows; and the robbery is of course detected. In small quantities, especially near towns, orchard fruits are no doubt stolen. But the theft is similar to that of stealing a mess of turneps in Norfolk: they are never missed; and the real loss is inconsiderable, except in some particular situations.

"Aspect is of much more importance, here, than locality, and appears to have had due weight in fixing the sites of orchards, in this district; for though orchards are found on every side of hills, the south east, with a screen to the north, seems to be the favourite aspect. The morning sun is esteemed genial to fruit: an old idea, and not merely a popular notion; though in some degree it may be deemed such.

"It is not probable that the quality of the morning rays is much superior to those of the noon-day or evening sun (the popular idea); but it appears demonstrably, that a south-eastern aspect collects a greater quantity of heat, and enjoys a longer day than any other aspect. It is noon before a western aspect reflects a ray. In the morning, it will frequently remain dewy and cold, several hours after vegetation has been roused, against an eastern inclination. The afternoon sun is, no doubt, more intense on the west than on the east side of a hill; but its duration is short. In an afternoon, the air is every where warm; and a regular supply of warmth appears to be more genial to vegetation than a great and sudden transition from heat to cold. The coolness of the evening comes on, and vegetation is probably checked as soon, or nearly as soon, in all aspects. Hence we may, I think, fairly conclude, that the south-eastern aspect enjoys more vegetative hours, and

and receives a more regular supply of heat, than any other aspect.

"Nevertheless, on a fruit-liquor farm, it may be prudent to have plantations in different aspects. Blights (whatever they are) appear to be communicated to the trees by the wind. In 1783, orchard-fruit was cut off in every situation, except a north-west aspect; in which I saw several orchards fully fruited.

"A northern aspect, however, has its disadvantage; and although it may, in this country, especially where the soil is warm, produce fruits fit for the purpose of liquor, yet, in the more northern provinces, it may be altogether inadequate to that purpose. A hill dipping to the south partakes of the nature of a south wall. The atmosphere, a few feet from the ground, is probably many degrees hotter on the south than on the north side of a regular hill: and the richness and flavor of fruit depends much on the heat of the atmosphere it matures in. The fruit of the branch of a vine, for instance, which is introduced into a stove or green-house, is much richer and higher-flavored than that of other branches of the same vine, which remain in the common atmosphere. Hence every means should be used to render the atmosphere of an orchard as warm as may be; to collect as much heat within its area as possible. Therefore, while it enjoys the morning sun, it ought to have a tall woody screen to the east, to break off the piercing winds from that quarter. The winds travel horizontally, or nearly so; while the sun soon gains a sufficient elevation to lodge its rays in the atmosphere of a screened orchard.

"Much has been said about fruit trees in hedges, in the cyder counties. But this should seem to be one of those wild ideas, which hasty travellers are liable to catch. Crab-trees, perhaps, are more common in the hedges of this, than they are in those of other districts; and hedge-crabs, here, as in other places, are sometimes grafted with apples; but I have met with very few instances, in which hedge-rows have been designedly, and regularly, filled with apple-trees. About Bromyard, I saw one or two instances, in which apple-trees form close woody hedge-rows; blowing out, on either side, over the adjoining inclosures. But the practice of planting fruit trees in hedges, I apprehend, has never been common, and is now, I believe, wholly laid aside. There are two disadvantages attend it: the hedge is inevitably destroyed, and the fruit is difficult to collect.

"It appears to be sufficiently well ascertained, in this district, that the same species of fruit, when produced on different soils, affords liquors of very different qualities. The fire-apple, on the limestone lands of the forest of Dean, yields a cyder which is marked by richness, (sweetness), and fulness of flavour: while the same apple, in the Vale of Gloucester, a strong, deep, rich soil, affords a liquor, whose predominant qualities, without great diligence in the manufacture of it, are roughness and strength. The Hagloe crab, too, seems to require a calcareous rock to give full richness and flavor to its liquor. The orchard which yields the nectarious juice, that has been spoken of, has for its soil a very shallow loam, lying on a soft, sandy rock, provincially a dunstone, which, on examination, proves to be pretty strongly calcareous; and is of a con-texture sufficiently porous and loose to admit the fibrils of vegetables.

"On the contrary, the squash-pear draws the finest liquor from deep strong land. A plug of soil, taken beneath a pear tree, in a celebrated orchard, in the township of Taynton, is a strong brown clay, without a particle of calcareous earth in its composition. Nor does the subsoil, a still stronger red clay, shew the least marks of calcareosity.

"I have observed a pear-tree flourish on the side of a cold blue-clay swell (Lassington Hill) where the soil is so infertile that scarcely any herbage, except the wood sedge, will grow upon it; and where the native crab evidently starves for want of nourishment. There are many similar swells scattered over this district; and it is probable that their value (at present very inconsiderable) might be advanced manifold, by planting them with some of the superior sorts of pear trees.

"This contrariety may be reconcileable in the specific qualities of these fruits. The juice of the pear is naturally saccharine; while that of the apple abounds with acidity; and, if we may venture to reason on a subject so little understood, as is that of the vegetable economy; what is more

likely to lessen the proportion of acidity, than the tree which produces it feeding among the calcareous earth, its natural destroyer?

"From the whole of the evidence collected in this district, I am inclined to believe, that there are many situations, even in the more northern provinces, notwithstanding the disadvantage of climature: in which, with due attention to aspect, a judicious choice of fruit, and proper management of the liquor, even cyder of the first quality might be made. Perry of a good quality, I am persuaded, might be made in almost any quarter of the kingdom.

"The seeds generally used, in this intention, are the kernels of cyder-apples, separated from the must, or residuum of the press. These are either sown in autumn, or are kept dry in sand, or otherwise, until spring; care being had, in either case, to preserve them from mice, during winter.

"When the production of fresh varieties is the principal object, or when fruits, which are yet too austere, require to be further improved by cultivation, seeds thus obtained may be eligible. But for fruits, whose flavour is already raised to the desired pitch, and more especially for those which have passed the point of perfection, as some of the dry spongy varieties appear to have done, the seeds should certainly be those of the natural species, the native crab, which most districts produce, and whose juice will generally repay the trouble of collecting.

"Farmers, in general, considering fruit-liquor as the beverage of their servants and work-people, have no stimulus toward excellency in the art, if it is but cyder or perry, and has body enough to keep; no matter for the richness and flavour. The rougher it is, the further it will go; and the more acceptable custom has rendered it, not to the workmen only, but to their masters: the cyder which is drank, in this, and all the cyder countries, with so much avidity and in such quantity, is a very different liquor to that which is drank in the rest of the kingdom. A palate accustomed to sweet cyder, would judge the rough cyder of the farm-houses to be a mixture of vinegar and water, with a little dissolved alum to give it a roughness.

"Men, in general, however, whose palates are set to rough cyder, consider the common sweet sort as an effeminate beverage; and rough cyder, properly manufactured, is probably the more generous liquor; being deemed more wholesome to habits in general than sweet cyder, even when genuine. That which is drank, in the kingdom at large, is too frequently adulterated. The cyderman cannot afford to lose an hogshhead: if it will not do, it must be doctored: or if sound, it may not be sweet enough for the palate of his customers; nor high enough coloured to please the eye; but the requisite colour and sweetness, he finds, are easily communicated.

"The great art, however, in manufacturing fruit-liquors, whether cyder or perry, is that of gratifying the palate and the eye with the juices of the fruit alone. And although farmers in general, more particularly the lower class, are very deficient in the management of their liquors, there are men, especially among the more substantial yeomanry, and the principal farmers who ferment their own liquors for sale, that are far advanced on the line of right management.

"Unfortunately, however, these men, priding themselves, respectively, on the superiority of their liquor (more perhaps than on any other produce of their estates) become jealous of their art, and are not sufficiently communicative with each other. Hence the difference in their several practices; and hence the present imperfection of the art. For although each man may produce good liquor, in his turn, no one, I believe, pretends to uniform success; to produce liquor of the first quality, with certainty.

"The seed-bed should be adapted to the intention. If new varieties, or the improvement of old ones, be the object, the seed-bed ought to be made as rich as possible: perhaps even a frame, or the stove, might be found eligible. On the contrary, if the preservation of varieties be all that is wanted, an ordinary loamy soil is sufficient. In either case, it is proper that it should be perfectly clean, from root weeds at least, and that it should be double dug, from a foot to eighteen inches deep. The surface levelled and raked fine, the seeds ought to be scattered on, about an inch asunder, and covered, about half an inch deep, with some of the finest of the mould, previously raked off

the bed for that purpose. During summer, the young plants should be kept perfectly free from weeds, and the ensuing winter may be taken up for transplantation; or, if not crowded in the seed-bed, may remain in it, until the second winter.

"The nursery-ground, like the seed-bed, should be enriched agreeable to the general intention; and ought, in common good management, to be double dug, at least fourteen inches deep; eighteen or twenty inches deep is always preferable.

"The seedling plants ought to be sorted, agreeably to the strength of their roots, that they may rise evenly together. The top or downward roots should be taken off, and, in this operation, the longer side rootlets should be shortened.

"They should be planted in rows, three feet apart, and from fifteen to eighteen inches asunder in the rows; care being had not to cramp the roots, but to bed them evenly and horizontally among the mould.

"If the plants be intended merely for stocks to be grafted, they may remain, as they generally do, in this and other districts, in this situation, until they be large enough to be finally planted out. But, in strictness of management, they ought, two years previous to their being transferred to the orchard, to be re-transplanted, into fresh, but unmanured double-dug ground, aquincunx, four feet every way, in order that the feeding fibres may be brought so near the stem (yet have sufficient room to form in) that they may be removed with it, into the orchard: instead of being, as they generally are, left behind in the nursery. Hence, in this second transplantation, as in the first, the branches of the root should not be left too long; but ought to be shortened, in such a manner as to induce them to form a regular, globular root: sufficiently small to be removed with their plant; yet sufficiently large to give it firmness and vigour in the plantation.

"If the raising or improvement of varieties be the object in view, the nursery-ground should be naturally deep and well soiled, and highly manured; and the plants repeatedly moved at every second, third, or fourth year, that they may luxuriate, not only in rich, but in fresh pasturage; thereby doing, perhaps, all that art can do, in this stage of improvement, towards giving freedom to the sap-vessels, and size and richness of the fruit.

"The intervals may, while the plants are small, be cropped with such kitchen-garden produce as will not crowd or overshadow the plants; the rows being kept perfectly free from weeds.

"In pruning the plants, the leader should be particularly attended to. If it shoot double, the weaker of the contending branches should be taken off. If the leader be lost, and not easily recoverable, the plant should be cut down to within a hand's breadth of the soil, and a fresh stem trained. Next to the leader, the stem boughs require attention. The undermost boughs should be taken off by degrees; going over the plants every winter; always cautiously preserving sufficient heads to draw up the sap; thereby giving strength to the stems, and vigour to the roots and branches: not trimming them up to naked twigs, as in the common practice; thereby drawing them up prematurely tall, and feeble in the lower part of the stems.

"The length of the stem, to which stocks are usually trained in this district, is six feet; sometimes to near seven feet; a height which is much preferable: half a rod high would be still more eligible. A tall-stemmed tree is out of the reach of stock, and is much less injurious to whatever grows under it, than a low-headed tree; which, while it is the cause of mischief, is itself in harm's way.

"The thickness of the stem ought to be in proportion to its height: a tall stock, therefore, requires to remain longer in the nursery than a low one. The usual size, at which stocks of the ordinary height are here planted out, is four to six inches girth, at three feet high: a size which they will reach, with proper management, in seven or eight years. The price of such stocks, in this district, at present, (ungrafted) is eighteen pence each.

"If a mere orchard be the object, namely, a plantation of fruit trees, placed in as close order as the nature of fruit trees will admit, the distance may be much shorter than in a fruit-ground, which, notwithstanding the plantation, is intended to remain an object of husbandry.

"In this district, we see fruit trees standing at all distances. In close orchards, ten yards seems to be a prevailing distance. But the proper distance in this case depends on

the natural growth of the given trees: from ten to twelve yards (half a chain) may, in this intention, be an eligible distance.

"In the grass grounds of Gloucestershire, and the arable fields of Herefordshire, twenty yards is a common distance: some I have observed with intervals of twenty-five yards. A chain's length (twenty-two yards) may be taken as a good medium distance.

"In this case each acre sustains ten trees; in that forty.

"In grounds, the trees should be planted in cross lines, for the convenience of plowing. In orchards, they ought to be set in the quincunx manner, that they may have equal room to spread on every side.

"The time of planting fruit trees is October, and November; or February, March, or April; according to the season and the soil. Where the soil is dry and light, autumn is preferable; as during winter, the soil has time, assisted by the winter's rains, to settle firmly to the roots. On the contrary, in a cold, wet situation, where the soil is tenacious, and the substratum retentive of moisture, the spring months are a more eligible season of planting.

"In taking up the plants, more attention is requisite, than is usually paid to this operation. Their future progress rests principally upon it. The roots ought to be as numerous, and as long as possible. For the purpose of affording immediate sustenance to the plant, and of giving it firmness and stability in the soil. Hence the impropriety of crowding the plants in the nursery: and hence the utility of transplanting them previous to the final planting.

"In pruning the plants, the roots ought not to be touched (except taking off the downward roots in the center), but the top should, at this time, receive the form which it afterward ought to take. The leader should be shortened, and the smaller side-boughs be taken off; leaving a proper choice of the larger side-boughs entire and untouched; except, when the root, for want of due transplantation, is weak. In this case, the top ought to be reduced in proportion, to draw up the sap; and in due time, to furnish proper wood for grafting. Hence these boughs should have a proper elevation; and should stand in different directions; that the tree, after it be grafted, may take a regular head. This pruning of the head lessens the power of the wind, and, at the same time, by assisting the roots, ensures, with common care, the success of the plant.

"The method of planting requires particular notice. The ordinary method in the Gloucestershire cow-grounds, is to dig a hole, wide enough to take the roots (if not very long); which being placed within it, the mould is returned upon them in the order in which it came out; carefully replacing the sods on the surface, that no grazing ground may be lost. A mode of planting, which is too common throughout the kingdom.

"A method, which is more likely to succeed, is this: the ground being set out with stakes, driven in the centers of the intended holes, describe a circle, five or six feet in diameter, round each stake. If the ground be in a state of grass, remove the sward, in shallow spits; placing the sods on one side of the hole. The best of the loose mould, place by itself, on another side; and the dead earth, from the bottom of the hole, in a third heap.

"The depth of the holes should be regulated by the nature of the subsoil. Where this is cold and retentive, the holes should not be made much deeper than the cultivated soil. To go lower is to form a receptacle for water, which, by standing among the roots, is very injurious to the plants. On the contrary, in a dry, light soil, the holes should be made considerably deeper; as well to obtain a degree of coolness and moisture, as to be able to establish the plants firmly in the soil. In soils of a middle quality, the hole should be of such a depth, that, when the sods are thrown to the bottom of it, the plant will stand at the same depth in the orchard, as it did in the nursery. Each hole, therefore, should be of a depth adapted to the particular root which is to be planted in it. The holes, however, ought, for various reasons, to be made previous to the day of planting. If the season of planting be spring, and the ground and the weather be dry, the holes should be watered, the evening before the day of planting, by throwing two or three pailsful of water into each: a new, but an eligible practice.

"In planting, the sods should be thrown to the bottom of the hole, chopt with the spade, and covered with some of the finest of the mould. If the hole be so deep that, with this advantage, the bottom will not be raised high enough

for the given plant, some of the worst of the mould should be returned, before the sods be thrown down.

"The bottom of the hole being raised to a proper height, and adjusted, the lowest tire of roots are to be spread upon it; drawing them out horizontally; and spreading them, in different directions, as the bird spreads its foot when it stands on a level surface; drawing out the rootlets and the fibres, which severally belong to them; spreading them out as a feather, or as the frond of the fern; pressing them evenly into the soil; and covering them, by hand, with some of the finest of the mould: one person steadying the plant, another adjusting and bedding the roots, and a third supplying the mould; which being raised high enough to receive another root, or another tire of roots, they are to be spread out horizontally upon it, and bedded in a similar manner: thus continuing, until every root be bedded, separately, horizontally (or somewhat declining), freely, yet firmly, among the best of the soil; great care being had to work the mould well in, by hand, among the roots beneath the crown, that no hollows nor false filling may be left: to prevent which, the mould, after the roots are all bedded, and covered some depth, should be pressed or trodden hard (according to the nature of the soil and the state of the season) with the foot: the remainder of the mould being raised into a hillock round the stem; for the triple use of affording coolness, moisture and stability to the plant.

"In forming these hillocks some little skill is requisite. The soil ought not to press against the stem much higher in the orchard, than it did in the nursery: yet it is proper that there should be a descent for rain water, from the stem; not toward it. To this end a dimple or little dish should be made on the top of the hillock; and, from the rim of this, the slope should be gentle to the circumference of the hole; where the broken ground should sink some few inches below the level of the orchard.

"Much of this will, no doubt, be deemed tedious and unnecessary; by those, I mean, who have been accustomed to bury the roots of plants, in the grave-digger's manner: but I can recommend every part of it, to those who wish to ensure success, from my own practice; in which this method of bedding the roots arose; and, in which only, I believe, it has been used.

"Plants which have been properly transplanted, in the manner recommended foregoing, whose heads have been judiciously lessened, and which have been planted in the manner here described, seldom require any other stay than their own roots. If, however, the stems be tall, and the roots few and short, they should be supported, in the usual manner, with stakes, or in a manner which will presently be mentioned.

"The methods of guarding young trees from live stock, in this district, are various: the cheapest, and perhaps the most common way, is that of sticking some tall thorns round the plant, at a distance from the root; binding the tops of the thorns with a withe, and the middle of them with another; forming them into a sort of cone round the plant. This, however, is only a slender guard; and the thorns are liable to chafe the stem of the plant. I have seen many plants materially injured by this method of defending them.

"Opposed to this, the most expensive guard, not unfrequently made use of in the cow-grounds of Gloucestershire, are four posts, put down, in a square, about the plant; with five or six short rails on either side. The expence of this, if done in a strong workmanlike manner, is too great for common practice.

"The next is three posts, set in a triangle, with rails in a similar manner.

"In Herefordshire, and on the Herefordshire side of Gloucestershire, where young orchards are kept under the plough, two posts only are in use; namely, one large post, slit with a saw, and placed flatway, with the faces to the plant; and about two feet apart; with rails on each side, nailed upon the edges of the posts. This is beautifully simple, strong, a sufficient guard, if carried high enough, and out of the way of the plough; which has, in this case, nearly the same possession of the ground, as if no trees were planted.

"In this case, however, the upper rails should be compassing (bowing outward) equally to protect the tops from cattle, and to prevent the stems from being chafed against them. If these posts were put down at the time of planting, setting them within the planting holes, the roots would not be afterwards disturbed; and, by means of hay-ropes,

the plants might be steadied between the lower rails, without the trouble or the danger of staking.

"In this and every other case, unless the lower rails be placed very near to each other, the bottom of the stem should be guarded against sheep; which, in winter, especially while snow is upon the ground, will peel off the bark of the young trees; and, in a few hours, destroy the whole plantation.

"The after-management of the stocks consists in watering them (if requisite) the first summer: not, however, in the ordinary manner, by pouring small quantities, from time to time, against their stems; but by throwing as much at once as the hole will imbibe, into the trench left within the outer ring, round the skirts of the hillocks: thus communicating coolness, and a lasting moisture, rather than a temporary wetness, to the immediate region of the feeding fibres. And, secondly, in cultivating the hillocks, so far as to keep the surface over the roots free from grass and weeds, and the skirts of the hillocks in a loose pulverous state, to induce the roots to spread horizontally on every side.

"In a plantation, whose soil is kept in tillage, less care is requisite than in a grass-ground plantation; in which the circles of broken surface, round the plants, should be kept hoed as a garden; and the covering of soil be from time to time carefully worked over with the spade. As the roots extend, the circles should be enlarged, by fresh rings of sward being cut off and inverted; in order to encourage, by air and pasturage, their farther extension.

"By old orchards, it appears that whip-grafting near the ground (letting the young plants remain in the nursery until fit to be planted out), has formerly been the prevailing practice. But, in this case, the planter must take the nursery-man's word as to the sorts, when he wishes to be on a certainty. He likes to see the grafts taken from a tree whose fruit he knows. Besides, it is thought that whip-grafting, upon free stocks, has injured some of the more valuable varieties of fruit. Be this as it may, the practice, at present, is in disrepute.

"The practice, which has lately prevailed, and which is still prevalent, is this: the stocks, having stood some two, three, or four years in the plantation, until they have established themselves firmly in the soil, and have acquired a fulness of growth, are cleft-grafted, in the following extraordinary manner:

"The entire head of the stock is cut off, horizontally, with a saw, about six feet high: higher if the stock will admit of it, and the sort to be grafted be inclined to form hanging boughs: while an upright close-headed sort may, it is thought, be grafted upon a still lower stock. The top of the stump, being cleft, the grafts are inserted, in the usual manner; by men who go about the country, in the grafting season, for this purpose.

"The method of defending the grafts put in, in this manner, is perhaps peculiar to this district. They are inclosed within a kind of open-work wicker basket, made somewhat in the manner of the bottle-maker's baskets (prickles), with split osier twigs, about the size of the finger. When they are put upon the stock, they resemble the top of a tunnel; about two feet high, and about one foot diameter at the top: they are, however, worked flat; somewhat in the form of the mount of a lady's fan; much broader at the top than at the bottom. The compost used in grafting having remained a few days to stiffen, the bottom part of the guard is wrapt tight round the stem, immediately below the loam, upon which it is bound with rope-yarn; fixing it in such a manner that the upper edge forms the largest circle its length will allow.

"These wicker guards, provincially called braids, are most ingeniously adapted to this mode of grafting; they not only guard against cattle, but prevent rooks and other birds from disturbing the grafts, before they be established in the stock; and, what is of singular advantage to some sorts of apple-trees, they set up a dropping head, giving the shoots (which afterward become boughs) an upward tendency.

"But this method of grafting has its disadvantage: in a fine young orchard, which has been grafted in this manner in the Vale of Gloucester, I observed, that several of the trees are faulty in the crowns of the stems, which are now eight or nine inches diameter. The defect is owing to one of the grafts having miscarried; by which means a lodgment being made for water, a decay of that side of the stump of the stock has taken place; creating a sore, which the surviving graft has not been able to heal; there

being now holes nearly large enough to admit the hand, almost to the center of the stem : a premature decay of the tree must be the inevitable consequence.

" In Herefordshire, I saw another orchard, (which has been planted in the same manner, and which has got about the same growth), in which the trees cleave in the crowns ; both grafts having in this case succeeded. The wind having split some of them, and others being in danger of sharing the same fate, the judicious occupier of this orchard has secured them with iron bolts, put through the crowns ; having a broad head at one end, and a long iron pin or key at the other. The heads are already overgrown, and some of the keys nearly buried.
